6. Remember that any strongly acid or even alkaline (from ammonia) urine, should be neutralized before applying the Fehling's Test, as diabetic urine quickly undergoes fermentive decomposition with the formation of lactic acid which will dissolve the sub-oxide of copper as soon as formed; again, urine undergoing alkaline fermentation holds a certain amount of the volatile alkalies in solution, which should be neutralized or boiled off, as they in turn would dissolve any small amount of reduced copper. If there be a large quantity of albumin present in the urine, it can best be removed by saturating with sodium sulphate crystals, boiling and filtering.

Substances in urine other than sugar, that reduce the coppor solution when heated, are uric acid, urates, xanthin, hypoxanthin, kreatinine, (5*) indican, pyrocatechin, (6) alcapton, (Boedecker) nephrozymose (7) (Béchamp) urohodinic and uroleucic acids, (Kirk) (8) glycosuric acid (Marshall) (9 and 10). The organic substances isolated from the urine by Boedecker and Kirk are said to reduce the copper solutions but not sub-nitrate of bismuth (6).

The therapeutic agents that reduce the copper solutions are, turpentine, chloroform, chloral, (which appears in the urine as urochloralic acid) (3), ether, carbonmonoxide, amyl nitrite, camphor, benzoates, curara, cubebs, morphine, salicylic acid, hydrochinon, phenol, benzol, tannic acid, salol.

Delicacy of the Fehling solution in the cold: 1. In testing the delicacy of Fehling's solution we placed five test tubes aside in a cold place for twenty-four hours containing equal parts of the Fehling and a (1), (½), (¼), (⅛) and ($\frac{1}{16}$ per cent.) of grape sugar. In all we obtained decided reductions.

2. At the same time we placed tubes away containing (1) Fehling and uric acid (2) Urates (from abnormal urine. (3) Xanthin. (4) Hypoxanthin. (5) Kreatinin. (6) Albumin. (7) Mucus. (8) Pus and mucus. (9) Solution of peptones; not obtaining the least sign of a reduction in any of the nine.

From our experiments with the copper solution, we consider a sure way to detect the presence or absence of an abnormal amount of sugar in a given sample, is to set away equal parts of Fehling and urine in the cold for 24 hours; when if sugar be present to the amount of 0.1 of 1 per cent. you will have a reduction of the red or yellow sub-oxide of copper: That you may have a large amount of uric acid, urates, pus, albumin, etc., that would on heating reduce the copper, but in the cold have no effect.

Bottger's Bismuth Test. (11) To a solution of grape sugar or diabetic urine add an equal volume of a concentrated solution of sodium carbonate, then add a small piece of the basic nitrate of bismuth and boil the mixture. The bismuth is reduced to a sub-oxide, the reduction being indicated by the change in color of the bismuth to gray and if sufficient sugar be present, to a black. As this is given as a reliable test in nearly every work on the subject and as it is so universally employed by physicians, it might be well to give in full the results of our experiments; using Nylander's modification of Bottger's test (12) we applied it to the urine, etc., in the following manner:

1 In a test tube containing three-fourths to one-half volume of urine, again heating to the boiling point. Of thirty-three samples of normal urine so treated, every one gave a marked reduction.

2 After fermenting normal urine with yeast we still obtained a reduction.

3 We placed seven samples of urine of high specific gravity, away in the cold with an equal amount of Nylander's solution and examined after 24 hours and no reduction had taken place.

We next placed equal parts of a 5,2 and 1 per cent. solutions of grape sugar and Nylander's solution away in the cold 24 hours with negative results. We found:

1 Heat must be used to bring about the reduction.

2 Every sample of normal urine tried in this way gave more or less of a reduction.

We desired then to find, if possible, the substance or substances in normal urine which gave the reduction.

Thinking that it might be some of the sulphur compounds, we boiled the bismuth solution with potassium sulpho-cyanide, taurin, etc., with negative results. Next the precipitate of bismuth reduced by heating with twelve samples of normal urine was washed thoroughly and tested for sulphur but found none. The question of

*See references to papers.

the sulphur compounds as giving the reduction being dismissed, we tested with glycogen, acetone, succinic acid, pepsin, etc., with negative results. Finally on applying dilute solutions of both albumin and peptones we obtained heavy reductions a .01 per cent. solution of peptones giving strong reduction, proving to our satisfaction that this reducing substance in normal urine was probably some intermediate protein compound as nephrozymase (6), described by Bechamp as always present in normal urine and which Leube regards as a mixture of an albuminous and of a saccharine body.

Moore's (13) or Heller's (14) Test. To urine add an equal volume of caustic potash or soda, specific gravity 1.014, and boil the upper stratum of the fluid; if much sugar be present a dark brown color will be produced in the heated portion of the fluid. To find the value and delicacy of this test a 1 per cent. solution of glucose was treated in this way and compared with thirty-three samples of normal urine, eleven of these samples produced even darker brown color than the 1 per cent. solution of glucose. In diabetic urine the color is probably due to the formation of glucic and melassic acids (6).

Mulder's or Indigo Carmine Test. (4) Render a solution of indigo carmine (1: 1000) alkaline with sodium carbonate, boil this with one half its volume of diabetic urine, when the color changes from blue to purple, purple-red, yellow, and finally to straw-yellow color, after cooling and exposure to the air the various colors are obtained in the reverse order, until the mixture becomes blue again.

1. We found that strong sugar solutions, (5 to 10 per cent.) had no effect upon the color in the cold.

2. Heat should be cautiously applied, for boiling equal volumes of the indigo carmine solution and normal urine for any length of time dispersed the blue color in every one of the thirty-three samples tried.

3. We found that by using certain precautions, this test can be used to detect the presence of sugar in urine containing 2 per cent. or over, in urine containing less than that it is absolutely worthless, as was shown by the following experiment: Pour indigo carmine solution to the depth of one inch in three test tubes, render strongly alkaline with sodium carbonate, boil and add not more than an equal amount of a 5, 3 and 2 per cent. solution of grape sugar in the several tubes and allowed to stand until cool. In the 5 and 3 per cent. tubes the color is completely obliterated, in the 2 per cent. tube the color is changed to purple-red; now in all normal urines tested we found that if you heated both before and after adding urine the color was completely destroyed by the organic matter present normally in urine; hence in applying this test never heat after adding the urine and if the solution to be tested contains 2 per cent. of sugar, the blue color will be changed to purple or completely destroyed.

Urates, uric acid, kreatinin and inosite gave negative results.

Lactose acts the same as glucose, (15).

Fermentation Test. Fill a test tube to over flowing with a feebly acid diabetic urine, add a small piece of German yeast, close the tube with a tightly fitting cork or rubber stopper which has a small glass tube passing through it with one end extending down into the solution and the other bent at right angles; vinous fermentation will take place and the carbonic acid gas will rise to the top of the tube and by its pressure, will force some of the solution out through the small tube. The test tube should be left in a warm place for several hours when the stopper may be removed and the carbonic acid tested with a lighted match. This is one of the most reliable tests for sugar in urine containing more than 0.1 per cent. (16) but a control or comparison tube containing some of the same yeast and distilled water should be prepared and placed by the side of the tube and urine, as some specimens of yeast give off from themselves small quantities of carbonic acid gas; hence the preparation of the control tube should never be neglected. Grape-sugar is said to be the only carbo-hydrate found in urine that is broken up by the action of yeast as milk sugar, muscle sugar, etc. do not take a part in the fermentation, (6).

Alpha Naphthol and Thymol, (*Molisch*, 17-22.) To 2 c. c. of urine add two drops of a fifteen to twenty per cent. alcoholic solution of alpha naphthol and thymol, after mixing add an equal amount of strong sulphuric acid, a deep violet-red color with naphthol and a deep red with thymol will result if any carbohydrates or glucosides capable of yielding sugar (23-24) with sulphuric acid be

present. On diluting with water a violet blue precipitate is thrown down, soluble in alcohol and ether with a yellow color and in caustic potash with a golden yellow color; Molisch claims he can detect 0.00001 per cent. of sugar with his test, (3).

On applying this test to thirty-three samples of normal urines we obtain the reactions as stated above. This was sufficient evidence for some investigators to claim the presence of a small per cent of sugar in all normal urine. Before we accepted this statement however we wanted to prove by experiment that no substance other than sugar found in normal urine would give these color reactions. We submit in short the results of our work: uric acid, urates, xanthin, alloxin, allantoin, kreatinin, hippuric acid, potassium sulphocyanide, succinic acid, sodium and potassium phosphate, sodium chloride and sulphate gave no reaction: urea gave a slight red color with thymol but not with alpha naphthol; phenol gave the color reaction with both; peptones, a strong purple color with naphthol, none with thymol; inosite and lactose, none with naphthol; splendid reaction with thymol; acetone with thymol, none with naphthol; pepsin with thymol, not with naphthol; albumin in dilute solutions with thymol, slight with naphthol; finally normal urine after fermentation gave good tests with both. From the above tests we can see the reaction in normal urine need not of necessity indicate the presence or absence of sugar or carbo-hydrates, as any of the proteid substances as well as any of the phenol group will do the same. However if sugar be present in urine such urine can be diluted to such an extent that normal urine would give little or no reaction. Fifty per cent. of normal urines will give but a very slight trace of reaction after adding 100 volumes of water; others bear 150-200 dilutions, while some gave no reaction after the 50 dilution. Diabetic urine gave the reaction after being diluted from 300-400 times its volume.

Safranine Test, (25). Boil 1 c. c. of urine with 5 c. c. of a 1:1000 solution of safranine and 2 c. c. of caustic potash. Decolorization denotes diabetic urine; on cooling, the solution becomes turbid, unlike Fehling it is not affected by uric acid, kreatinin, chloral, chloroform, peroxide of hydrogen, or the salts of hydroxylamine. In using the test as given above, we found that every one of the thirty-three samples of normal urine would destroy the color if the boiling was continued any length of time. Three samples of normal urine after fermentation also gave reaction for sugar by this test. On trying several of the aniline dyes it was found that methylene-blue gave the same reaction.

Picric Acid Test, (26). Add to the urine an equal volume of a saturated aqueous solution of picric acid, and after the subsequent addition of a little potash, heat gently, when a marked reddish brown coloration will show itself. This change of color is due to the formation of picramic acid. By means of this color test Dr. G. Johnson makes a quantitative estimation of the sugar in diabetic urine. (26). In applying this test to thirty-three samples of normal urine, seven out of the number gave about the same color that was obtained from a 1 per cent. solution of grape sugar. We found furthermore that unless comparison tubes containing known strength of grape solutions were used, this test cannot be used in the urine. Every sample of normal urine will give a marked reddish brown coloration as is described above. Picric acid solutions are reduced by kreatinin, kreatin, inosite, and urine of patients taking choloral or sodium salicylate, (28).

Phenyl-Hydrazin Test, (*Emil Fischer* 29-32). Ultzmann's method modified by Bond, (Appendix B. Hoffmann and Ultzmann's Analysis of the Urine; Translated by T. B. Brune and H. H. Curtis, 1889).

"Into a test tube five inches long pour phenyl-hydrazin salt to the height of about 0.4 of an inch; add powdered crystals of sodium acetate to the same height above, and urine to one-half the height of the tube. This gives approximately by weight, one part phenyl salt, two parts sodium acetate, and fifteen parts urine; shake the tube gently until the sodium acetate is dissolved and then boil carefully for half minute; set the tube aside and examine for crystals. It is claimed for this test that it does not react with normal urine, that it detects sugar in as small quantity as does Fehling's test, and that it reacts with all substances of the sugar class which reduce alkaline copper solutions; thus it reacts with glucose, levulose, lactose, cane sugar, maltose, and sorbin,

but not with inosite or trehalose. The reagent does not spoil by keeping and its mixture with urine being antiseptic, allows the crystals formed to be detected weeks after their precipitation."

In taking the proportions used above I found that considerable caution was necessary to obtain good crystals. Instead of using two to three volumes of the urine to one of the salts, I found that to be sure of obtaining the phenyl-glucosazon crystals, even when large quantities of sugar were present, you must be careful and add but little more of the solution to be tested than to cover the dry salts, for like many crystalline bodies, they will not form in an excess of water, even when the crystals are practically insoluble in water. Our application is as follows: Place in a test tube equal volumes of phenyl-hydrazin salt and sodium acetate crystals, and add just a sufficient amount of the solution to be tested to nicely cover the phenyl-hydrazin and sodium acetate salts; heat gently to the boiling point and while heating agitate the mixture so that the phenyl-hydrazin is brought into intimate contact with the solution, otherwise it would rise to the surface and sides of the tube, and on continued heating would decompose. If over two per cent. of sugar is present in the solution, after heating half a minute and placing tube to one side for fifteen minutes, when, if the test is carefully made, you will have almost a perfect mass of lemon yellow crystals, forming in bundles or sheaves. These crystals can be studied under the microscope; a one-half per cent. sugar solution, after standing one hour, began to form fine spider-webbed-like crystals; on the addition of a few drops of acetic acid, the crystallization was hastened. A one and one-fourth sugar solution stood twenty-four hours before good crystals were obtained, showing from this that the time required for the appearance of the crystals depended directly upon the amount of sugar present. The crystals will melt at 204° C. They are only slightly soluble in water. The crystals in the mother liquor were found insoluble in $HC_2H_3O_2HCl$, HNO_3, H_2SO_4, NH_4, OH; with NaOH and on standing exposed to the air, the crystals were gradually decomposed, the solution taking on a deep cherry-red color. KOH manifested the same action only the color of the solution was a light orange-red. In finishing I would say: 1. Use concentrated solutions. 2. If crystals do not form within a half hour, at the ordinary temperature, cool the test tube to the freezing point, add one or two minims of acetic acid, and allow to stand fifteen minutes longer, when if no crystals form, we may be safe in concluding that we have less than one-half per cent. sugar present. Every sample of normal urine tested gave negative results.

Diazobenzol Sulphuric Acid Test, (3). To twenty c. c. of urine in a test tube made strongly alkaline with caustic potash, add an equal volume of the diazo-benzol sulphuric acid solution, (1 : 50) made faintly alkaline with caustic potash.

If sugar be present, the urine is at first yellowish-red, gradually becoming darker, finally dark red, and if there be much sugar present, opaque, (34); when strongly shaken the froth is carmine-red. Acetone and diacetic acid have a similar reaction, (39). Caution should be used in applying this test as the reagent is highly explosive, (35). This test is not satisfactory and many others are more reliable.

Ruber's Test, (36). The urine is treated with an excess of lead acetate solution, filtered and to filtrate ammonia is added until a permanent precipitate forms. The fluid is heated but not boiled. If sugar be present, the precipitate formed on the addition of ammonia, gradually assumes a rose-red color which vanishes slowly on standing; more quickly on application of heat, (60°–70° C.) giving place to a yellowish coffee color. Milk sugar does not give this reaction unless boiled for some minutes. Upon repeated trials this test was not at all times satisfactory: a number of normal urines gave a slight reaction for sugar.

The Polariscope Test. A urine containing more than three per cent. sugar will give a marked polarization to the right, if no albumin be present; but as it requires some practice, and the expense of the apparatus will prevent its use becoming general, we make no mention; however, a saccharimeter introduced by Dr. Ultzmann and of comparatively small cost, is being recommended by many analysts. For particulars, see (28), (27), (6).

In bringing the review of the qualitative tests for sugar to a close, I may say: My

experiments have extended over a period of two years during which time nearly every test applied to urine has been carefully studied and the tests which present themselves to us as the most reliable and which are in vogue in our Chemical Laboratory are, namely: Fehling's (in the cold), Phenyl-hydrazin, Fermentation and Polariscope tests; furthermore, that the other tests on repeated trials do not yield results that in all cases are free from doubt.

FORMULÆ FOR STANDARD AND VARIOUS TESTS.

FEHLING'S SOLUTION, (4). Weigh out 34.65 grams of pure crystallized copper sulphate, pulverize and dissolve in 200 c. c. of distilled water until the solution has a sp. gr. of 1.14; then dissolve in this solution, 173 grams of crystallized rochelle salts, (potass. et sodii tartrate.) Gradually mix the two solutions and dilute to one litre, (1000 c. c.) Mixture is of a deep blue color and 10 c. c. of it will just be decolorized by .05 gram of grape sugar. This solution will decompose easily and should be tested by heat and if no precipitate is thrown down the solution is still good. Other authorities (6) advise the two solutions being kept in separate glass stoppered bottles and mixed as needed, otherwise if kept any length of time the tartaric acid changes into racemic acid which reduces the cupric salts.

SCHMIEDEBERG'S MODIFICATION OF FEHLING'S SOLUTION, (3). 34.634 grams of copper sulphate dissolved in 200 c. c. of distilled water, with 15 grams of pure mannite dissolved in 100 c. c. of water and 400 c. c. of a caustic soda solution, specify gravity, 1.145, and dilute with water to one litre.

PAVY'S AMMONIATED COPPER SOLUTION, MODIFICATION OF FEHLING'S, (3). Dissolve 4.158 grains of copper sulphate in water with the aid of slight heat. Take another bottle and dissolve 20.4 grams of rochelle salts and a like amount of caustic potash together; mix the two, cool and add 300 c. c. of strong liquor of ammonia, specific gravity 0.880 and dilute to one litre.

HAINE'S MODIFICATION OF FEHLING'S, (37). Take 3 grams of copper sulphate; 9 grams of caustic potash; 100 of glycerine and 600 c. c. of water.

BARFOED, (37). Mix 200 c. c. of neutral solution of copper acetate (1.15) with 5 c. c. of 38 per cent. strength acetic acid. Add a few drops of this solution to urine, boil and if sugar is present, a red precipitate is thrown down.

BARRESWIL, (37). Take 60 grams of potassium hydrate and 40 grams of neutral tartrate of potassium, dissolve in 200 c. c. of water and mix with a solution of 65 copper sulphate in 500 c. c. of water.

CAMPANI, (37). To a solution of concentrated sub-acetate of lead, add dilute solution of copper acetate; add to the urine and if sugar be present a yellow to orange-red precipitate occurs.

CAPPAZUOLI, (37). A solution of hydrated oxide of copper in potassium hydrate; blue color if sugar be present.

NYLANDER'S MODIFICATION OF BOETTCHER'S TEST, (12). Two grams of sub-nitrate of bismuth; 4 grams of potass. et sodii tartrate; 100 grams of caustic soda of 8 per cent.

BREWCKE, (37). Boil fresh sub-nitrate of bismuth with 30 grams of potassium iodide and 150 c. c. of water after five minutes add 5 c. c. of 25 per cent. solution hydrochloric acid.

DUDLEY, (37). The sub-nitrate of bismuth dissolve in nitric acid; add equal amount of acetic acid and dilute to 10 volumes with water; 1 or 2 drops of this to urine made alkaline with NaOH and boil. A gray or black precipitate shows the presence of sugar.

FRANQUI AND VAN DE VYRE, (37). Boil the urine with hydrated bismuth in potassium hydrate and a reduction occurs if sugar be present.

PICRIC ACID AND POTASH, (27). Use one drachm of urine and one-half drachm of liquor potassium; 10 minims of picric acid solution; dilute to two drachms with water and boil: If sugar be present the yellow picric acid is changed to the deep-red picramic acid.

CAILLIAN, (37). Shake two volumes of chloroform with four volumes of urine; shake and the sugar will be in the upper layer of chloroform.

CASAMAJOR, (37). Shake urine with methylic alcohol and if sugar be present a slight cloudiness ensues.

KNAPP'S (37). To 10 grams of mercury in water, add 100 c. c. of caustic soda (1.145) and dilute to one litre.

LINDO, (37). A solution in caustic soda or potassium of the yellow substance ob-

tained by the action of nitric acid on brucine; yellow and then intensely blue.

MAUMENES, (37). Soak strips of white woolen in a 33⅓ solution of the per-chloride of tin ($SnCl_4$), dry; when boiled with a glucose solution it turns brownish black.

MAZZARA, (37). Heat urine with chloride of nickel, and if there is sugar present it gives a green precipitate.

HAGER, (37). To 30 grams of red oxide of mercury, add 30 grams of sodium acetate, add 25 grams glacial acetic acid and 50 grams of NaCl and 400 c.c. of water; dissolve and dilute to one litre; add an excess to the urine and if sugar be present there will be a separation of mercurous chloride. (Hg_2 Cl_2).

POLLAECI, (37). Shake the urine with 4 c.c. of water, add one drop of watery solution of ferric chloride; add 6 drops of sodium hydrate solution, then boil and add 3 drops of sulphuric acid; cool and add a fresh solution of red potassium ferrocyanide. Blue color.

PRATESI, (after Horsley) (6). Dissolve 2.5 grams of caustic potash in 60 grams of concentrated liquid potassium silicate and add 2 grams of potassium bichromate. On a strip of tin allow 5 drops to dry, when testing heat the tin and the drops turn yellow color; add urine, and sugar if present produces a green color.

HUIZINGA, (38 and 39). Urine made alkaline with potassium hydrate, add a few drops of molybdate or tungstate of ammonium; heated to the boiling and then acidulated, carefully with HCl, when a blue color is developed if sugar be present.

TEST FOR CARBO-HYDRATES, (39). Make the urine alkaline with KOH, then treat with benzoyl chloride; all the carbohydrates in the urine will be precipitated.

CHLOROFORM INTERNALLY.

Dr. Steep (*Le Progrès médical*, No. 21, 1882) has employed chloroform internally in a large number of diseases. He has obtained no appreciable effects in diphtheria, whooping-cough, pulmonary tuberculosis, or acute gastric catarrh. If given in infantile diarrhœa, with a small dose of opium, it will arrest the disease. In old persons he employs the following formula:

℞

Vehicle	30–40 grams.
Chloroform	3–4 gtts.
Tr. opium	5–10 dgrams.
Subnitrate of bismuth	q. s.

FISTULA IN ANO—GENERAL CONSIDERATIONS—ETIOLOGY—SYMPTOMATOLOGY—DIAGNOSIS—PROGNOSIS.

By LEWIS H. ADLER, JR., M. D.,
INSTRUCTOR IN DISEASES OF THE RECTUM, PHILADELPHIA POLYCLINIC AND POST-GRADUATE SCHOOL.

A fistula which is not due to ulceration and perforation of the rectal wall from within is the result of a previous abscess. Such an abscess forms in the ischio-rectal fossa and although opened early by a free incision, even before the cavity becomes distended with pus, it frequently fails to heal. It may fill up and contract to a certain extent, but it does not become entirely obliterated; a narrow track remains, which constitutes the affection designated fistula in ano. Several reasons may be mentioned here as to why rectal abscesses should so frequently degenerate into fistulæ: one is that owing to an internal opening within the bowel, small particles of fecal matter find their way into the sinus, and then, acting as foreign bodies, prevent the healing; another cause assigned is, that owing to the frequent movement of the part by the sphincter muscles, sufficient rest is not obtained for the completion of the reparative process; and, finally, the vessels of the rectum are not well supported, and the veins have no valves; hence, there is a tendency to stasis which is unfavorable to rapid granulation. According to the authority of Mr. Harrison Cripps* if the fistula be divided, its surface will be seen to be lined with a smooth gelatinous membrane, which, when examined under the microscope is found to consist of granulation tissue exactly analogous to that found lining the interior of a chronic abscess. The leucocytes forming the outer wall of this membrane are but loosely adherent, and constantly becoming free, form the chief part of the pus which drains from the fistula.

RELATIVE FREQUENCY OF THIS AFFECTION.

In point of frequency, compared with other rectal diseases, fistula is next to hemorrhoids. This statement is contrary to the showing made by the published statistics of St. Mark's Hospital, as quoted by Allingham.* This table shows that out of 4,000 cases taken consecutively, and without selection, from the out-patient department of the hospital, there were 1,057 persons suffering from fistula, and 196 from abscess, of which latter number 151 subsequently became fistulæ, so that more than one-fourth of the above number of cases treated were fistula. Allingham also states that a recent examination of the records of the in-patients at the same institution, covering a period of some years, shows that two-thirds of those operated upon were cases of fistula.

Mr. Allingham† justly calls attention to one source of error, in drawing conclusions from statistics, which, is due to the fact that many patients suffer from more than one malady. He states that "it constantly happens that a fistula is found in connection with hemorrhoids either as the substantive disease or as a complication. Again, a fissure or circular ulcer often has a sinus running from it, so that that it may fairly be considered as the opening of an internal fistula, and the case called a fistula, or the sinus is not detected and the case is called ulcer or fissure."

Another fallacious element which should not be overlooked in the statistics of Mr. Allingham is pointed out by Mr. Chas. B. Ball.‡ St. Mark's has a special reputation for the cure of fistula. so that many persons suffering from that disease go there, and in this way the records are made to show an apparent greater frequency of fistula.

Mr. Ball also states§ that at the Dublin General Hospital, although fistula is common it is by no means the commonest of rectal diseases; and in his own practice this affection has not furnished more than one-sixth of rectal operative cases.

AGE AND SEX AFFECTED.—This disease is commonly met with during middle age, but it is by no means restricted to that period of life. Allingham states‖ that he has operated upon an infant in arms and upon a man over eighty years old.

‡The Rectum and Anus, p. 66.

§*Loc., cit.* p., 67.

‖*Loc. cit.*, p. 13.

Dr. Henry R. Wharton* mentions having seen a number of cases at the Children's Hospital, Philadelphia, among which he records a case of complete fistula in a child a few months old.

Causes.—Fistula in ano may originate in ulceration and perforation of the mucous membrane of the bowel, as the result of the irritation produced by fecal accumulations (arising from any cause, such as atony of the intestines, irregularity of habits, rectal stricture, etc.), or by foreign bodies, such as fish- or rabbit-bones, grape- or fig-seeds; etc; more frequently it owes its origin to an abscess, which is caused by injuries, such as blows or kicks upon the anus, or by exposure to cold, as from sitting upon damp seats,—especially after exercise when the parts are hot and perspiring; it may also arise from excessive irritation of the rectum, occasioned by the presence of any of the forms of parasites which frequent the anus and its immediate neighborhood.

Other predisposing causes are thrombosed veins and suppurating hemorrhoids. Abscess, and then fistula, may likewise supervene in fevers and certain depraved conditions of the blood such as frequently give rise to boils or carbuncles.†

Finally, a tubercular or strumous diathesis seems to be as potent a factor in the causation of fistula as it is in other suppurative troubles. The tendency to the occurrence of abscesses and fistulæ in phthisical patients has long been recognized and has given rise to some doubt as to the propriety of resorting to operative measures in such cases.

Varieties:—For all practical purposes we may divide fistulæ into the following four forms:—(1) the *complete* fistula, in which there are two openings, one in the rectum, and one on the skin more or less remote from the anus; (2) the *incomplete internal* fistula, in which there is a communication with the cavity of the rectum by means of an opening in the mucous membrane, but none with the external surface of the body; (3) the *incomplete external* fistula, in which there is an external opening through the skin, but no communication with the bowel; and (4) the *complex* fistula, in which there are many sinuses and numerous external openings. Some of these tracks run outward; some extend up the bowel, beneath the mucous membrane; whilst others travel round the bowel and open in the other buttock, giving rise to the so-called *horse-shoe fistula.* The second and third varieties named, are often spoken of as *blind fistulæ.*

Symptoms.—The symptoms of fistula are not easily overlooked. Occasionally there is considerable pain present, but more frequently only a feeling of uneasiness about the anus is experienced. When a fistula originates, as I believe it most commonly does, from a pre-existing abscess, there is a sensation of weight about the anus, swelling of the integument, considerable tenderness upon pressure, pain in defecation, and constitutional disturbance associated with rigors. These symptoms are relieved after the matter is discharged. In complete fistula in ano, and in the incomplete internal variety, the evacuations are streaked or covered with pus and mucus, perhaps also slightly tinged with blood.

The chief discomfort to a patient with fistula is the discharge, in a greater or less quantity, of purulent or muco-purulent matter which is kept up from the sinus so long as it remains unhealed, soiling the linen, making it wet and uncomfortable, and producing an excoriation of the nates. The discharge is not of itself sufficient to be a source of great exhaustion, and does not interfere with ordinary occupations, so that many patients have had fistulæ for a considerable length of time and have been conscious of no serious ailment. The escape of flatus and mucus from the intestine, when present in complete fistula, will prove a source of annoyance as will also the passage of feculent matter, which will be expelled should the fistulous channel be very full.

An attack of secondary suppuration is always liable to complicate the presence of a fistula, due to a stoppage of the track by small particles of fęces, or by exuberant growth of the granulations. Such a sequela, of course, is attended with pain, until a new opening is formed, or one is made by the surgeon. In some cases, the original fistulous track becomes re-established.

Fistula in some persons, more particularly those of a nervous temperament, produces an impression of physical imper-

*Keating's Cyclopedia of the Diseases of Children, Vol. III, p. 341.

†Allingham, *Loc. cit.*, p. 14.

fection and weakness in their organization, which renders them miserable. As in other affections of the rectum, various reflex or sympathetic pains are experienced in cases of fistulæ; they are referred to the back, the loins, and to the bottom of the abdomen. When such pains extend down the leg and to the foot, they are likely to be attributed to sciatica, unless the history of the case is carefully studied and a critical examination made.

Ocular and Digital Examination. —Preparatory to making an examination in cases of fistula, as well as in all other investigations connected with the diagnosis of rectal diseases, the bowels should be emptied by an enema immediately beforehand. This procedure not only renders the exploration of the part easier and cleaner but, in women especially, serves to quiet the patient's fears of any untoward accident occurring, and therefore facilitates the thoroughness of the surgeon's examination, by securing the cooperation of the patient, as, in extruding the parts, etc.

In order to examine a patient with supposed fistula, he should be placed in a recumbent posture on a table or an examining chair, preferably on the side on which the external opening is situated, with the legs well drawn up toward the abdomen and the buttocks brought to the edge of the couch.

The anus and the surrounding parts should be carefully examined to detect any apparent lesion. If the external orifice of the sinus is prominent or if there is a sentinel granulation present, the outlet of the fistula will be obvious; but where it is small and located between folds of the skin, its situation may be demonstrated by making pressure with the top of the finger in the suspected locality, which will usually cause a little drop of matter to exude.

The site of a fistula may often be detected by feeling gently all around the anus with the forefinger, and finding an induration which feels like a pipe stem beneath the skin. A probe should now be passed along the fistulous track. In doing this considerable care is requisite, and the utmost gentleness should be observed, bearing in mind that the probe is to be directed by its own weight through the sinus, and not by force applied by the hand of the surgeon. If it does not pass easily, bend it and see if it cannot be coaxed along the channel. In many cases, it will pass directly into the bowel; when the probe has been passed as far as it will go without using any force, introduce the finger gently into the rectum. This should be done subsequent to the passage of the probe as otherwise, the introduction of the finger into the rectum will set up a spasm of the sphincter muscles which will greatly interfere with the passage of the probe. When the finger is in the bowel, it will frequently come in contact with the probe, which fact demonstrates the presence of a complete fistulous track; in other cases the mucous membrane is felt to intervene between the digit and the probe. In such cases the internal opening generally exists but is difficult to discover, sometimes because the examiner searches for it two high in the bowel. Palpation with the sensitive tip of the finger will often render the presence of the inner orifice obvious, upon coming in contact with an indurated mass of tissue. If such a spot be felt, the finger should be placed upon it and the probe passed towards the finger. Make sure that the fistula is a complete one by feeling the probe touch the finger. There may not be an internal opening, if not, see how near the probe comes to the surface of the bowel.

If a doubt still exists as to the completeness of the track, a speculum may be introduced into the rectum and the outer orifice of the sinus injected with either milk or a solution of iodine, when if there be an internal opening, the appearance of the colored fluid within the bowel will set the question at rest.

If the inner opening is not discovered by these methods, the case must be looked upon as one of external rectal fistula.

According to Ball* in those cases where the probe passes away from the rectum and is directed along the anal fascia to the upper portion of the ischio-rectal fossa, or where the entire substance of the rectal wall separates the finger and the probe, the case is one either of external rectal sinus, or of fistula originating in the superior pelvi-rectal space. In such cases, Mr. Ball states "that we must go farther, and try and find the cause, such as diseased bone, etc.; and in the female a

**Loc. cit.*, p. 77.

vaginal examination may show us a uterine or ovarian origin. Where there are numerous external openings it is necessary to carefully probe all of them so as to determine whether they are all connected and the direction which they take. The upper limit of the separation of the mucous membrane should also be made out, and search should be made for the presence of more than one internal orifice, if such is likely to be present."

The presence of incomplete internal rectal fistulæ is more difficult to determine than the other varieties of this lesion which have just been considered. It is the most painful form, though fortunately it is of infrequent occurrence. Its orifice may be located anywhere in the rectum, but is generally found between the internal and external sphincters. According to Allingham*, the circumference of this opening is often as large as an English three-penny piece, its edge being sometimes indurated, at other times undermined. The feces, when liquid, pass into the sinus and create great suffering—a burning pain, often lasting all day after the bowels have acted.

In this variety of fistula the feces are coated, more or less, with pus, or blood, and a boggy swelling is noted at some portion of the circumference of the anus. A peculiar feature of this swelling is often noted—viz., its presence one day and its disappearance in a day or two, followed by an increased discharge of pus from the bowel. This fact is explainable by the closure of the outlet of the fistula, caused either by a plug of feces or as a result of inflammatory swelling, which allows the collection of a quantity of pus and the consequent formation of a boggy tumor. The swelling disappears upon the re-establishment of the communication between the bowel and the sinus, and is attended by the profuse discharge of matter previously mentioned. This phenomenon is repeated over and over again, and indicates the nature of the disease.

In other cases of blind internal fistulæ, if the orifice can be felt, or if it can be seen through a speculum, a bent probe may be introduced into it, and made to protrude near to the cutaneous surface of the body where its point can be felt.

Loc. cit., p. 21.

Diagnosis.—The methods of diagnosing fistula have already been sufficiently detailed. A few words, however, as to differential diagnosis may prove useful. Fistula frequently co-exists with other rectal diseases; it is therefore important that an examination should be carefully made, so as to exclude such lesions for instance, as the presence of stricture, malignant disease, hemorrhoids and other tumors, etc. A thorough physical examination of the chest should also be made, to ascertain the presence or absence of phthisis, which so frequently complicates fistula in ano.

Serious kidney disease should be excluded before recommending operation, for obvious reasons.

In cases of caries of the vertebræ, of the sacrum, or of the pelvis, fistulous tracks may form and simulate anal fistula. In such instances a careful investigation will reveal the true origin of the trouble, and will show that the case is not one of ordinary fistula in ano.

Course and Prognosis.—This disease, untreated, has a tendency to increase. The longer its duration, the more tortuous and complicated does it become. Hence the earlier a patient submits to treatment the more favorable will be the prognosis; and the time and extent of the treatment necessary to effect a permanent cure will be correspondingly diminished.

1610 Arch Street, Philad'a, Pa.

LYSOL.

Cadèac and Guinard (*Province Mèd.*, April 23rd, 1892,) have made a series of experiments on lysol, from which they draw the following conclusions: Lysol is superior as a microbicide to carbolic acid, creolin, cresyl, and other analogous products; it has not, however, any advantages over the antiseptics of established reputation. It is only really efficacious when used in solutions, which may be caustic and irritating. Although not destined to play a great part in surgery, it may often be useful in the prophylaxis and arrest of epidemics and epizootics. It is likely to be particularly serviceable in the disinfection of premises, privies, railway carriages, ships, wharves, stables, and cow-houses. It is readily soluble, sufficiently active and very cheap.—*Brit. Med. Jour.*

ELECTROLYSIS IN THE TREATMENT FOR THE DESTRUCTION OF SUPERFLUOUS HAIRS.*

By DR. I. N. BLOOM,
LOUISVILLE, KY.

I had the honor of reading a paper on this subject before the State Medical Society, in 1887. My object in addressing you this evening is to give you the deductions drawn from five more years of constant experience in the treatment of hypertrichosis. A more extensive contact with women whose faces were marred by this deformity has shown me its importance, and its effect, mentally and physically, upon many of those affected.

In the paper already referred to I cited case of a Swiss girl who had committed suicide despairing of any other relief from her trouble. Some two years ago another similar case came under my observation, and this with the melancholia and mental effect often noted in such cases, gives the affection greater importance than is usually attached to it.

In the five years which have elapsed since I addressed the Society, electrolysis has been given its proper place in the treatment of these cases, as the sole means by which the affection can be permanently removed. The principal objections to it are, first, the scarring which results in a certain percentage of cases; second, the pain attending the operation, and, third, the time required for the removal of a large number of hairs.

As regards the first, while slight scarring may occur with a certain frequency, which cannot be foretold, in the worst exples where the operation is properly conducted, the cicatrices are so slight as to be infinitely preferable to the original deformity.

A thorough knowledge of the operation, and its technique, and good judgment in its use in special cases, must govern; otherwise the operation is unsuccessful because of want of skill in the operator, or, where the current is too strong, scarring results.

Pain in the operation is always present; but with a greater knowledge and accurate measurement of the current, it has ceased to be a factor, and I have yet to see a patient who has been deterred from coming the second or third time, because of the pain produced by the first visit. It is best to prepare the patient for the pain she is to suffer. (My patients have been, with one or two exceptions, females). There is, of course, no practical method of local anæsthesia which will obviate the pain.

With a suitable light, which must be the very best, the patient must be seated in an easy chair with head-rest, the battery properly prepared, as I shall describe later on and the negative pole is grasped by the patient after the needle connected with the positive-pole has been inserted into the hair-follicle. After a short interval of which more will be said hereafter, the circuit is broken by releasing the negative pole, the needle is removed and the life of the hair is destroyed. This, in brief, is the operation.

I wish to speak in detail this evening of its technique. The kind and number of cells of a galvanic battery is immaterial, provided a current sufficiently strong, i.e., up to three milliamperes, can be obtained. Different operators prefer different batteries. I have used two kinds, and note no difference in the effect. In order to do good work, a galvanometer is not only much more important, but is absolutely essential. With it and a rheostat, all the other trivialities can be disregarded. I use a twenty-cell Waite & Bartlett battery, because I happen to own one, and it gives satisfaction. In the circuit I place the rheostat and galvanometer, the latter measuring milliamperes. I use all the cells in order that one shall not be used up more than another, and regulate the intensity through the galvanometer by means of the rheostat. In general, I aim to use the least number of milliamperes which in ten to twenty seconds I have found by experience suffices to permanently destroy the hair. This, I find, varies on different parts of the body, and not always with the coarseness of the hair. On the chin from one to one and one-half milliamperes for an average of fifteen seconds, is my rule. On the neck a little stronger, or the same number for a longer time. Scarring is most frequent on the upper lip, and, I believe, is often due to carelessness or ignorance of the operator.

*Read before Jefferson County Medical Society, July 20th, 1892.

Here one-half to one milliampere for ten seconds always suffices. The same measure holds good for hairs on the cheek.

I never like to operate with a stiff needle. I use a platino-iridium needle, although I imagine my flexible metallic needle might do as well. It is often necessary to bend the needle in order to get at hairs which would be inaccessible to one perfectly straight; as, for instance, such as are situated low down down on the neck. A steel broach is much more difficult to handle. The point should not be too sharp, as the "catheterization" of the follicle is rendered more difficult thereby.

The success of the operation is best told by grasping the hair with a pincette. When the papilla has been reached with a sufficiently powerful current, no traction is necessary: the hair comes away at a slight touch. It is best not to let them fall out, as it is often necessary to insert the needle a second time for hairs unsuccessfully operated upon, and this can only be determined by the resistance to traction at time of operation.

I regard a sitting of an hour's duration as the utmost limit:—Indeed, after seven years' work, I have come to the conclusion that a half hour is all that should be attemped by one who has to do the operation frequently. The strain on the eyes and on the nervous system is very great, and the work after a half hour is rarely as good as it should be. In an hour's time, I can ordinarily remove from sixty to eighty hairs, and of these, on an average but three to five unsuccessfully. Where a hair is operated upon a second time, there is no pain felt, as the first operation causes temporary anæsthesia for some distance around.

A very essential caution is that of not operating upon hairs too close together. Small vesicles are sometimes formed where two are operated on too close together, and the tissue between is destroyed by the electrolytic action, and scarring takes place. Wheals occur most often on the neck, and on the cheeks, but disappear in a few hours; rarely does one see more than minute punctures the day after the operation. A skillful operator draws no blood at all, as bleeding never occurs when the follicle only is entered. It is well to allow as long a time as possible to elapse between two operations, if the hairs are close together;—a week if circumstances will permit, otherwise four days, at least.

Except in trichiasis it is not advisable to operate on non-pigmented hairs; the point of exit from the skin cannot be determined accurately, and, besides, very often an appearance of baldness is left, which to say the least is not desirable. In non-pigmented hairs the per cent. of success is much lower because the papilla is missed so often.

It is well to have an assistant to keep time, and generally a friend of the patient will serve in that capacity. It is rather difficult to watch at the same time the galvanometer and the time-piece after the needle has been inserted.

The principal drawback is the danger of scarring, and patients who have been operated upon by inexperienced operators, hesitate to undergo a risk a second time. No battery is reliable without a galvanometer. The resistance to the current offered by different patients varies, as, indeed, it does in different places on the same patient. The batteries, too, vary, not only from day to day, in strength of current, but from hour to hour. One patient grasps the electrode more strongly than does another. It takes but a few minutes to regulate the resistance by means of the rheostat, and once having registered the desired number of millamperes, there is but little necessity for changing the rheostat in any sitting to maintain the required number.

In those patients who have practiced depillation, it is more difficult to insert the needle so as to reach the bottom of the follicle; the direction of the hair seems to be changed by frequently pulling it out. The use of depilatory powders has a similar effect.

Where a mole has growing in it a number of hairs, the removal of the hairs by electrolysis causes a disappearance of the mole, and usually without leaving a scar behind it. This is especially the case where the hairs cover the whole surface of the mole, and tolerably evenly distributed. It must not be forgotten, however, that wherever the hairs exist very compactly and they are all operated on at one sitting, a scar is bound to occur from the electrolytic destruction. Where a mole is non-hairy and elevated, and of some size, I transfix it in two directions, or more, if necessary, putting on a current of three

millamperes, and keeping the needle inserted for about a minute. In such cases the resulting scar is smooth, slight, and limited to the site of the mole; it does not involve the normal tissue as is apt to be the case with acids. I have taken off pedunculated fibroids from the face in the same manner. I have never yet had even a slight hæmorrhage.

I will not speak here of the use of electrolysis in the destruction of telangiectatic vessels, nor of its value in various forms of acne. In small growths of all kinds on the face, I prefer it to the knife and caustics, for reasons already mentioned. The operation is one which requires a certain amount of manual dexterity, together with a large amount of patience. I have removed as many as six thousand hairs from the face and neck of one lady; it is by no means uncommon to find a thousand pigmented hairs.

When the hairs have been allowed to grow long, by their growth they hide the entrance to the follicle, when they exist in large numbers. In such cases I cut them off to about one-quarter of an inch from the skin. It is best if the hairs have been plucked out, to allow them to grow at least one-tenth of an inch long before operating.

If all the hairs operated upon have been in a circumscribed place, there may be a sufficient amount of swelling to be temporarily disfiguring. This occurs most often on the lip. I advise my patients in such cases to bathe the face in water as hot as it can be born for a few minutes at a time, afterward applying Lassar's paste, or benzoated zinc ointment.

Dr. Bloom then reported briefly several interesting cases upon which he had performed the operation of electrolysis, illustrating same with his apparatus for the purpose.

DISCUSSION.

Dr. J. M. Ray: I have listened with interest to the reading of Dr. Bloom's paper, as quite a number of these cases come under our observation, especially where there are ingrowing lashes, and a number of them we operate upon. I formerly attempted more or less removal of the eye lashes, not in the elaborate manner as mentioned by Dr. Bloom, but with an ordinary galvanic battery, and the needle, a plain jeweller's broach. Dr. Bloom makes the statement that in all cases of trichiasis and distichiasis, the operation of electrolysis should be preferable to all other operations. We all know that trichiasis and distichiasis occur in the late stages of so-called granular lids, and in cases where as a result of long standing inflammation the conjunctiva becomes cicatrized, and the under surface of the lid becomes shorter than the outer surface, carrying the inner angle of the free edge of the lid with the contained lashes against the cornea. In some few cases, before the incurvation of the lid occurs, the inflammatory action extends below the mucus membrane and into the foot of the hair and thus partial trichiasis results. As long as cicatrization goes on in the conjunctiva, there is an increased tendency to incurvation of the lids and increased number of lashes that will brush against the cornea, thus keeping up the irritation.

The operations for remedying trichiasis and entropion, I think, I brought up at a meeting of the Medico-Chirurgical Society a few weeks ago, at which time I read a paper on "Plastic Operations about the Eye Lids." I am in perfect accord with Dr. Bloom in the statement that where there are a few lashes turned against the eye, the early removal by electrolysis is the method to be preferred: However, if you have a case where there is extensive cicatrization of the conjunctiva in addition to the in-turning of the lashes, you want to restore the position of the lid. The operations that we make on the edge of the lid are twofold in their nature, and really the primary part is the turning out of the inner angle of the lid margin,so as to prevent rubbing over the cornea by the sharp angle of the lid; in carrying the edge of the lid out , we also carry the lashes along with it.

In the majority of cases that I have operated upon recently, there has been extensive in-curvation of the edge of the lid in addition to in-growing of the lashes. I think where all the lashes are turned in, or, say, one-half of them, that the plastic operation, restoring the lashes to their natural position is more desirable than the removal by electrolysis,because electrolysis would produce complete baldness of the lid, which, as you know, is quite a deformity.

Referring to the cases Dr. Bloom has

seen which have been operated upon by occulists where there was great deformity as a result of in-growing tissues. Of course the result may not be perfect in all cases; while the lid may be in its normal position, still there may be a few lashes that continue to rub against the cornea on account of the operation not being infallible. In the particular case Dr. Bloom mentions, if he had seen the woman before I operated upon her, he would have noticed that every lash was turned in against the eyeball. I made an incision along the free edge of the lid and removed a piece of skin from the outer surface of the lid, leaving a gap along the edge to be filled by cicatricial tissue, thus holding the lashes away from the cornea. In the majority of cases, in addition to extensive in-growing of the lashes, we have in-turning of the edge of the lid, and in these cases I have employed Green's modification of Von Burrow's operation, and the results have been very satisfactory.

Dr. I. N. Bloom: Concerning the use of anæsthesia in these cases, I have a great many patients come in and ask if I use cocaine. Four or five years ago when cocaine was introduced, I used it in one or two cases when operating for the removal of hairs, injecting a small amount of cocaine; but I think the administration of it gave the patients more pain than the insertion of the needle without it. I would much rather stand the pain of having fifty hairs removed than the pain of one hypodermic injection of cocaine.

As regards Dr. Ray's remarks, I want to acknowledge that I overlooked the fact that the rough margin of the lid is an important factor in causing irritation. Where the trouble is purely and simply irregular hairs, I think these hairs might be trained. In many cases you can train a number of them to grow straight. I will further state that I never saw a slighter deformity after so extensive an operation, as in the case of the patient referred to me by Dr. Ray. Another thing I quite forgot to mention is, where the trouble is simply due to in-turning of all the lashes, and there is no roughness of the lids, the operation of electrolysis would not even be justified, because baldness would follow. An operation giving new directions to the lashes would be preferable, even with slight deformity, rather than remove all the lashes. Concerning melancholia resulting from this disease; outside of the two cases mentioned I know nothing.

It may be that my successful experience in the last few years has been owing to the fact that I have been lucky with my patients, but I think the per cent. is due to the use of the smallest amount of electricity and using it for a longer time than was formerly done. However, it is barely possible that I have just been lucky, and that a slip will come soon and scars will occur in a larger per cent of the cases. I do the operation very frequently, have had as many as three cases upon which I have operated in one day.

The distress with which some women observe these hairs I want to say is remarkable, and I will mention the case of a young lady who was placed in correspondence with me by a friend. She wrote me greatly exaggerating the number of hairs, stating the trouble and annoyance caused her, etc. I told her to let the hairs grow sufficiently long, then to come here and I would operate. The young lady came down and I found that she had about fifteen rather light hairs, which were very easily removed. This young lady who was only nineteen or twenty years old, had almost been a monomaniac on the subject for three or four years.

CANCER IN RELATION TO INSANITY

From a somewhat extended inquiry into the above subject, Dr. Herbert Snow, surgeon to the Cancer Hospital, London, concludes that:

I. "Cancerous disease among the insane is rare.—Among individuals with congenital mental deficiency it seems to be almost wanting.

II. "Cancer is not increasing in frequency among the insane.—This fact is of no slight importance in connection with the view of cancer, as specially a disease of civilization largely caused by depressive mental emotion; and with the explanation of its greater prevalence in recent years on the ground of the increasing wear and tear which the nineteenth century life involves.

III. "Cancer not uncommonly precedes and causes mental derangement without cerebral tumor formation.—It should rank among the recognized causes of insanity."—*Journal of Mental Science*, Oct., 1891.

Society Reports.

SURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, June 11th, 1892.

Dr. A. M. Cartledge, Vice-President, in the Chair.

RESECTION.

Dr. W. C. Dugan: I have two cases of resection to exhibit.

This patient was brought into the city hospital a few months ago, with acute inflammation of the elbow joint. He was admitted to the medical ward and had been treated by the physician in charge who thought the trouble to be rheumatism. The arm continued to increase in size, patient had considerable fever and great pain in the arm and was referred to me for operation. I decided after a thorough examination to do a resection making a long, straight incision over the posterior part of the elbow. This was done and we found a large amount of tubercular matter, and the bone very extensively diseased. I then resected the lower end of the humerus leaving just the epicondyle eminences in order to preserve the muscular attachment, making a convex section of bone. and then cut through the olecranon process and moved it on a level with the coracoid process and scraped all the synovial membrane out. The wound was filled with iodoform gauze and arm put up in extension. The arm was enormously swollen; the dressing was changed every three or five days and the splint removed in one week and the arm put in a sling. He now has practically no pain or soreness about the joint, has good movement and he is in good condition and is going to have a good arm. The operation was done on the first of March and he has improved all the time.

I desire to call special attention to the absence of lateral motion which is usually found after these operations, which I account for by the saving of the epitrochlea and epicondyle eminences to which are attached in part the lateral ligaments of the joint.

The next case is one that I have already reported, but have never shown him, hence my excuse for again referring to the case. This young man twenty-two years of age was in the city hospital a year ago, suffering with tubercular arthritis of the right knee. I decided to resect the knee joint and at the time of the operation was undecided whether we would do a resection or just an arthrectomy, so we made a transverse incision, sawing through the patella turning it back to find out if the condition of the bones were such as to call for the removal of the articulation or the scraping out of the diseased structure. But both the femur and tibia were extensively diseased, so they were sawn off and the synovial membrane all carefully dissected out. The operation was done and the leg put up in fixed dressing which was left on for three or four months. The dressing was then removed and the patient got along well, as you see here; he has as good stiff leg as one could expect to secure.

An interesting feature in the case was this: a few months afterward acute tubercular arthritis developed in the other knee; considerable fever, night sweats, etc., and the question was then what were we to do with it. I at once decided to open it, thoroughly washing out with bichloride solution and inject iodoformized oil and tamponing with gauze, and the result is here to-night to show for itself. The joint was thoroughly opened in the presence of the class on both sides and the tubercular material scraped out with my finger and Volkmann scoop, and the joint cavity treated as above indicated. It was then tamponed with iodoform gauze which was left in for about a week; at the expiration of this time the dressing was taken off, the gauze removed and the joint again filled with iodoformized oil, and left, I think, for three or four weeks. When removed the next time I found that the wound had healed entirely and from that time the patient had no more trouble. To-day but for the presence of the incision no one would suspect the joint was ever opened. I would have resected the other knee had it not been for the fact that he already had one stiff knee. I am confident that if the first knee had been treated as the last one the result would have been equally as good, for the symptoms were about the same.

I have treated a number of cases of tubercular arthritis and osteitis with iodoformized oil, and am very much pleased with it.

Dr. A. M. Vance: There is very little to be said about these two cases, except to compliment the orator. I congratulate Dr. Dugan upon the successful result and would like to ask if there was any complication or specific trouble in the last case exhibited.

Dr. W. O. Roberts: The first case exhibited by Dr. Dugan reminds me of one that I operated upon some time since. The patient was an engineer on the railroad. The operation was performed in about the same manner described by Dr. Dugan, and the results very gratifying; he is now able to run his engine.

The case of resection of the knee joint is of considerable interest and the operation seems to have been a very successful one. I also operated on a case of this kind some time ago, where it was found necessary to not only remove the cartilages but a considerable portion of bone, and I was very much afraid that leg would not grow any more; however, it did and there was very little shortening. The result of the other knee operated upon by Dr. Dugan I think is marvelous, perfect as it could possibly be and he is to be congratulated upon the outcome.

Dr. W. L. Rodman: These cases are certainly very interesting ones, and I have never seen better results from resection of the elbow joint. I had a knee case that I expected to exhibit here to-night, but the man was a little sick and could not come. More than a year ago a tinner was working on the roof of a house and fell and ran a rusty nail into the capsule of his knee joint. I saw the man in consultation a few days after the injury. Found he had a well marked synovitis of the knee joint, I decided that something must have gone into the joint, as I believed suppuration to have taken place, and the only thing to do was to make an exploration. I found nearly a quart of pus in the capsule of the knee joint, in addition a nail without head. I made a free incision on each side, introduced two large rubber drainage tubes through which the joint was irrigated twice daily for at least two weeks. The man has gotten along nicely and has as good a knee joint as he ever had.

Dr. A. M. Cartledge: I think the left knee joint case is one of intense interest, as it puts side by side here in a certain measure two operations: one the resection, the other the injection of iodoformized oil; I do not think we should attribute the great benefit to injection of iodoformized oil; I believe that in many of these cases of tubercular joint trouble, a simble free incision of the joint with thorough scraping out of the tubercular matter or without scraping if free drainage is established, will be followed by the same result as when iodoformized oil is injected. I do not want to be understood as speaking against this agent, but, I believe, the same results could be obtained by simply tapping the joint. I have read the very interesting and successful results reported by Senn who used the injection in cases of this character.

Dr. W. C. Dugan: I prefer the iodoformized oil and after reading Senn's reports on this subject I am thoroughly convinced that iodoformized oil has some especial effect in these tubercular cases. I believe that the surgical literature on joint troubles should be re-written. I think many cases of acute inflammation of the joints could be hurried to a favorable termination by opening the joint early. Dr. Vance was leaving the city and left in my charge a professional base ball player with an acute suppurative arthritis. We thought that by frequent aspirations we could get along without arthrotomy; after Dr. Vance left the symptoms became more severe, and so the joint was freely opened, washed out and treated as above suggested. The patient made an uninterrupted recovery, and to-day has as good a knee as anybody and is playing behind the bat as successfully as before the accident.

UNUNITED FRACTURE

Dr. W. O. Roberts: Here is a patient that was before this Society some time ago. He had his leg broken in a railroad accident on March 21st. 1891. It was a transverse fracture and as I reported it was dressed in plaster which was removed at the end of twelve weeks, and there was nothing but a fibrous union with comparatively little shortening, probably about one-half an inch. I then decided for the purpose of creating an irritation we would let the man walk about and see if we could not get a bony union. This he did for some time, but no union resulted. I then used a Smith's splint with no more favorable result. In October assisted by Dr. Vance we put the man un-

der the influence of chloroform and rubbed the ends of the bones together, Smith's splint was again applied and the man allowed to walk. But soon afterward he felt that the bones were slipping and the leg was growing shorter and shorter, until finally there was a shortening of about two inches, still he was able to walk with the aid of a cane. On the 8th of March 1892, a little less than a year after the original injury, we cut down on the fractu re Drs. Vance, Dugan, Hueser and Pearce assisting in the operation. We found the bones widely separated, there were no signs of a union whatever. The ends of the bones were sawed off in such a manner that we could in a slanting way draw them together. The ends of the fracture were then fastened together with a large bunch of silk-worm gut and the leg put up in plaster dressing. The man got along without any trouble for a week, at the end of that time there were evidences of suppuration. We removed the dressing and as anticipated, found some little suppuration had taken place. We washed it out thoroughly with peroxide of hydrogen and put the leg up again in plaster. There is now perfect union of the fracture, but there is still a small fistulous opening.

Dr. A. M. Cartledge: What was your idea in using silk-worm gut for fastening the ends of the bone together?

Dr. W. O. Roberts: There were two reasons: We thought we could better sterilize it than any other material, and then the silk-worm gut is less liable to break than silver wire. If you use wire for suturing bone, and draw it sufficiently tight to firmly hold the fragments together, it is very liable to break.

Dr. Turner Anderson: I remember at the time you exhibited this patient before the Surgical Society, you stated that a successful result was very rarely obtained. The question was whether it would be desirable to attempt the operation in this case, or let the man limp along in the state as presented. Now, is this result liable to be permanent?

Dr. W. O. Roberts: I think the result will be permanent. There have been a number of the kind operated upon in this city, and, excepting one, this is the only case I know of where perfect union has taken place.

Dr. D. W. Yandell: The same thing occurred to me as mentioned by Dr. Anderson, that is how many of these operations are really successes. However, in this case, it looks as if it ought to be permanent.

Dr. A. M. Vance: I saw this patient several times with Dr. Roberts, and assisted him in the operation, the result of which you see to-night. I believe in this case the result is going to be permanent. It is the first one I have ever seen where union took place after the operation. There is one point in the case that has not been mentioned: The shortening or slipping by of the bones was so great that it required all the strength of two men after we sawed off the ends to stretch the tissues to get the ends of the bone into apposition. I believe they would have remained so without any suture, and the perfect coaptation possibly explains the good union and result. I am glad to see the good result from the use of silk-worm gut, and think this case demonstrates it to be the best suture material for bone. I do not believe in silver wire at all, it always leaves a sinus, has to be cut out, and always breaks once or twice as a rule before you have drawn it sufficiently tight to do any good.

Dr. W. L. Rodman: This is certainly a most interesting case, and the only case of ununited fracture I have ever seen where the result was so gratifying. I have never cut down upon the fragments of an ununited fracture myself, but have assisted in four or five operations and this is the only one in which union has taken place. In the other cases there was no suppuration, and in this case there was free suppuration, which may have something to do with explaining the good result. A distinguished English surgeon while in this city last fall, operated on a case of non-union fracture of the ulna. The operation was done under strict antiseptic precautions and there was no suppuration after the operation. The result at the end of eight weeks seemed to have been all that could have been desired; there was an abundance of callus, which seemed to be very firm. At the expiration of ten weeks, there seemed to be a little motion at the seat of the fracture, and less callus than there had been previously. At the end of eleven or twelve weeks motion was quite distinct, there was less callus, and apparently no bony union

whatever. The case is no better off than before the operation.

I do not agree with Dr. Vance in what he says concerning silver wire always causing suppuration. This case I have just mentioned proves that it does not cause suppuration. A large amount of silver wire was used and none of it was seen afterward. It never caused any suppuration at all, and it is in his arm now. Certainly silver wire is just as antiseptic as anything that can be used in these cases.

Dr. A. M. Vance: I would like to ask Dr. Rodman how many times he has seen good results from the use of silver wire in the character of cases referred to.

Dr. W. L. Rodman: I only recollect one other case, but the fact is well established that silver wire is the least irritating of all suture materials.

Dr. W. C. Dugan: I agree with Dr. Vance in regard to silk-worm gut; I think it is better than any other suture material for the reason that you can apply it, and there is no breakage at all. I want to disagree with him, however, as to the disappearing of wire; I saw a case the other day that I operated upon a number of years ago for fracture of the patella using silver wire suture, and the wire is still in. Of course I recognize that we sometimes do have suppuration following the application of it. This is simply another case like that referred to by Dr. Rodman where the wire has remained in a number of years and has given no trouble.

Dr. A. M. Cartledge: I have had very little experience in suturing ununited fractures. In suturing the patella I have used the over-prepared gut. In the case I exhibited to this Society some time ago who was operated upon for fracture of the patella, gut was used for suture, and the patient is able to walk as well as he ever could. I still believe that the over-prepared gut is the best suture material.

In regard to the production of callus; I question if suppuration adds anything to the production of true callus. I think if we do a perfect operation and by artificial means protect the formation of callus, there is very little reason for irritation. Certainly I cannot see how a suppurative process adds anything to or induces the formation of callus. In a simple fracture the formation of callus is greater than in a compound fracture which suppurates. Now, I believe that in the fracture of bone surfaces, if we maintain perfect apposition for twenty-five days, the uniting process will be so far advanced, if it is going to unite at all, that it needs no assistance from artificial means, between the fractured ends, hence the futility of agents which remain after that period.

In this connection I would like to make a continued report of a case mentioned at a previous meeting of this Society: I refer to the man having a compound fracture of the forearm, both the radius and ulna were broken and a fragment one and one-quarter or one and one-half inches in length was broken entirely out of the ulna, there was also perforation of the radial artery. The broken fragment was removed and thorough drainage established. In twelve weeks there was firm union of the ulna but the radius has never united. The arm at the time of operation was put up in plaster dressing and everything was kept perfectly aseptic. I propose in a few days to make an incision over the radius and unite the ends of the bone by a ligature.

Dr. W. O. Roberts: I have very little to add, except that I agree with Dr. Vance that it is probable no suture had been used the union would have been just as I believe the fragments would have remained in apposition. Treeves in his work on operative surgery, which has only been out a short time, advises that no material be used to fasten the ends of the bone together. He says all that is necessary is simply to saw off the ends of the bone and put on a plaster dressing which will hold them in apposition. This is what I believe.

Dr. D. W. Yandell: Do you think the surgeon as a rule sutures the bone for the purpose of keeping up irritation?

Dr. A. M. Cartledge: Partly, but it is more to obtain a perfect apposition.

Dr. D. W. Yandell: Then why do you remark at the end of twenty-five days is no need for further apposition?

Dr. A. H. Cartledge: If we can maintain perfect apposition for that length of time, I believe union will have taken place, provided it takes place at all.

Dr. D. W. Yandell: Do you mean to say that catgut is the best suture?

Dr. A. M. Cartledge: That is my opinion.

Dr. D. W. Yandell: There are so many different kinds of suture material,

that the world will never agree to which is the best.

PLACENTA FROM A CASE OF PLACENTA PREVIA.

Dr. Turner Anderson: I beg to exhibit a placenta from a case of previa; patient thirty-four years of age; in her third pregnancy. The membranes are intact except at point ruptured in treatment. One-sixth of the mass was inserted over the os, (previa partialis). First hæmorrhage occurred at seven months, was controlled by rest. Feeble pains and severe flooding came on one month later, which was temporarily controlled by efficiently applied tampon. I saw the case in consultation a few hours afterward; upon removing tampon the os was found dilated to about the size of a silver dollar. The pains were feeble and infrequent. The vagina soon filled with blood and very active hæmorrhage recurred. It was deemed unwise to further rely upon tampon, and the patient being given chloroform the attached portion of placenta was freely separated and membranes ruptured. The breach was found presenting, and a foot was brought into the vagina, thus effectually plugging the os with half breach. Hæmorrhage at once ceased and case terminated in birth of still child.

Concerning the treatment of this condition: I think the obstetric maxim—"That a contracting womb when emptied of its waters, cannot bleed to a dangerous extent," a most precious truth, both in accidental and unavoidable hæmorrhage. I would advise the induction of labor in previa in all cases as soon as the condition is diagnosticated; control bleeding with tampon until pains occur, and then rupture membranes, detaching the placenta from the os as far around as possible. Usually this is enough—help with forceps or version if indicated, but, remember the maxim above quoted, and do not be too hasty.

Dr. W. C. Dugan: Did I understand you to say to say that the pregnancy was eight months advanced in this case, and you simply sacrificed the life of the child in order to save the mother? Do you not think it advisable in these cases to endeavor to save the child's life by Cæsarian section, since it is clearly demonstrated that the operation as regards the mother is not very much more dangerous than an ordinary laparotomy, and at the same time the child, if the operation is done early, will be saved?

Dr. Turner Anderson: Owing to the condition of the patient at the time, I did not think we were justified in attempting Cæsarian section. The life of the child was not considered.

Dr. W. O. Roberts: I have only seen one case of placenta previa, and in that case the woman came near bleeding to death. It was a vertex presentation and I did as Dr. Anderson has suggested; that is, tamponed the vagina until uterine section came on, then ruptured the membranes and accomplished delivery. In this case both the mother and child lived.

Dr. W. C. Dugan: The question I asked Dr. Anderson is one that has been brought up a number of times in cases of advanced pregnancy, after the child has arrived at the age of viability, whether or not it would be best to perform Cæsarian section after applying the tampon. This operation has been very successful in a great number of cases of pelvic obstruction, both the mother and child being saved, and the mortality acccording to the reports of American and foreign operators is so low that the operation is one of the recognized surgical procedures.

Dr. H. H. Grant: I have seen three cases of placenta previa, only one of which I saw before the membranes had been ruptured. In one of these cases Dr. Anderson reached the patient almost as early as I did, and in a very few minutes with his assistance delivery was accomplished, saving both the baby and mother.

In another instance I saw the patient after tampon had been applied by another physician very effectually, but the patient was perhaps thoroughly exanguinated and labor was very feeble. She was delivered during the night, baby dead. The patient did very well for a few days, but on the sixth day developed septic fever and died.

The other case which I saw before the membranes had been ruptured, the os was very small, tampon was applied and kept in the vagina for twelve hours, then removed but the os was not dilated and it was again applied and removed at the end of twenty-four hours when the os was sufficiently dilated to allow introduction of the hand. This was carefully done and delivery rapidly accomplished. In this instance the mother recovered without any

difficulty, but it was evident that the child had been dead for at least twenty-four hours. I think we should rely upon the tampon to control hæmorrhage in these cases, changing it every twelve hours until uterine action is established and the os becomes sufficiently dilated to deliver the patient.

Concerning the point raised by Dr. Dugan with reference to performing Cæsarian section: This is answered by the fact that only with the most favorable surroundings is this operation justifiable, and it is the exception rather than the rule that we encounter those favorable conditions in the homes of our patients. If the patients could be placed in a hospital especially equipped for the purpose, then I should favor Cæsarian section, but, under the conditions in which we usually find them, I should be decidedly against attempting it.

Dr. J. G. Cecil: Dr. Anderson in his resumé of the modern treatment of placenta previa, has left us nothing to discuss. I certainly can find no point upon which I would in any way disagree with him. My experience in placenta previa is limited, but I have found the methods detailed so clearly by Dr. Anderson to be those which are the most successful in the cases I have had to deal with.

I do not agree with Dr. Dugan as to the advisability of Cæsarian section in these cases. I think it is an operation which can hardly become universal; in the nature of things it cannot, because these emergencies which arise in the practice of the general profession, that is, the general practitioner, so often are out of the reach of men who are capable of doing a Cæsarian section. Therefore, it is hardly necessary to consider it, outside of the centers of medical teaching. Then, again, those conditions under which Cæsarian section would be justifiable or advisable at all, are the very conditions which with the improved idea of managing these cases, I think, makes it rather against the use of the knife. In other words, I think cases may be managed in the manner laid down by Dr. Anderson with better hope of saving both the mother and child, than with Cæsarian section under any circumstances, at least it seems so to me. I take it if you please to operate upon a woman before she has lost much blood, before the rupture of the bag of waters, then the chances of Cæsarian section would perhaps be the thing comparatively speaking; but these are the very conditions which favor proper conservative management of these cases without the Cæsarian operation. For that reason it seems to me that the question of Cæsarian section in this class of cases will hardly gain much, if any, hold, especially among general pracitioners.

Dr. A. M. Cartledge: Cæsarian section in cases of placenta previa is a question that is exciting a great deal of attention, and I would like to hear it discussed at greater length.

OVARIAN TUMOR.

Dr. W. O. Roberts: The specimen which I exhibit is an ovarian tumor removed from a lady from a section of an adjoining State where very large tumors seem to develop, as this is the third one I have removed from patients in the same locality.

This patient was a lady sixty years of age; she first noticed the tumor about two years ago, because of the fact that it troubled her in stooping—she felt crowded about the abdomen. It is one of the largest tumors I have ever seen; it felt through the abdominal walls as though there was a great deal of solid material, especially on the right side. The patient was put on the table to be operated upon, and we detected in the lower part of the abdomen just above the pubes a rather diffuse lipoma. A large incision was made extending about an inch above the umbilicus; the first cyst we encountered was punctured, containing about two and one-half gallons, and after emptying it we were enabled to partially deliver the tumor through the abdominal incision, then it became necessary to open another cyst, and I believe before the tumor was entirely delivered, there were three cysts opened. There were no adhesions whatever of the tumor to the wall or to the intestines, but there was an adhesion of the intestine to the pedicle. After removal of the tumor there was no vessel to be ligated at all after ligation of the pedicle, but for fear the adhesion of the intestine to the pedicle might give rise to some trouble, I detached it. The cavity was thoroughly washed out and a drainage tube introduced. The tube was just long enough to reach to the bottom of the pelvis and it is one of the longest that I ever had used. I exhibit

the tube here in order that you may see its length. The operation was done last Saturday morning at ten o'clock, and Saturday night at eleven o'clock I was summoned hurriedly to the patient, the message being that she was bleeding profusely. When I reached there found her general condition good, pulse unchanged, temperature 99°. There was no evidence of loss of blood, but the bedding was considerably stained and the pus basin which had been placed between the patient's legs contained about four ounces of very red fluid. The drainage tube after the operation had been emptied every half hour and there would be at each aspiration of the tube from one to three drams of red fluid. This profuse flow came on after or during a severe retching spell. I felt satisfied from the general condition of the patient that there had been no considerable hæmorrhage, and that most likely this fluid was either some water which had not been emptied from the cavity, or the immense pressure having been removed from the walls of the abdomen, some of the capillaries had possibly given away and were oozing. Nothing was done except to remove the soiled dressings, and then to have the tube aspirated every hour. This (Monday) morning there was hardly a dram of fluid that came out of the aspirator and the tube was removed. The patient has gotten along without any elevation of temperature (over 99°) without any acceleration of pulse, and no pain.

Dr. A. M. Vance: I would like to ask Dr. Roberts if the hæmorrhage did not come from separated adhesions rather than from a new bleeding point. I do not think it is uncommon for points where adhesions have been separated to bleed moderately.

Dr. W. O. Roberts: I do not believe that the hæmorrhage could have been due to the separation of adhesions because there was only one small adhesion. There was no evidence of loss of blood, and the hæmorrhage might have been stained water left in the cavity from the operation, and the strain from retching brought the water out. Or, possibly the sudden removal of so much pressure upon the abdominal vessels caused the capillaries to dilate and some of the weaker ones may have given away, hence this accumu-

h however was slight.

Selected Formulæ.

INTESTINAL ANTISEPSIS.

℞ Salol .....
Salicylate of bismuth.....
Bicarbonate of sodium..... } āā 150 grains.

Sig.—To be divided into 30 powders in capsules. One capsule to be taken before breakfast and before dinner.

—*Dujardin-Beaumetz.*

NASO-PHARYNGEAL AND LARYNGEAL SYPHILIS.

Dr. Griffin (*Deutsche med. Wochenschrift*, No. 1, 1892) praises the following formula in the treatment of the naso-pharyngeal and laryngeal manifestations of syphilis:

℞ Calomel..... 4 grams.
Powdered opium..... 2 "
Lime water.....375 "

This is used, according to the severity of the disease, either pure or diluted with equal parts of water, as a gargle in pharyngeal phenomena, as an irrigant in the nasal manifestations, and as a spray in the laryngeal symptoms. He has obtained excellent results with this formula.

INTESTINAL FLATULENCE.

CACHETS.

℞ Powdered nux vomica.....1 gram.
Powdered anise. .....2 grams.

Mix, and dispense in 10 cachets. One, twice daily, before meals.

MIXTURE.

℞ Columbo ..... } of each, 3 parts.
Ether spirit.....
Star-anise tincture ..... } of each, 1 part.
Nux-vomica tincture.....

Twenty drops before each meal.

—*Potain.*

PARACREOSOTATE OF SODA IN THE INTESTINAL CATARRHS OF CHILDREN.

Dr. Egaye (*Bulletin générale de Thérapeutique*, January 30, 1892) recommends the following formula:

℞ Sodium paracreosotate.....1-2 dgrams.
Tinct. of opium.....2-4 gtts.
Cognac..... .....1 gram.
Syrup of gum arabic.....5 grams.
Distilled water .....25 "

A teaspoonful every two hours.

PLANT'S ASTHMA CIGARETTES.

The *Pharmaceutische Post* gives the following formula for these cigarettes:

℞ Stramonium leaves.....8 parts.
Pulverized green tea leaves.....8 "
Lobelia leaves..... .....7 "

Mix, and moisten with a saturated solution of potassium nitrate. Dry thoroughly and preserve in hermetically sealed cans.

MEDICAL and SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO
P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.
(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:
29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:
Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

—o—

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates).... $1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

HYSTERICAL FEVER.

The varied and peculiar manifestations of hysteria always form an interesting study, and as they are apt to prove most discouraging to the attending physician, any light on the subject is acceptable.

Hysterical fever has for some time been a recognized form of the disease. This fever is manifest either as a continued or paroxysmal fever. The continued fever is analogous to the continued sensitive disturbance, such as anæsthesia; while the paroxysmal form correspondes to the more transient anæsthesia and hysterical convulsions.

Naturally both forms of hysterical fever can follow each other in a complicated form, as well as in a series of lesser hysterical attacks, interrupted by more severe attacks; just so it is possible that during the continued hysterical fever, attacks of paroxysmal fever may also occur. Under the nomenclature of true hysterical fever, only such cases should be included where the temperature does not exceed 38.50° C.

Dr. Athur Sarbó, in the *Deutsche Medizinal Zeitung*, describes a well developed case of hysterical fever which occured at the Psychiatric Clinic in Budapest.

The patient, who was a girl sixteen years old, fell ill nine months prior to her admission to the hospital. The disease originated in this way, the patient had suddenly been brought in sight of a corpse, without having been prepared for the shock. She immediately fainted. She then became cyanotic, and had severe clonic convulsions, which, however, ceased when consciousness returned, but recurred again once or twice a week. The father of the patient was a hard drinker, and a relative on the father's side was neurotic.

The condition at the time of admission wsa as follows: The patient was a well-

nourished woman; the pupils were large, the right slightly the larger, but both reacted well. The sight of the patient was limited, and the right ear rather deaf. On the right side of the nose the patient could not detect the odor of acetic acid. On the right side of the face as well as of the body there was a complete anæsthesia of the skin, and also an absence of any sensation of temperature. On the right side no active movements could be made, and the temperature of this side of the body was less than that of the right. No other abnormalities could be found.

During her one month's stay in the hospital, the patient suffered occasionally from dizziness and constipation. Now followed the stage of fever. On the morning of November 12th menstruation began, the patient having a temperature of 38.9° C, and immediately after was seized with an hystero-epileptic attack, lasting twenty-three minutes. The following day the temperature was 38.5° C, and on the next two days it was 39.1° C.

For two weeks these attacks continued in spitė of the liberal administration of quinine, antipyrin, phenacetin, etc. No enlargement of the spleen could be felt at any time; during the fever both pulse and respiration became accelerated.

Regarding the ætiology of hysterical fever, Chau-Neau is of the opinion, that it occurs either primarily, without any assignable cause, or else secondarily, as a reaction of the strained nervous system.

According to Sarbó, hysterical fever is characterized by the very fact that there can be no reasonable cause found for its presence. The manner of the beginning of hysterical fever, its sudden appearance and disappearance, and its attitude towards antipyretics in general, make its diagnosis comparatively easy. Another symptom, although not always present, is a very high pulse, and but little rise of temperature. The therapy should be directed towards the disease rather than the fever. Symptomatically, antipyretics may be given, but they accomplish little or no good. The expectant treatment is about the best after all. If the fever lasts for several weeks general stimulants should be given.

INTERNAL ANTISEPSIS

Oddities and novelties in medicine form not infrequently quite interesting reading. In these days of skepticism an exuberant amount of faith in any method is pleasing to see. So it is with interest that we read the *Medicinische Neuigkeiten's* graphic, yet almost humerous, account of Dr. Vopelius' "New Theraphy," which he has recently advanced or rather hurled upon the medical profession as a finished work—a laurel crowned invention—which is destined (according to Vopelius) to reform the entire practice of medicine. Our esteemed German contemporary seems inclined to take the whole thing as a bad joke especially in the face of the present almost nihilistic attitude of the profession.

The principle of the new therapy, is simple enough, consisting merely in a system of treating all diseases antiseptically by means of suitable remedies given internally. It is said that "harmless" antiseptics are suitable for the cure of "all" diseases. Those best adopted for the new treatment include creasote, for chronic diseases; creolin, for affections of the vascular system; and lysol, in parenchymatous disturbances. In cases of fever, antipyretics and in old cases, iodide of potassium should be administered as well.

Traumatisms, crushes, as well as simple and complicated fractures heal "without rise of temperature, and in the shortest possible time" under the influence of creolin given internally. The influence of

creolin given internally in erysipelas, phlegmons, carbuncles, catarrhs and inflammation of the joints was "truly startling." Without the use of any external remedies, other than the necessary surgical operations, the diseases, says Vopelius, will be cured "in as many days, as it formerly was weeks, by the old method." The most severe cases of pernicious anæmia (chlorosis) disappeared in eight or ten weeks after the daily exhibition of 5.0 grammes to 8.0 grammes of creolin. Severe cases of scrophula, suppurations of the bones, amyloid degeneration of the liver, spleen, and kidneys, all recovered within three months. Old leg ulcers healed up after four or five weeks internal use of creolin, without any local treatment whatever; chronic polyarthrites, with beginning deformities, recovered within six months. If in such cases creolin does not prove of sufficient potency by itself, then, "creosote is called into action, as heavy artillery, in order to completely route and vanquish the foe."

Still more astounding are the virtues claimed for lysol. "Scarlet fever, measles, typhoid and diphtheria are no longer to be feared with this remedy at our hand" says Vopelius confidently. Two cases of diabetis mellitus were cured, three still under treatment are greatly improved, as well as two cases of Bright's disease.

"The greatest and most wonderful success," says Vopelius in thick, fat type, "that I have achieved by means of my internal antisepsis, has been the extraordinarily favorable action of lysol in carcinoma. For the past six months, I have been treating five cases of carcinomatous diseases, including one case of rectal carcinoma (in which specialists had already determined to perform extirpation of the rectum) one of carcinominata of the liver and peritoneum, one mammillary carcinoma (which also was to have been excised) and one carcinoma of the uterus, with large doses of lysol, giving daily as much as ten grammes. All five cases have improved to such an extent, that to-day I regard lysol as an unfailing remedy against this worst enemy of the human body." The "unfailing" is rather prematurely used to say the least. "The diagnosis" says Vopelius, "becomes greatly simplified." Perhaps even superfluous, näivly adds the Editor of the *Medicinische Neuigkeiten*.

"Since the bacteria is the disease *par excellence*," then "the seat of the disease is no longer of diagnostic importance, but rather, the nature and propagation of the germs."

Under the chosen heading of "nervous," Vopelius classes such diseases as neurasthenias, dyspepsia, epilepsy, etc.; these, he says, have their origin in organic disease foci, old scars, dyscrasiæ, commencing parasitic growths,etc.," Diseases such as scrophulosis, tuberculosis, carcinosis, etc., are directly hereditary (not the predisposition),in that the most minute ovulæ of the respective microbes of these diseases are contained in the semen of the man or the ovum of the woman.

There is a deep satirical vein in the remarks of the *Medicinische Neuigkeiten*, when its editor highly commends Vopelius, who being "merely a country practitioner," and not a professor in some great University permits the results of his discovery to be published in a local medical journal instead of telegraphing the same to all the leading newspapers of the country.

Editorially we graciously decline from making any comment upon the discovery of "Internal Antisepsis," leaving our readers entirely free to form their own opinions. Yet there may be some good in it,wild and as absurd as the scheme may seem. Vopelius writes in sincerity and from undoubted conviction, and the day may come when this form of internal antisepsis may be looked upon as a valuable therapeutic method—stranger things than this have happened; and after all "he who laughs last, laughs best."

Correspondence.

TREATMENT OF HICCOUGH.

Editor of THE MEDICAL AND SURGICAL REPORTER:—In your number of August 20 you gave some attention to hiccough, having three short articles, two of which deal with Leloir's method of digital compression of the phrenic nerve. I have used this method, together with a modification of my own, for a year and a half and have never had it fail, even in obstinate cases. I compress each nerve with the thumb and fingers of each hand, near the sternal end of the sterno-cleido-mastord muscle. Since hiccough is due to spasmodic action, or clonic spasm, of the diaphragm the efficacy of this mode depends upon the production of an inhibitory state in the phrenic nerve, the motor nerve of the diaphragm. Compression alone has sometimes failed to produce suppression of the spasmodic action—probably owing to difficulty in securing *perfect* compression, especially in the right nerve which lies a little deeper than the left. Therefore I supplement compression by the following: make the patient take deep, complete, slow, rhythmic inspirations (about 12 or 14 per minute) followed by similar expirations. These slow, rhythmic movements seem to effectually afford supplemental aid to compression in combatting the quick, jerky, spasmodic movements of the hiccough. In fact, this method has always succeeded, even in the *few* cases in which compression alone failed.

This treatment is not only more efficacious than medication, which is so seldom effective but is, moreover, practically instantaneous, its effects being observed in from one to two minutes.

Very sincerely,

CHARLES M. BUCHANAN, M. D.,

Washington, D. C.

ELIXIR OF CASCARA SAGRADA.

Dr. Dujardin-Beaumetz (*Le Bulletin médical*, No. 10, p. 179, 1892) proposes the following formula for an elixir of cascara sagrada:

℞

Fl. ex. cascara sagrada	āā 90 grams.
Glycerine	
Essence of orange	vi gtts.
Essence of cinnamon	ij "
Alcohol	200 grams.
Simple syrup	400 "
Water, ad	1 litre.

A wineglassful after each meal. Useful in habitual constipation.

Periscope.

THERAPEUTICS.

CHLOROFORM IN THE TREATMENT OF TYPHOID FEVER.

According to the *Lancet*, Dr. P. Werner has treated 130 cases of typhoid fever with a one-per-cent. solution of chloroform, the employment of which was suggested by Behring's observations of the germicidal action of chloroform upon the bacillus. Werner gave a tablespoonful of the solution every hour or every two hours during the height of the disease and for some days after the temperature became normal. In all cases in which this treatment was adopted before the tenth day great improvement was manifested; the tongue did not become brown, diarrhœa and tympanites gradually disappeared, there was no tendency to bed sores, and relapse was very rare. His observations agreed with those of Steppe, who used the drug in 1890 in this disease. Possibly we may have in this a desirable substitute for the so-called Brand treatment, of which Osler says in his recent work: "To transfer a patient from a warm bed to a tub at 70° F., and to keep him there twenty minutes longer in spite of his piteous entreaties, does seem harsh treatment, and the subsequent shivering and blueness look distressing. A majority of our patients complain of it bitterly, and in private practice it is scarcely feasible." —*N. Y. Med. Jour.*

ELECTROSTATIC TREATMENT OF STRANGURY.

Benedikt (*Wien. med. Presse*, No. 27, 1891) gives notes of two cases of strangury that were quickly relieved by applying the electrostatic douche and sparks to the spine and hypogastrium. Previous treatment had failed to ameliorate. Case I was tabes of long duration, strangury being the most distressing symptom. Relief of this condition was increased by each application. In case II the affection followed an operation for hæmorrhoids many years before. Immediately after the first sitting the number of nocturnal micturitions sank from twenty-five to nine. A fortnight's treatment reduced the abnormal state to a minimum. More recent successful cases lead him to view this therapeutical means as a specific.—*Brit. Med. Jour.*

FURTHER OBSERVATIONS ON EXALGINE.

Our knowledge of the therapeutical action of this, the latest addition to the invaluable series of analgesics, is gradually being extended. There are already very favorable reports by various competent investigators in the treatment of various neuralgic manifestations, and Dr. Gordon, of Aberdeen, contributes a further series of observations which seem to show that in doses not exceeding from four to six grains exalgine may be relied upon to relieve the pain in lumbago, intercostal and facial neuralgia, and similar painful manifestations of a neurotic type. In locomotor ataxy it abolished the formidable "lightning pains," and even the pain of rheumatoid arthritis, in a certain proportion of the cases, proved amenable to its analgesic action. Dr. Churton, of Leeds, on the other hand, contributes some interesting notes of a case of Graves' disease in which small doses of exalgine not only relieved the painful ocular symptoms, but determined the immediate subsidence of the local congestion. The genuineness of the effects thus produced was controlled by critical observations carried out with other remedies, all of which utterly failed to afford the relief which invariably followed the exhibition of exalgine. Dr. Churton's observations lead him to conclude that exalgine is in no sense a "cumulative" drug. In one case three eight-grain doses, equal to twenty-four grains, were taken within half an hour without giving rise to any symptoms beyond a feeling of being "dazed," with dryness of the mouth and fauces. This fact is interesting in view of the somewhat alarming effects occasionally reported as having followed even small doses.—*Med. Press.*

THE VALUE OF OPIUM IN MELANCHOLIC STATES.

At the meeting of November 27th, 1890, of the Netherland Psychiatric Society at the Asylum in Utrecht, Holland, the value of opium in melancholic states was discussed. Dr. Winkler sets forth two conditions in which opium is of value. (1) In anxious states; indeed, the writer has often succeeded in aborting these conditions by means of large doses of opium. (2) In alternating psychoses with insomnia; here small doses act best. Dr. van Parsijn would not be without the remedy. He has seen several cases of melancholia where the remedy gave good and lasting results; these were chiefly recent cases where the action was striking. He never uses morphine in such cases, but prefers opium. Dr. Doedes Breuning finds that the use of opium in the Dutch asylums is greatly decreasing. Dr. van der Sith would limit the use of opium to acute cases. He quotes Schroeder van der Kolk, who used it only in pure melancholia.—*Psychiatrische Bladen*, Deel IX, Afl. 1.

DIGITALINE.

Fouquet, in his study of digitalis, claims that it contains a well-defined, active principle possessing the valuable properties of the plant; the other constituents, which are less active, are sometimes sold under the name of digitaline. The following classification is made of the digitalines:

1. Digitaline soluble in chloroform and insoluble in water—crystalline digitaline, amorphous digitaline, digitoxine digitaline.

2. Those insoluble in chloroform and soluble in water—German digitaline, digitalein.

Of the above, only those of the first group should be used in medicine, preference being given to the crystalline digitaline.

He further concludes that digitaline should not be administered in granules, but advises it to be prepared in a standard solution made with glycerine, alcohol and water, each c. c. to contain one milligram of digitaline.

In addition to this, we may say that the varieties which have received the greatest amount of notice, are Homolle's amorphous digitaline, Nativelle's crystallized digitaline, and the soluble or German digitaline. Schmiedeberg claims there are at least five principles present in it, as well as the possibility of some products of decomposition. They are all nitrogenous, and with the exception of one *digitoxin*, are glucosides. "They are *digitoxin*, *digitalin*, *digitalein*, *digitonin* and *digitin*. The first three are cardiac poisons, digitonin acts like saponin, and digitin appears to be inert.

"Digitoxin is insoluble in water and forms the chief constituent of Nativell's digitaline. Digitalein differs from the two former in being readily soluble in water, and forms a large proportion of the soluble digitalin."

ARTIFICIAL PRODUCTION OF ABSCESSES IN PNEUMONIA.

L. Bard (*Lyon Mèd.*, April 17th, 1892) reports a third case in which the artificial production of an abscess by the subcutaneous injection of essence of turpentine see (*Epitome*, March 12, 1892, par. 223, and April 23rd, 1892, par. 370) in a bad case of pneumonia was followed by resolution and ultimate recovery. The patient was a man, aged 49, who had been suffering from pneumonia of asthenic type for nine days. As there was no appearance of resolution, and the patient was very weak and was steadily losing ground, three-fourths of a cubic centimetre of essence of turpentine was injected into the arm. The temperature fell the same evening, rising again the next morning in response to the local inflammatory reaction following the injection, and then gradually falling to normal. The patient's general condition showed marked improvement as soon as the suppurative process began, resolution took place, and the patient left the hospital completely cured. Bard points out that the case shows that the method is unattended with danger; his patient was in a state of grave adynamia with albuminuria and extensive atheroma of his arteries, yet no untoward effects followed the injections.—*Brit. Med. Jour.*

SOLANINE IN PAINFUL DISEASE OF THE STOMACH.

At a meeting of the Paris Academy of Medicine on March 22nd (*Sem. Méd.*, March 23rd, 1892), Desnos read a paper in which he recommended solanine as a useful substitute for morphine in painful diseases of the stomach. The drug is in a general way inferior to morphine, but it sometimes succeeds where the latter has failed, and it is likely to be of use where morphine is not well borne, or where the establishment of the moprhine habit is feared. Desnos has used solanine in a large number of stomach affections—gastralgia, dyspepsia accompanied by pain, alcoholic gastritis with or without dilatation of the stomach, etc. In a case of ulcerated gastritis with hæmatemesis, in a case of old gastric ulcer, and in some of cancer of the pylorous with vomiting, the painful symptoms quickly disappear under the use of solanine. Desnos gives the drug in pills, hypodermic injections causing too much pain. The usual dose is is 5 centigrammes given half an hour before meals; when the pain is very acute, solanine may advantageously be given in a gummy solution. The total amount given in the twenty-four hours never exceeded 15 centigrammes.—*Brit. Med. Jour.*

A TREATMENT OF SHOCK.

In the *Correspondenzblatt für Schweizer Aerzte*, 1891, No. 24, S. 745, Dr. A. Kottmann gives the details of the transfusion of salt water in the left cephalic vein to the amount of twenty-four ounces with a transfusion syringe. In cases when anæsthesia during shock is necessary he recommends ether instead of chloroform for this purpose. In cases of collapse, especially in pyæmic conditions, he combines these two method with success, operating under ether anæsthesia, and hoping, through the transfusion of salt water, to prevent shock, and as well to free the tissues from the poison. He cites successful cases in support of these methods of procedure.

STRYCHNINE IN INEBRIETY.

Dr. R. M. Phelps, First Assistant Physician to the Second Minnesota Hospital for Insane, gives in the *Hospital Bulletin* the following results of a series of investigations into the use of strychnine in inebriety:

1. Nitrate of strychnia, taken steadily in large doses, has a tendency, first, to impair the appetite for liquor; later, to make liquor an incompatible or sickening agent for *the time being*.

2. The systemic effects of nitrate of strychnia seem to be not injurious. Yet I would be far from advising any private or injudicious use.

3. Chloride of gold and sodium was only given in small doses the last five days of the twenty-one, and it is only mentioned here because it seemed to bring out a positive sickening effect in several who had before only a feeling of *indifference*.

4. The systemized methods of administration are important, because the physician is dealing with remedies in doses to be recommended only under close supervision.

MEDICINE.

THE PRODUCTION OF HEAT IN FEVER.

For many years a controversy has been carried on as to the cause of the rise of temperature in fever, one school arguing that such rise depended on increased oxidation, while the opposite school, of which Traube may be regarded as the exponent, considered the rise to be due to the retention of heat—that is, to a diminished discharge of heat by the body. With the view of settling this question, Professor Rosenthal (*Berlin. klin. Wochenschr.*, August 10, 1891) has recently, with the aid of his air calorimeter, carried out a research on the lower animals, using especially rabbits, in which pyrexia was caused by the injection of phthisical sputum, infusion of hay, etc. The result showed that the discharge of heat from the body was diminished, while the temperature was rising, Traube's view therefore being confirmed. The next point whsch Rosenthal set himself to investigate was whether during the onset of fever there was any increased production of heat, or whether the rise of temperature might be wholly due to diminished loss. The calorimetric experiments failed to supply any evidence of increased production of heat; in short, the rise of temperature appeared to be wholly due to diminished discharge of heat. Rosenthal is careful to limit the above conclusion to the animals under experiment (that is rabbits), in which pyrexia was produced in the manner indicated. A broader generalization must await further investigation. Nevertheless, a number of observations have already been made on sick persons in state of fever, and the evidence obtained, although not yet complete, points in a similiar direction, as stated above.—*Brit. Med. Jour.*

CROUPOUS RHINITIS.

M. Hunt reported a case before the British Laryngological Association. The initial symptoms were profuse, serous discharge from one nostril, with marked obstruction. Slight rise of temperature, 100° F.

The occluded nostril was lined with thick, white membrane. The mucous membrane of opposite side swollen and congested but without deposit. The deposit was removed easily, leaving a raw surface that bled slightly. The following day same deposit found in nostril, also on surface of faucial tonsils. The latter did not bleed on removal of exudate.

After removal, the denuded surface was brushed with sol. of argent. nitrat. (twelve per cent). The membrane disappeared fifteenth day from commencement of attack, and was followed by free mucopurulent discharge, lasting for ten days.

By microscope, the exudate consisted of basement of fibrin, fibrillous and granular, leucocytes and epithelial cells.

The absence of any nasal traumatism, of constitutional disturbances, of renal symptoms, and of diphtheria in surroundings, is the warrant for the diagnosis.

HEMIPLEGIA AFTER DIPHTHERIA.

Auerbach (*Deutsch. med. Woch.*, February 25th, 1891) reports the following case: A girl, aged 7, had extensive diphtheritic membrane on the tonsils and soft palate. On the eighth day of the disease the speech had a nasal twang, on the twelfth the urine contained albumen and casts, and on the fourteenth there was œdema about the eyelids. On the twelfth day the patient had convulsions for ten minutes, followed by coma, which lasted during the following night. There was almost complete anuria, but no vomiting or dyspnœa. The pulse was tense. The next day there was complete left hemiplegia, including the face, together with difficulty of speech, which latter passed off in a fortnight. The patellar and superficial abdominal reflexes were absent on both sides for a week. By the twenty-eighth day the œdema, which had been considerable, diappeared. In the seventh week the patient could lift the left leg about half as high as the right, and in the ninth week the arm began to improve. The recovery, though considerable, remained incomplete. The intelligence was unaffected. The author says that the hemiplegia was due to cerebral hæmorrhage, the onset excluding embolism, and that there were symptoms present in this case independent of the cerebral lesion, namely, paralysis of the soft palate, disturbance of co-ordination, and loss of reflexes. Auerbach then refers to the vascular changes found in the infective diseases and would attribute the

hæmorrhage to this fact, combined with the increased vascular tension brought about by the renal affection.—*Brit. Med. Jour.*

DILATATION OF THE CHEEKS IN GLASS-BLOWERS A CAUSE OF DISEASE.

According to *Le Progrés Mèdical*, the Sociétè de Biologie, of which M. Brown-Sequard is president, received from M. Regnault, of Marseilles, at its session on November 7th, 1891, a communication on a disease which is met with in about one third of the workmen. This condition does not attain complete development until the men have been from ten to fifteen years at the business. They are taken into the glass factories, usually, about fifteen years of age; and at first the young workmen complain of great fatigue and a painful feeling in the cheeks which extends to the ears; later, the cheek becomes gradually weakened, is easily puffed out, and the deformity, of which the cases presented were in an advanced stage, progresses steadily. This deformity is caused principally by the weakness of the buccinator muscle, whereby the cheek becomes swollen and permanently enlarged.

The swelling is limited by the masseter muscle. There is also a special dilatation of the duct of Steno, the calibre of which is increased and the orifice enlarged. This duct is filled with air, which may be forced out by pressure on the external surface, when a distinct gassy sound is heard.

The functional symptoms are inconsiderable. It happens very rarely that food is detained a moment between the cheek and the dental arch. There is no pain attending it, nor any disturbance of the salivary glands. Sometimes there is a thickening of the epithelium of the mucous membrane of the cheek.

RELATIONS OF ALBUMINURIA TO PSYCHOSES.

In an article on this subject Dr. Raymond says that the albuminuria present in mental disease, is either dependent upon the affection of the nervous centers, or is due to disturbance in the renal function, in which case it may become the direct cause of mental ailment; sometimes a relapse of the latter may go hand in hand with a return or increase of the albuminaria. In alcoholists the amount of albumin in the urine varied with the intensity of the delirium, and it often occurred in the delirium of alcoholism, when, in the case of death of the patient, no affection of the kidney could be found. In other forms of mental disease albuminuria is met with principally in the acute stage; frequently a certain relationship between the degree of the delirium and that of the albuminuria is noticeable. Upon administration of digitalis the œdema disappears, the albumin in the urine is increased, and the delirium passes away. The albuminuria, therefore, brings about a poisoning of the system, which, under certain circumstances, gives rise to the development of or causes an increase in the psychical disturbance. In the course of chronic nephritis delirium, simulating insanity, may occur with the uremic intoxication. The cases reported by the author illustrate this. The maniacal excitement, combined with religious and erotic delusions and hallucinations, occurred in individuals having no hereditary disposition during attacks of uremia of chronic nephritis. Dieulafoy calls this disease "folie brightique." The treatment of these cases does not consist of the application of the cold douche, nourishment, etc., but must be directed towards the affection of the kidney; exclusive milk diet.—*Centralblatt f. klin. Medicin.*

NOTES ON PRICKLY HEAT.

Dr. J. A. Wetherell, writes in the *Lancet*: Under the term "lichen tropicus" must be embraced three primary lesions, in frequency taking the following order:—1. A vesicular eruption, the vesicle, of the size of a pin's head, elevated on a roseolous, inflammatory base, being filled with colorless perspiration; sometimes arranged in segments of rings, at others diffusedly spread. On a superficial examination, it resembles much the efflorescence of measles or scarlatina, and occurs principally on the nape of the neck, the flexor surface of the forearms and legs, and the front of the abdomen. Even habitants for many years of semi-tropical regions are apt to exhibit this form, especially those who wear woolen underclothing. 2. A wheal with a red surrounding halo, accompanied by intense itching, which induces the sufferer to scratch off

the covering cuticle, causing the erythematous effusion to develop a blood-scab. Its characteristics are shown on the backs of the hands and about the ankles, and may be mistaken for mosquito bites. 3. A coppor-colored papule of largish dimensions, on whose surface after twelve hours may or may not appear a pustule. The front of the throax exhibits this best. The older pathology which regarded prickly heat (lichen tropicus) as a papular eruption, and the more recent, as vesicular—hence termed "miliara dapulosa"—are both partially correct, but also erroneous, inasmuch as they recognize a single lesion. The treatment of all consists in washing the affected parts frequently with superfatted menthol, euclyptol, or phenol (20 per cent.) soap, allowing the rubbed-in foam to dry, then mopping on with a soft linen rag this lotion: liquor plumbi subacetatis, liquor carbonis detergens, and glycerine, of each one ounce; rectified spirit of wine, three drachms; oxide of zinc, two drachms, to a pint of water; or smearing with the following ointment: vaseline, two drachms; lanoline, two ounces; liquor carbonis detergens, two drachms; oxide of zinc, one drachm; menthol, twenty grains. If of limited extent, a bismuth and zinc powder may replace these. Cotton underclothing should be adopted and frequently changed.

SURGERY.

IRREDUCIBLE DISLOCATIONS OF THE GREAT TOE AND OF THE THUMB, TREATED SUCCESSFULLY BY OPERATION.

Lloyd (*Lancet*, London, February 27, 1892) describes an operation for irreducible dislocations of the thumb and great toe, with a report of two cases.

The first case was a backward dislocation of the toe, the result of a fall from a horse. Attempts at reduction were made, but without success. An incision, two inches long, was then made, with its centre over the head of the metatarsal bone. The head of the bone was found thrust petween the heads of the flexor brevis pollicis. The anterior ligament, with the sesamoid bones, was torn away and had "shut back" behind the rounded head, constituting the chief if not the entire obstacle to reduction. The anterior metacarpo-phalangeal ligament was divided freely, freeing the sesamoid and permitting easy reduction. The wound between the ligaments and muscle was closely sutured, and the wound dressed antiseptically. The patient was about his work in a few weeks, and suffered no incouvenience.

The second case was a backward dislocation of the thumb, the patient presenting himself three months after the injury. A similar operation, as above described, was performed, and with a like result.

Lloyd advances several theories as to the cause of irreducibility. The one most generally accepted, is that the bone is tightly grasped by the two heads of the flexor brevis pollicis. A point of great importance lies in the fact that the head of bone pushes its way through the muscle, above the level of the sesamoid bones; the anterior metacarpo-phalangeal ligament being torn from its metacarpal attachment, these two structures, which are closely incorporated, "shut back" behind the protruding head and become closely applied to the anterior part of the articular surface of the displaced phalanx. The "shutting back" of the structures is due partly to their own elasticity, and partly to the pull of the short muscle; of the thumb and toe. In rare cases of dislocation of the thumb, the long flexor tendon gets between the ends of the bones. *Lloyd* thinks that excision of the joint, in these cases of dislocation, is necessary.—*Univ. Med. Mag.*

COMPOUND DEPRESSED FRACTURE OF THE SKULL, WITH VERY EXTENSIVE LACERATION OF THE BRAIN AND HÆMORRHAGE FROM THE SUPERIOR LONGITUDINAL SINUS.

By Dr. Bensel. Patient, thirty-eight years of age, was struck on the forehead with a heavy beer glass. Lost consciousness for a few moments only, then recovered sufficiently to walk. Was transferred to hospital. On admission was perfectly conscious, but very nervous and irritable. Pulse slow and full; pupils dilated; skin warm and dry; respiration normal. Extensive sub-conjunctival hæmorrhage, so that patient could with difficulty close the eyelids. A wound, two inches long, extended transversely across the middle of the forehead immediately above the supraciliary ridges, with extensive depressed fracture. Patient refused consent to operation until next evening, when sub-con-

junctival hæmorrhage had become so great that it was impossible for him to close his eyelids over the protruding eyeballs. The depressed portion of bone was found to be almost completely detached from the surrounding bone, and depressed for about half an inch, tearing the meninges very extensively. The removal of the detached bone was followed by a tremendous hæmorrhage from the superior longitudinal sinus. Author used the sliding catch of a Langenbeck artery clamp as a lever to control the hæmorrhage. There was a laceration of the frontal lobe of the brain on the right an inch and one-half deep, and one on the left nearly half an inch deep. Wound packed lightly with bichloride gauze; dressed and bandaged in the usual way. Patient made an incomplete recovery. —*New York Med. Jour.*, Jan. 16. 1891.

ANEURISM OF THE RENAL ARTERY.

Oestereich (*Berlin klin. Wochenscher,* 1891, No. 42.) publishes two cases of aneurisma arteriæ renalis:

1. Sacculated aneurism of a branch of the left art. ren. located inside the kidney. Dilatation and tortuosity of numerous branches of both renal arteries (particularly the left) in a case of endarteritis chronica deformans. Breaking through of the aneurism into the renal pelvis; rupture; death from hæmorrhage.

Patient was a woman æt. fifty, who had commenced to bleed from the genitalia fourteen days before death.

2. Sacculated aneurism art. ren. dextr. attached to the trunk of the vessels outside of the kidney. Patient a young man.

No symptom of aneurism during life.

According to Oesterich the local semiology of renal aneurism is:

a. The tumor. Aneurisms of a certain size easily palpated, eventually pulsating, lying behind the colon as a tumor. This is the most certain diagnostic sign of renal aneurism.

b. Auscultatory findings, systolic or diastolic gassy bruit.

c. Hæmaturia appearing first when perforation occurs into the renal pelvis.

d. Pain inconstant.

1, Renal calculus; 2, Renal tumor; 3, Renal rupture; 4, Hæmophilia renalis.

Prognosis bad, because the uncomplicated outcome of renal aneurism must be inevitable hæmorrhage.

THE OPERATIVE TREATMENT OF PERICARDITIS.

At the meeting of the (*Berlin Medical Society*, Jan. 6. 1892,) Dr. Kœrte reported a case of pericarditis which he had cured by operative measures. The patient, a girl aged seven years, had developed the disease as the result of osteomyelitis of both tibia. Aspiration of the fifth intercosal space furnished thin pus rich in staphylococci. The operator resected a portion of the fifth rib. 5cm. in length, opened the pericardium, evacuated about one litre of a thin purulent fluid. Although the heart was exposed by the incision, no disturbance of its function was observed, even after the pericardial sac had been thoroughly irrigated with a disinfectant fluid. The patient died twelve days after operation of cardiac failure. The autopsy demonstrated a number of pus channels in the left ventricle, some of which communicated with the pericardium, the posterior papillary muscles had been destroyed and the anterior was infiltrated with pus. It is probably that in this case abscesses first formed in the heart muscle, which ruptured into the pericardial sac and produced a pericarditis.—*Wien. Medizin. Presse.*, No. 5, 1892.

HERNIA, OPERABLE AND INOPERABLE.

Thos. H. Manley, in a paper on this subject, submitted at the late meeting of the American Medical Association, concluded as follows: Although, during the past fifteen or twenty years, very much has been written on hernial operations; much in America, but more in Europe, so far as can be learned from current literature, no one has yet made an attempt in a methodical manner, in any brochure of or treatise published, to systematically describe and classify those herniæ which are operable and those which are not. For the purpose, of at least in part, filling in this void, this essay is offered.

In epitomizing the subject and considering the question of treatment of hernia, in a general way, it may be said with something approaching definite certainty:

1. That, inasmuch as no operative techinique yet devised, or even can be, will always effectually remove the courses of any species of hernia; in consequence of this a permanent, enduring cure is quite out of the question, in certain cases.

2. The radical cure of hernia may be regarded as one of the most satisfactory operations in general surgery. The fact that the disease often relapses constitutes no valid objection against surgical intervention; for this is commonly the case in the major part of operations performed on the human body.

3. A radical operation for a non-strangulated hernia, which gives no serious inconvenience, is not a justifiable procedure and should not be encouraged, unless there are pressing reasons for it, as the presence of a neoplastic formation in the sac; or this latter is occupied by an ovary, or some other viscus.

4. Hernial operations should not be performed in extremes of age. In early life there is seldom pressing necessity for them. In very advanced age the risk, immediate or remote to life or death, involved by operation more than compensates for the prospective benefit.

5. Unless there are specially contra-indicating factors in given cases, inguinal hernia should always be treated by radical operation in women, which, with them is so often attended by a permanent cure.

6. As a rule, all operations on reducible or incarcerated herniæ are radically curative, though the disease commonly relapses; nevertheless, the immediate dangers of strangulation have been removed and the hernia has been placed in position to be more comfortably borne by a truss.

7. Every operation for strangulated vaginal or femoral hernia should always include such additional steps, as will effect thereafter an obliteration of the canal without undue pressure on the tubular structures passing through it.

8. Very large, old herniæ, in any of the abdominal regions are not operable, except in the event of strangulation, as their sudden return is often attended with mortal consequences.

HYPERÆSTHESIA OF THE CRANIAL BONES.

Benedikt (*Intern. klin. Rundschu,* No. 1, 1892) remarks on the importance of examining the cranial bones for undue sensitiveness, as a proceeding analogous to testing for spinal tenderness. He describes a form of caphalalgia in which pain and tenderness are confined to the cranial sutures. He has found this "suture neuralgia" in persons subjected to prolonged worry and overwork, in some nervous disorders such as Basedow's disease, and in persons at the age when the sutures are ossifying. He cites the case of an overworked youth, aged 19, in whom convulsions suddenly developed and quickly ended in death. Hæmorrhagic pachymeningitis was diagnosed, but the chief necroscopic discovery was acute synostosis of the cranial sutures, proceeding from within outwards. In a man, aged 51, affected with atrophy and paralysis of the left half of the tongue, paresis of the right labial muscles, formication in the right arm, and occasional speech troubles, Benedikt discovered great hyperæsthesia of the left half of the base of the skull, including the accessible portion of the orbital roof, and the left half of hard palate. Taken with the other symptoms he was inclined to consider this hyperæsthesia as a pathognomonic indication of bulbar affection. Unilateral hypersensitiveness of the cranial base is often present, he finds, in old standing migraine.—*Brit. Med. Jour.*

OBSTETRICS

THE CHOREA OF PREGNANCY.

In an article upon this subject (*International Medical Magazine*, July, 1892), Dr. Lloyd, of Philadelphia, gives the prognosis as follows: Very practical questions are involved in the prognosis both to the mother and the child. Some years ago an English obstetrician, Barnes, wrote a paper on all the cases of the chorea of pregnancy that he could find in medical literature. His statistics seem to prove that about seventeen out of fifty-six are fatal. I think that this is an over-estimate, for this reason: It has happened in the past that only the fatal or the severe cases have been reported. I have seen five cases of the chorea of pregnancy, none of which have been fatal. Milder cases are not apt to get into print. I think that, while the chorea of pregnancy is a grave disease, it is not as grave as Barnes's statistics seem to prove. Another question comes up—the prognosis in the case of the child. Statistics have also proved that some of these women go into premature labor, and that some of these children are still-born

or die shortly after birth, probably because of the premature labor or because of the mother's reduced condition. A very practical question which you will have to face is, whether or not you shall bring on premature labor or even abortion. Many of these cases of chorea in pregnancy certainly recover after labor, but a small proportion do not, and on that account it is difficult to advise when premature labor should be induced. When the woman's life and the babe's life are in jeopardy it is justifiable, even imperative, to act. I think that after seven months in some cases, the chances for the babe's life may be better if taken from the mother. Recollect, however, that women do not all recover after confinement, and that the child does not always live.

POST-PARTUM HÆMORRHAGE.

How to prevent this formidable complication of labor, and how to check it when once the flood-gates have burst open are problems of the greatest importance to every practitioner throughout the land. Although one reads a good deal of it in text-books on obstetrics, it is fortunately by no means common, at any rate in its severer forms. Many a practitioner with extensive experience of the lying-in room has never met with a fatal case, and the records of over 11,000 labors at one of the London hospitals show only one fatal instance of post-partum hæmorrhage. In cases of moderate severity almost any of the means usually resorted to will suffice to excite uterine contraction, and so put an end to a condition full of danger for the woman, and full of anxiety for the medical attendant. The question is really what can be done to goad into activity the typically inertia-stricken uterus. Shall we pack the uterine cavity full of gauze as a last resort, or shall we content ourselves with temporarily arresting the outpour by manual pressure? To pack the uterus tightly enough to exercise efficient pressure on its walls is a task which few would care to attempt, while the ever-present danger of introducing pathogenic organisms from without cannot be overlooked. We have a shrewd suspicion that the cases in which success has followed the more radical measures would have proved amenable to milder treatment if persevered in.—*Med. Press.*

ACTION OF HYDRASTIS CANADENSIS ON THE UTERUS IN THE PUERPERAL STATE.

Bordé (*Rif. Med.*, February 25th, 1892) gives the results of his experience with hydrastis and its preparations. As regards hydrochlorate of hydrastine, he finds that (1) it has no action on the physiological loss of blood during and immediately after labor; (2) it has no influence on the involution of the uterus during the puerperium; (3) it has very little influence on the lochia, its action, if any, being to cause (*a*) greater persistence of the red lochia, (*b*) delay in the expulsion of clots, (*c*) greater fætor of the lochia; (4) it does not assist the expulsion of clots and other bodies contained in the uterus. As regards the extract of hydrastine, he concludes from observations on twenty-five normal labors in which the drug was given in large doses during and for ten days after delivery that, if this drug has any action at all on the uterus in the puerperal state, it is to diminish the activity of its reaction and contraction, and therefore to increase both the loss of blood and the subsequent troubles. Finally, he gives it as his experience with the drug, in a few cases of non-puerperal uterine hæmorrhage, that it always failed.—*Brit. Med. Jour.*

GYNECOLOGY.

EXPERIENCES IN THE OPERATIVE TREATMENT OF RUPTURED TUBAL GESTATION.

A. Gusserow (*Berlin. klin. Wochensch.*, No. 22) relates briefly twenty cases which have come under his care, and enunciated his views regarding the course of tubal pregnancies, as follows:

(I) Rupture of the tubal sac which may be either a sudden bursting of the tube or it may follow the formation of a small opening in the wall through the destruction of the tissues by the growth of the chorionic villi. This form of rupture may lead to the following condition:—

(1.) Free hæmorrhage into the abdominal cavity always attended with a fatal result if not relieved by operation.

(2.) To slight free hæmorrhage which it is conjectured occurs in drops, becomes encapsulated and leads to secondary hæmatocele.

(3.) The hæmorrhage may occur be-

tween the folds of one of the broad ligaments, and lead to hæmatoma of the ligamentum lata.

(4.) The hæmorrhage may occur into the lower part of the peritoneal cavity, after this has been shut off by previous adhesions from the rest of the abdominal cavity forming what is known as primary hæmatocele.

II. The ovum through contraction of the tube may be expelled through the abdominal opening and the conditions described under 1, 2, and 4 may obtain.

III. The ovum *in situ* may undergo death through hæmorrhage into the decidua and form what is known as a "flesh mole" which (1) may shrivel and remain as a small hard swelling behind the uterus, or (2) may lead to the conditions described under I. from fresh hæmorrhages into the tubal canal.

Thirteen of his cases belonged to group I- and all ended in recovery excepting one. The remaining seven cases were done for secondary hæmorrhage occurring in hæmatocele. Theoretically he is in favor of doing a laparotomy at once in every case of extra-uterine pregnancy when the diagnosis is certain but this *proviso* does not frequently obtain, hence the majority of cases cannot be operated upon until after rupture.

DEATH FROM RETROFLEXED AND INCARCERATED UTERUS.

Treub (*Nederl. tijdschr. v. Verlosk en Gynäkol.*, Jahrg. iii., No. 3) reports a fatal case of incarcerated, pregnant uterus. The post-mortem revealed gangrene of the colon, followed by acute peritonitis. He has collected fifty cases of death from this cause, and in none of them except his own, was gangrene of the intestine a cause; 13 perished of uræmia, 11 of rupture of the bladder, 6 of sepsis, 10 of peritonitis followed cystitis, 3 of pyæmia, 2 of rupture of the peritoneum, and 5 of accidents accompanying an effort to replace the uterus. Gangrene of the intestine is, therefore, an unusual cause of death in this condition.

PEDIATRICS.

EXOPHTHALMOS IN AN INFANT.

Dr. Philipsen (*Annal d'Oculist*, December, 1891) saw an infant of ten days with a pronounced displacement of the right eye forward and downward. It had been noticed two days after birth. A smooth, rounded tumor could be made out within the orbit, fluctuating, and painless on pressure. Without treatment this disappeared gradually and the eye regained its natural place, and three months later showed no signs. The diagnosis was cephalæmatoma, developed either between the periosteum and the orbital vault and between the dura mater and the vault, and having penetrated into the orbit by a congenital communication.

DIPHTHERIA AND CROUP.

The science of bacteriology has already opened a floodway of light upon many obscure problems in the ætiology of disease; and evidence is not wanting as to the practical application of the information obtained from this source. While perhaps not yet absolutely proved, there is abundant testimony, clinical and otherwise, pointing to the identity of the two processes, diphtheria and croup. Partly in consequence of early teaching, partly because the evidence is not conclusive, there is still a minority that maintains the individuality of the two affections. One of the most conclusive clinical arguments of their identity is afforded by the fact that in some of the large Continental hospitals cases of croup and diphtheria are placed side by side in the same ward, and the cases of croup do not become infected; while it is not rare for diphtheria to develop in a family in which an apparent case of croup has been present.

The almost general acceptance of the dictum of identity is indicated by the tendency to treat cases of croup as though they were diphtheric, and the instructions of Boards of Health that cases of croup be reported. Fraenkel (*Deutsche medicin. Wochenschr.*, No. 24, 1892, p, 564) has added an opportune and valuable contribution to the controversy. The opportunity was afforded him of holding autopsies in four cases, all clinically typical instances of croup. In none were the subjective or objective evidences of pharyngeal involvement present. All presented hoarseness and marked difficulty in breathing. In two, tracheotomy was performed. The autopsies confirmed the freedom of the pharyngeal structures. In one case the membrane was situated below the glottis.

Examination of the membrane present in each case disclosed the presence of the bacillus of diphtheria described by Klebs and Loeffler, the identity of which was absolutely assured by its morphologic appearances, by its behavior in culture, and by its pathogenicity to animals. It is true that the number of cases reported is small, but the evidence adduced is positive and conclusive, and not to be controverted by any negative evidence.

Investigations by Middeldorpf and Goldman (*Deutsche medicin. Wochenschr.*, No. 24, p. 570) have disclosed the identity of the pathologic processes in croup and diphtheria. In both there occurs an intense inflammation of the mucous membrane, leading to destruction and desquamation of epithelium. Abundant exudation takes place, with subsequent coagulation and the formation of membrane.—*Medical News.*

THE ÆTIOLOGY OF APHTHOUS STOMATITIS.

Ollivier (*Revue Mensuelle des Maladies de l' Enfance*, 1892, No. 1, p. 11) adduces some new observations in support of the view that the milk of cows and goats suffering from aphthous fever is capable of producing an aphthous stomatitis in persons who drink it. He does not deny that aphthæ may result from a simple herpetic eruption or from a local irritation; but he insists that distinct manifestations follow the drinking of infected milk. This view was originally suggested in 1765, by Sagar, who observed an epidemic of the disease among the monks of a Franciscan convent, where the principal article of diet was milk derived from a herd of cows at the time affected with aphthous fever. The observations of other writers, which tend to further corroborate this view of thei-ætiology of the disease, are discussed in detail. Bacteriological studies by Fränkel have shown the presence of the staphylococcus pyogenes citreus of Passet and the staphylococcus of Rosenbach; but neither of these organisms has a specific importance. In man, and especially in the case of children, the disease is absolutely without danger. Demme has reported one fatal case, and Fränkel records three or four. Prophylactic measures are, therefore, important; and when several cases occur among a number of children fed upon milk from a common source of supply, the milk should be well boiled; or, better, perhaps, a new dairy should be sought.—*Amer. Jour. Med. Sci.*

HYGIENE.

RELATIVE VALUE OF GERMICIDAL CHEMICALS.

As the germ-destroying agents given below are the results, recently obtained (*Am. Drug.*) by the Health Department of New York City, they may be relied upon as accurate and conclusive. They rank in effectiveness as follows:

Corrosive sublimate, 64 grains to the gal.

Carbolic acid, 5 per cent. solution.

Bromine, 1 pound to 200 gals.

Permanganate of potash, 7¾ ounces to 200 gals.

Chloride of lime, 4 ounces to the gal.

Sulphate of iron, 1½ pounds to the gal.

Sulphate of zinc, 4 ounces to the gal.

Common salt, 2 ounces to the gal.

Two semi-officinal deodorant solutions are also spoken of—*Liquor Zinci et Ferri* for domestic use where iron is unobjectionable, and *Liquor Zinci et Aluminii Compositus* for disinfecting clothing, etc.

ROAST AND BAKED MEATS.

A writer in the *Lancet* says that the adoption of the closed range has to a great extent caused the abandonment of the method of roasting our meats before an open fire, and substituted therefor the process of baking in a close chamber or oven. The latter no doubt is the more convenient and economical method, but it may be questioned whether it is as wholesome. In baking the meat is, as it were, cooked in its own juices; the vapors exhaled from the warm meat are confined in the close oven and do not escape into the atmosphere, adding no doubt to both the flavor and richness of the food. At the same time the joint surrounded by this dense vapor does not yield its juices so freely as when roasted. Moreover the gravy from baked meat when cut, always yields more grease than does that from roast meat.

It is this retention of the volatile aroma and unctuous juices that render baked meat so popular, and no doubt with persons of strong stomachs it is not harmful;

but when digestion is weak it is undoubtedly injurious, and, when continued, its use aggravates or causes indigestion, and in many instances very considerable benefit has resulted from the physician's advice to the patient to have his meat roasted instead of baked.

Our knowledge at present regarding the respective digestibility of different fats is very imperfect; still the general and popular opinion is that the more oily fats are less digestible and more "bilious" than the solid, and it is these fluid fats which form the grease of cooked meats.

The author states that he does not wish to raise a panic with regard to the useful oven, but merely suggests that baking may in some instances be the unsuspected cause of indigestion, in which case a return to the roasting jack and the open fire would prove to be a step in the direction of a rightful cure.

MEDICAL CHEMISTRY.

BENZOATE OF BISMUTH.

Bismuth benzoate is claimed by Vibart (*Sem. Med.*) to be preferable for various reasons to the salicylate, the main objection to the latter being its uncertain composition and frequent contamination with free salicycle acid, whereby it becomes caustic in contact with the lining of the stomach. Bismuth benzoate may be prepared in the following manner: Mix together 100 grams of bismuth nitrate, 20 grams of glycerin and 60 grams of distilled water. To this add a hot solution consisting of 76 grams of sodium benzoate and 200 grams of water. The bismuth benzoate is precipitated as a white, insoluble powder of slightly metallic taste. It is decomposed in the organism, benzoic acid being found in the urine.

A SUBSTITUTE FOR GOULARD'S EXTRACT.

The action of magnesium acetate solution upon magnesium oxide in hydrating the latter and causing a considerable portion to dissolve, has been made use of in the manufacture of "*sinodor*" preparations as deodorizing agents. Magnesium acetate solutions also have the power of dissolving lead oxide, and this is the basis of a patent for the manufacture of "white lead." A solution containing 4 per cent. lead oxide is especially desired. It is made as follows: 187 gm. dilute acetic acid are diluted with water and saturated with magnesium carbonate free from chloride, and water added to make one kilo. After filtering this, the specific gravity should be about 1.0377, the solution containing 10 per cent. magnesium acetate; it is then heated in a water bath for one hour with 7 per cent. lead oxide, and by the addition of water the original weight (one kilo) restored; after standing 24 hours the specific gravity is again determined, a difference of 0.001 indicating 1 per cent. lead oxide; if the difference is greater than 0.004 the solution must be correspondingly diluted. From the finished preparation an efficient *lead water* can be made by the addition of 4 parts to 96 parts water.—Dr. Kubel, *Archiv. dér Pharm.*, 1892, 173,

NEWS AND MISCELLANY.

ADULTERATED IODOFORM GAUZE.

Surgeons who use this dressing will do well to have its efficacy tested. The "Pharmacie Centrale" of Paris, warns the profession against the use of a gauze which professes to contain 30 per cent. of iodoform, but really contains only 8 per cent., the difference in color being made up by a preparation of phenol.

THE AMERICAN ELECTRO THERAPEUTIC ASSOCIATION.

A very full program is announced for the coming meeting of the American Electro-Therapeutic Association which is to be held in New York, at the Academy of Medicine, 17 West 43d Street, October 4th, 5th and 6th.

There will be two interesting discussions one upon "The Relative Fœticidal Value of the Different Currents and their Application to Ectopic Gestation," to be discussed by many prominent gynecologists and electricians, and another upon "Cataphoresis and its Practical Application as a Therapeutic Measure."

Papers are announced by Drs. Geo. J. Engleman, Wellington Adams, and Geo. F. Hulbert, of St. Louis; Wm. F. Hutchinson, of Providence, R. I., Franklin H. Martin, of Chicago, Ill., A. Lapthorn Smith, of Montreal, Canada, R. J. Nunn, of Savannah Ga., Thomas W. Poole, of

Lindsay, Ontario, C. Eugene Riggs, of St. Paul, W. J. Herdman, of Ann Arbor, Mich., D. S. Campbell, of Detroit, Mich., G. Betton Massey, of Philadelphia, Henry D. Fry, of Washington, D. C., H. E. Hayd, of Buffalo, N. Y., J. H. Kellog, of Battle Creek, Mich., C. G. Cannaday, of Roanoke, Va., Ernest Wende, of Buffalo, N. Y., and Wm. J. Morton, Augustin H. Goelet, A. D. Rockwell, Landon Carter Gray, Robert Newman, Ephraim Cutter, Frederick Peterson, G. M. Hammond, F. Van Raitz, of N. Y., and many others. Dr. J. Mount Bleyer, will give an instructive lecture with demonstrations entitled, "The Phonograph and Microphonograph, the Principles Underlying them and their Uses in the Sciences."

In connection with the meeting, there will be an exhibition of modern medical electrical apparatus, all the prominent manufacturers being represented.

The social part of the program includes many pleasant surprises.

SLEEPLESSNESS.

Whether, as appears likely, sleeplessness is more characteristic of our own days than those of our predecessors, or that, in accordance with a scientific fashion, it is now more noticed, we certainly hear of its prevalence with somewhat startling frequency. The nostrums proposed for the cure of this disorder are numerous. Many, if not most of them—we do not for the moment speak of narcotic drugs—are empirical, and are cast upon the public intelligence without any conscious reference to causes actually at work upon the brain and other nervous tissues. It does not necessarily follow that they are valueless, and we should no more think of repudiating their ordinarily legitimate exercise than of refusing the occasional aid of such medicinal agents as may be safely trusted to discharge the same needful function. It is to be understood, however, that we would, wherever possible, avoid, and replace by simpler non-medicinal methods, even such occasional useful aid. This attitude is but rational, if we consider that the true object of treatment is never by choice merely palliative, but curative, and for cure there is needed the detection and removal of an active cause. The revelation of the causes of insomnia is, indeed, no simple matter. Thus much, however, we may say—namely, that just as the state of the brain in normal sleep implies a quiescent cerebral circulation somewhat reduced in volume, so in those whose nights are habitually restless we shall commonly find a condition of cerebral vascular tension. This, let it be noted, is not incompatible with general anæmia or with defective brain nutrition. There is, indeed, nothing so conducive to local vascular congestion as the constant exercise of a weakened organ. Mental worry thus acts upon the jaded brain, and we need not wonder, therefore, that it "murders" sleep. The true means of relief is as clear as it is often impossible. In such cases, however, and still more in others where adequate, or even more than adequate, nutrition is maintained, we find a simple and ready antidote in physical exercise. Muscular activity, in fact may be employed to balance nervous irritation. In it we provide a means of counter exhaustion. There is a transference of vascular excitement, and of tension, with corresponding relief at the site first affected. Further, the same process implies a stimulation of the general metamorphic energy and the removal from the tissues of irritant excretable products. This brings us to another cause of insomnia, particularly of that which we sometimes observe in the gouty and rheumatic. It is probably on the ground of removal of such superfluous substances that we must explain the salutary action of the traditional "night cap" of hot water, or the boiled onion, a stimulant of the kidney, at supper. Where mental over-activity or irritation has to do with insomnia, the influence of change—that is, of a change in thought—should have a trial. It is no doubt a blind groping after this remedy that induces some to read themselves asleep. Better in several ways is the practice introdnced by the German Kant, who spent some time before he retired for the night in cutting off by an effort of thought each mental occupation of the previous working hours. We might, however, multiply the stock of remedies without meeting all possible needs. The desirable course for any sleepless unfortunate to adopt is obviously not to resort to sedative drugs to allay his distress, but to seek the advice of his trusted medical attendant and its remedy in the discovery and the removal of its cause.—*Lancet.*

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co

Sulfonal=Bayer

induces sleep, free from narcosis, and sequelæ. It acts purely as a hypnotic and claims no analgic powers. Sulfonal is also of the highest value in the neuroses and is largely employed by neurologists. It is a safe remedy and its continuous use does not give rise to a drug habit. Sulfonal must be given according to directions. (*Supplied in ounces.*)

Salophen

is a new salicylo-phenolic derivative said to be so combined, chemically, as to constitute a safer and more effective remedy than either of its components, or any analagous preparation. The reports refer in the highest terms to its value in rheumatism and allied affections. Competent observers recommend it for extended trial. (*Supplied in ounces.*)

Europhen

is a complete substitute for iodoform and is a cicatrisant of special value in specific lesions, catarrhal and ulcerative diseases and all surgical conditions formerly treated by the latter preparation. It has five times the covering power of iodoform and forms an impervious coating over denuded tissues. Europhen has a faint, agreeable odor resembling that of saffron. (*Supplied in ounces.*)

Phenacetine=Bayer

continues to justify the high praise of physicians, and it may properly be considered as the best of the modern antipyretics and anodynes. In *la grippe,* rheumatism, migraine, neuralgia, etc., it is a prompt, safe and effective remedy. Phenacetine, unlike the secret mixtures announced as analgesics and antipyretics, is a true organic derivative. (*Supplied in ounces.*)

Aristol

is now widely used as an agreeable and effective dressing in all of the operations of major and minor surgery and in dentistry. It is invaluable in ulcerations of all kinds, and in burns, blisters and bed-sores. It adheres closely to mucous membranes and wound surfaces. (Aristol and "Europhen-Aristol," a combination of both remedies are supplied in ounces.)

Full Descriptive Pamphlets sent on application.

W H Schieffelin & Co New York

FRELIGH'S TABLETS,

(Cough and Constituent).

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{75}$ gr.), Atropiæ Sulph. ($\frac{1}{250}$ gr.), Codeiæ ($\frac{1}{25}$ gr.), Antimony Tart. $\frac{1}{75}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{75}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

Clinical Lectures.

THE DIFFICULTIES AND DANGERS WHICH MAY ARISE FROM INDISCRIMINATE ATTEMPTS AT THE REDUCTION OF STRANGULATED HERNIÆ BY MANIPULATION.

By WILLIAM H. BENNETT, F. R. C. S. Eng.,

SURGEON TO ST. GEORGE'S HOSPITAL, LONDON.

Gentlemen:—It is, I assume, a matter of common knowledge that many methods of treatment in themselves excellent, and when properly used of much practical utility, may under certain conditions be not only harmful but perhaps disastrous, especially if applied without discretion by any person who does not possess the knowledge or skill requisite for their safe employment. The means available for the reduction of a strangulated hernia without operation form no exception to this rule, and by an unusual chance there are now under my care two patients lying in the Harris ward, separated from each other by a single bed only, whose cases illustrate this fact in a remarkable way.

Case 1. *Strangulated inguinal hernia*; *prolonged unsuccessful taxis*; *herniotomy*; *gut found partially lacerated*; *suture of bowel; radical cure; recovery*.—W. F——, a man aged twenty-seven, was admitted on Nov. 18th, 1891. In the previous April he found for the first time that he was ruptured on the right side. The hernia was always reducible, and a truss was continually worn. On the morning of the day before the patient came into the hospital the spring of the truss broke and he was therefore obliged to work without it. The hernia soon came down, and he was unable to reduce it. Vomiting thereupon set in, and during the night occurred many times. A few hours before his admission an attempt, lasting about a quarter of an hour, was made to reduce the hernia by manipulation, but without success, the the patient suffering great pain, especially during the latter part of the attempt. The bowels acted regularly up to the morning of the 16th. On admission the man had an anxious look and was evidently in very acute pain. There was occasional retching, by which a small quantity of sour-smelling gastric contents was brought up. The tongue was white, but moist; the pulse 100 and fairly full. In the right side of scrotum and running up to the groin was a large, acutely painful and tender swelling, very tense resonant and entirely without impulse. There was much pain about the umbilical region and also some tenderness over the hypogastrium, but no distention. Having regard to the prolonged taxis to which the hernia had already been subjected, no further attempt at reduction by manipulation was made, herniotomy being at once performed. Upon opening the sac several ounces of reddish fluid, containing air, escaped. A large knuckle of greatly distended gut then came into view, deeply congested and greatly glued to the lower part of the sac by very recent peritonitis. On freely exposing this gut, by laying open the sac from end to end, there was found over its most prominent part (i. e., at the anterior aspect of its lower end) a longitudinal laceration involving the peritoneum for about an inch; over half its length this rent passed through the subjacent muscular coat, from the opening in which the mucous membrane protruded, and seemed on the point of bursting. The stricture, which was at

*Delivered in St. George's Hospital Medical School, and published in the *Lancet*.

the inner ring and extremely tight, was then very freely divided with the hope that the tension in the gut would be thus sufficiently modified to allow of the wound in the bowel walls being sutured. This, however. was found to be impracticable, as the stitches immediately cut their way out, the tension not being sufficiently relieved spontaneously. It was at the same time clear that any attempt to reduce the tension by pressing the air contained in the bowel back into the abdomen would result in the rupture of the protuding mucous membrane, which I was particularly anxious to avoid for reasons to be presently discussed. I therefore selected the healthiest available spot on the bowel, and there punctured it with an exploring trocar, afterwards emptying the knuckle of gut of the contents, which consisted principally of altered blood, through the cannula. This having been done the gut naturally collapsed. The wound in its walls was then brought together with perfect ease and safety by means of five Lembert sutures of silk. A single suture of the same kind having been passed across the small peritoneal wound made by the trocar, the bowel was finally thoroughly cleansed and returned into the abdomen. The neck of the sac was then isolated, ligatured, and severed from the scrotal portion; the pillars of the ring were closed by kangaroo tendon sutures, a drainage-tube inserted, and the superficial wound united with silkworm gut. On the 20th four loose motions containing altered blood were passed. The bowels acted daily after this, and by Dec. 18th the patient was walking about the ward apparently in perfect health. In fact, he was practically well by Dec. 4th, but being very apprehensive about himself he was allowed to remain in bed longer than was really necessary. In addition to the points specially relating to the main subject of the present lecture, this case affords a good illustration of the successful treatment of cases of the kind by a method to which I wish to call particular attention. In all instances of strangulated hernia in which the laceration of the bowel does not involve the whole thickness of its walls, so that the intestinal canal is not opened up, the gut as the result of the strangulation is of course generally distended. In attempting to bring together the edges of the wound under these circumstances difficulty generally arises in consequence of the sutures cutting their way so readily through the peritoneum, that sufficient traction cannot be made upon them to effect the closure of the laceration with any safety. This tendency on the part of the stitches to cut their way out is due partly to the unyielding tension of the bowel and partly to the softening of its coats from pathological changes. Not only therefore is very little pressure required under such circumstances to increase the rent in the peritoneum, but when the tear involves the whole thickness of the muscular coat the mucous membrane bulges through the wound, and extremely slight force only is necessary to cause the protuding portion to give way, thus converting an incomplete laceration into a wound opening up the intestinal canal.

In cases of this sort it is sometimes also found that even after free division of the stricture no sufficient alteration in the tension occurs until digital pressure is used, which may be quite sufficient to burst the stretched and protruding mucous membrane—an accident which it is most important to avoid if possible, not only because it must of necessity allow the bowel contents to escape over the wound, but also because the protruding membrane is usually so thin and injured that if it is damaged further by laceration, incision or puncture, ulceration, and perhaps sloughing, is prone to occur later on, and give rise to trouble which may possibly be serious. In order to diminish the tension of the bowel and to allow of its shrinking of its own accord and without any necessity for inflicting further injury upon the protruding mucous membrane, I adopt and confidently recommend the following plan, which, it will be noticed, was used in this case.

The stricture having been freely divided, and the distended knuckle of gut carefully cleansed, an exploring trocar is passed into the bowel through the portion of its walls which appears most healthy (i. e., at a point which is certain to be somewhat remote from the laceration). The contents of the gut, consisting generally for the most part of altered blood, pass out easily through the cannula into a suitable receptacle, and are thus conducted quite away from the peritoneum, which therefore remains entirely unsoiled, as the muscular coat at the point of puncture clings so closely to the cannula that no leak takes

place. On the other hand, if the puncture be made in the protruding mucous membrane, leakage is certain, and soiling of the whole rent occurs, in addition to the injury inflicted by the puncture on the damaged structures. The collapse of the gut which follows spontaneously makes the approximation of the peritoneal surface over the laceration perfectly easy and safe, no matter how softened the intestinal walls may be. The gut may then be returned without hesitation, after it has been finally cleansed and a peritoneum at the seat of the puncture. This last detail is perhaps hardly necessary, but it is a source of additional safety during the return of the bowel, and adds nothing material to the length of the operation. The method here described of relieving tension in damaged or partially lacerated bowel by puncture through the healthier parts rather than through those which are most injured has, so far as I know, not been previously insisted upon but I am sure it is worthy of adoption.

Case 2. *Inguinal hernia with large hydrocele; attemped reduction by patient; rupture of wall of hydrocele, which was thus converted into a hæmatocele.*—W. B ——, a laborer aged fifty-three, was admitted into Harris ward on Nov. 21st, 1891, with the following history. Three years previously he commenced wearing a truss, as he was told he had a rupture; and about eighteen months later he noticed some swelling of the scrotum which, upon applying to the Truss Society, he was told was not a hernia. On the day before he came to the hospital he felt some pain about the groin and noticed more swelling there than he had previously seen. Thereupon, thinking it was the hernia which had come down, he attemped to put it back by seizing the whole scrotal tumor in his hands and using considerable force. No immediate alteration was produced in the swelling, but acute pain followed directly, and in a few hours the whole scrotum became almost black. The pain gradually decreased, but much tenderness followed, on account of which he applied for treatment. On admission the patient was a big, strong-looking man. The left side of the scrotum was much discolored and distended by an oval swelling, very tense, tender, and non-translucent. Its upper end was quite free from the abdominal ring, which was large, and through it a hernia came down when the patient coughed. The bruising slowly disappeared, and the swelling decreased a little in size after rest in bed. On Dec. 17th, I laid open the scrotal tumor, letting out a quantity of hydrocele fluid and altered blood. On examining the walls of the cyst there was found at the upper and inner part a large rent, admitting the ends of three fingers, which passed into a considerable space beneath the scrotal integuments. The parts about this were matted together with recent inflammatory material and the walls of the hæmatocele were covered with new lymph. The hernia was not exposed in the operation, as it was thought wiser, considering the inflamed condition of the tissues, to postpone its radical cure, which the patient was anxious to have performed, until a subsequent date. The patient naturally made an uninterrupted recovery.

The main point of individual interest in this case is the fact that the injury was self-inflicted. Although the lesion produced here by the patient's manipulation was not a serious one it may sometimes be so. I have myself had an opportunity of seeing an instance in which taxis applied by the patient resulted in a small rent in the gut through which some fœcal material had escaped into the sac. It is true that the gut at the seat of injury had obviously been adherent and the laceration had resulted from the tearing away of the adhesion by the force applied; the fact, however, is significant that laceration of the bowel itself was produced by no more violent manipulation than that applied by the patient himself, who was perfectly accustomed to reduce his rupture.

The main possible disasters which may immediately follow upon attempts at the reduction of herniæ by taxis may be summarised as follows:—(1) Bruising the bowel; (2) rupture of the bowel wall; complete and incomplete: (3) laceration of adhesions; (4) rupture of the sac; (5) hæmatocele (in cases complicated with hydrocele); (6) hæmatoma of scrotum and surrounding parts; (7) reduction of the whole hernia with the sac (reduction *en bloc*).

1. *Bruising of the bowel.*—Some bruising, as shown by subperitoneal extravasation, of large or small extent, about the herniated bowel will be found in the majority of cases which have been submitted

to taxis unless extreme gentleness only has been used. The extent and severity will naturally depend, for the most part upon the amount and direction of the force applied and to a considerable degree upon the condition of the gut, which bruises more readily when greatly distended, especially in neglected cases which have been allowed to continue for a long period without treatment. It is interesting to note that bruising of the bowel, if in any way extensive, although without any apparent breach of surface on the peritoneal aspect, is almost invariably associated with bleeding into the intestinal canal, a fact conclusively demonstrated in many cases by the characteristic appearances of the first motion passed after the relief of the stricture, which nearly always contains altered blood. It may, in fact, be accepted without reserve that attempts at reduction by manipulation produce some bruising of the bowel in the great majority of cases of strangulated hernia. At the same time it may be fairly admitted that as a rule, unless great carelessness has been used, no permanent harm results. It is nevertheless necessary to insist on the occurrence of injury of the kind in order to give weight to the fact that attempts at reduction by manipulation are liable at times to cause injury. Taxis therefore should not be regarded, as it seems to be by some people, as a plan of treatment which if it fails to reduce the rupture, at least can do no harm. This last remark must not be taken to imply any objection to the proper practice of this method, but merely as a warning against its use carelessly and without due regard to possible evils which may under certain conditions result.

2. *Laceration of the bowel.*—This may of course involve the whole thickness of the intestinal wall or only one or more of its coats; the former is naturally the most serious since it allows of the escape of fæces into the sac. The latter condition may vary in degree from an almost imperceptible crack in the peritoneum to a laceration in the peritoneal and muscular coats inches in length, in which case the mucous coat protrudes, hernia-like, through the opening in the muscular wall. Whether the laceration is partial or complete the treatment is identical. The edges of the wound must be brought together with Lembert sutures, care being taken that the end stitches—if the lesion is of any extent—are placed a short distance beyond the extremities of the rent. When the gut is too tense to allow of approximation of the peritoneal surfaces it should, if necessary, be emptied in the way I have described in the first of the cases which form the text of this lecture. However small the crack in the peritoneum is, even if it be hardly perceptible to the eye, a single suture should be passed across it. If the condition of the patient in case of partial laceration is so desperate that the delay entailed by the suturing process is not justifiable the gut should be cleansed and returned into the abdomen, an unperforated drainage tube of large calibre being left lying in the canal in the way I have recommended in a lecture published in *The Lancet* in 1890.

A point of great interest to which sufficient attention has not, I think, of late been paid arises here with reference to the situation at which laceration from injury occurs in these cases. There appears to be an idea, which is traditional and supported by the teaching of the schools now that the tear produced by injury in the gut of a strangulated hernia takes place *at the seat of stricture* in consequence of the way in which the sharp edges of the constricting tissues as it were, cut into the distended bowel when pressure is exerted upon it.

Now I have seen several cases myself in which a rent in the gut was undoubtedly produced by taxis, and in two of these the lesion *was not at the point of constriction but on the prominent bulging and most distended portion of the bowel.* Both of these cases were recent, and in each the rent was in the long axis of the gut. The same result followed in some experiments made by me on the cadaver, artificial strangulation in two cases of old herniæ having been produced by inflating the bowel from the abdomen and forming a stricture by ligaturing the neck of the sac together with its contents. The hernia was in one instance then violently crushed and in the other struck with a stick; in both the laceration occurred on the prominent part of the strangulated knuckle and in the long axis of the gut. On consideration, this result, so far as the situation of the injury is concerned, is I think precisely what should be expected in recent cases, for in such the rent begins in the peritoneum, which under pressure

naturally gives way at the weakest point (that is to say, where it is most thinned and stretched by distension). A sudden blow, therefore, or prolonged hard pressure would as a matter of course lacerate the peritoneum in the part most stretched and thin— i. e., over the end of the distended knuckle rather than at the seat of constriction, where not only is it unstretched, but where it is actually supported by the surrounding parts.

In cases far advanced and neglected the state of affairs is altogether different, because in them the gut at the seat of stricture is indented by the edge of the constricting tissues, partially eaten through by ulceration from within, or perhaps grangrenous and on the point of giving way. Then the weakest point is at the strictured part, and very little force may be necessary to complete the perforation which has already commenced. It is, I presume, in connection with cases of this latter kind that the traditional teaching has fostered, for in recent cases of strangulation it certainly does not apply.

3. *Ruptures of adhesions in the sac.*— The tearing of recent adhesions during attempts at reduction by manipulation need not have any serious result, but free hæmorrhage into the sac may thus be produced so as to fill it completely with blood, although no serious lesion may be apparent. In old irreducible herniæ, in which band-like adhesions sometimes exist between the bowel and the sac wall or between different parts of the bowel itself, no harmful results need follow if the adhesions themselves give way, but if, as may happen, an adhesion brings away some of the intestinal peritoneum with it, a partial laceration of the gut results, which is, if at all extensive, a serious condition, especially if the case has been neglected and operation long deferred.

4. *Rupture of the sac.*—This, although a recognized injury and classed as one of the modifications of the reduction *en masse*, must be a very rare sequence of taxis, as the amount of force required to tear the sac is very great and would hardly be intentionally applied. Bruising of the sac is, however, common and I have seen a portion of its wall torn away with an omental adhesion; this, however, is not a rupture in the sense under discussion— i. e., a splitting of the sac wall from sudden or gradual pressure. In the post-mortem room I have not been able in artifically strangulated herniæ to rupture the sac without also bursting the gut. Rupture of the sac is therefore probably too rare to be other than a curiosity; indeed Sir Astley Cooper, after his large experience, says that it "scarcely ever" occurs from any cause. Formerly spontaneous rupture of the sac was also a recognized condition, but actual evidence of its existence seems wanting, or at all events is not convincing.

5. *Hæmatocele.*—A good example of this accident is afforded by Case 2, described in this lecture. After what I have said concerning the difficulty in causing rupture of a hernial sac it may at first sight seem strange that the sac of a hydrocele should give way so easily. There is nothing inconsistent, however, in this, for it must be borne in mind that the sacs of hydrocele sometimes undergo pathological changes which result in softening and thinning, so that they become weak in parts.

6. *Hæmatoma from rupture of a large vein or veins outside the sac.*—Enormous blood extravasation may be thus produced and occasionally upon the application of comparatively slight force, especially in elderly people. I once had an opportunity of seeing a large blood swelling involving the scrotum and groin, which were nearly black from discoloration, said to have followed upon nothing more violent than manipulation necessary for the adjustment of a truss to an easy reducible hernia in a subject nearly eighty years old.

7. *Reduction "en bloc"—i. e., the reduction of the sac, together with its contents, the strangulation being therefore unrelieved.*—The only point to which I need here call attention in this respect is the singularly small amount of force which sometimes seems necessary to produce this accident. I have personally seen only one case, and that was not in my own practice. The hernial tumor seemed to disappear almost the moment the hand was laid upon it and certainly before there was time for the application of any methodical violence. So much was this the fact that I cannot help feeling that there must be in such a case some kind of spontaneous action from above which contributes to the reduction. Is it possible that extreme irregular spasmodic attempts at peristalsis may act in this way?

It is only fitting that such an ominous list of casualties, which are not only possible, but actually occur in practice as the result of the use of taxis, should be followed by some indication as to when and how the reduction of an irreducible hernia by manipulation may be attempted without risk. The relative safety of this plan of treatment is dependent on three conditions: (1) The manner in which the taxis is applied; (2) the period during which the manipulation is persisted in; and (3) the state of the hernia.

1. *The mode of applying taxis.*—This may apper such a purely elementary point as to render its consideration hardly justifiable outside the pages of a student's text book. It is nevertheless true that practitioners, otherwise intelligent and trustworthy, do at times manipulate a hernia in the manner best calculated to cause injury to the contents of the sac, whilst it affords the least possible chance of effecting reduction. I do not propose to occupy time now with a description of the method by which the taxis may be applied safely and with a fair prospect of success, as it can be more usefully learnt from practical demonstration at the bedside, but some of the details of the process are so important and essential that they require a passing notice. The details referred to are as follows: (*a*) All manipulations should be conducted only with thoroughly warm hands; (*b*) the neck of the hernia should be firmly supported by one hand whilst the other manipulates the body of the tumor. (*c*) In using the fingers all pressure from the finger-ends should be made by *the front of the digital pad and never by the actual tips.* (*d*) The pressure necessary in the manipulations should be gentle, firm and regular, not forcible, unsteady and spasmodic. The necessity for warm hands, for the support afforded to the neck of the hernia, and for the avoidance of the use of the actual finger tips, is, I cannot help feeling, not so universally acknowledged as it certainly should be, for I have more than once seen attempts made at the reduction of a rupture by grasping the body of the tumor with hands almost blue with cold, the neck of the hernia being left entirely unsupported, and then with a punching and rolling movement, during which the finger tips have been deeply pressed into the parts, the force has been gradually increased until further persistence in the attempt has been rendered impracticable by the protests of the patient. Where injury is possible it is from some faulty plan as this that it is most likely to result. The cold hands excite every resistance in the way of muscular action; the want of support to the neck of the hernia makes its reduction very unlikely by allowing the gut to bulge over the margins of the constricting ring, and, beyond this, in neglected or longstanding cases when the bowel has commenced to ulcerate from within, the pressure of the sharp edges of the stricture acts at a great advantage in further injuring and perhaps bursting the thinned and weakened intestinal walls. Finally the sharply indenting finger tips are admirably adapted for causing an unnecessary amount of bruising and possibly laceration of the gut.

2. *The time which should be occupied in taxis.*—Judging from my own experience, and from what I have seen in the practice of others, five minutes should be taken as the outside limit during which manipulation of a hernia in cases of apparent strangulation or when impulse on coughing is absent may be with safety persisted in, no matter how gently it is applied. In unstrangulated cases the same time should always be considered as sufficient, for, although no actual harm need result, if the time be extended it may very easily produce it; moreover, if success is not attained by the end of five minutes it is very unlikely to result at all, and further attemps are practically useless.

3. *The condition of the hernia.*—When properly applied and with the precautions just mentioned taxis may be used with safety—(*a*) in all cases in which the true hernia impulse is present, provided always that there is neither any marked tenderness nor inflammation in the sac or its contents, when its employment would of course be entirely negatived; (*b*) in very recent cases of strangulation where the tension is not extreme. This latter is a recognized principle and is therefore worthy of respect, but I very much doubt whether it is possible, excepting perhaps in infants, to reduce by manipulation any rupture in which the hernia impulse is not present. For myself at least I must admit that I have never been able to return with any resonable application of force a hernia in which I could detect no impulse. This impulse, it is true may have some-

times been slight, but it was present all the same in the cases where reduction was possible, although it must be admitted that I could not always demonstrate it to my house surgeons, in the hospital patients. A large distended hernia universally resonant should be treated with more than usual gentleness, for in such cases the bowel is far more liable to injury than in any other kind, especially if adhesions happen to exist in the sac. Hernial tumors dull on percussion, with omental or fluid contents, may be manipulated with greater freedom without risk of damage being done, but in these reductions is entirely out of the question in the absence of impulse, the utility therefore of persistence in the attempt at all under these circumstances is not plain. Every case of apparently strangulated hernia must necessarily be treated upon its individual merits, but, for my own part, I am sure that, as a general principle, it is better in herniæ which are obviously strangulated and entirely without impulse to perform herniotomy at once rather than make attempts at reduction by manipulation, because I have no doubt whatever that early herniotomy in fairly competent hands is infinitely less hazardous than an unwise persistence in fruitless attempts at reduction by taxis. If due regard be paid to the patient's welfare, one thing at least is certain—viz., that a strangulated hernia which has once been subjected to taxis should be operated upon at once, and no further manipulations used until after the tumor has been explored and the structure freely divided.

It must not be imagined that all risk of lacerating the bowel during attempts at its reduction necessarily ends after the sac has been laid open in herniotomy, or indeed in every case after the stricture has been divided, for, although to the best of my knowledge the accident has not occurred under these circumstances in my practice, I have been present at an operation in which a surgeon of experience certainly did produce a laceration of the peritoneal coat of the bowel, whilst attempting to reduce it after the division of the stricture which obviously gave rise to the strangulation. This difficulty sometimes experienced in reducing the hernia after the stricture has been cut is undoubtedly as often as not due to the division being not sufficiently free, the little nick so commonly recommended being too slight for securing the necessary relaxation of the constricting band. I am sure, from my own observation that harm is more often likely to arise from too slight a division of the stricture than from one which is too free. Free division of the parts about the neck of the hernia as a rule entirely obviates any chance of injury to the gut, whilst the possible anatomical dangers entailed in this free incision have been, I have no hesitation in saying, unduly exaggerated.

Although I make a practice of dividing the stricture freely, I have never had the slightest cause to regret it, and certainly have never seen any hæmorrhage which has given the least anxiety under the circumstances. The only case in which I had any trouble whatever on account of bleeding after herniotomy was a strangulated umbilical hernia, in which alarming hæmorrhage took place into the abdominal cavity from a torn omental vein. This vessel was almost certainly burst by the force which was necessary for the return of the hernia through a ring which had been only slightly divided; had the division been altogether more free the hernia could have been reduced without any force and the vessel would, I believe, have undoubtedly have remained intact.

I now come to a point which is especially interesting in connection with a further difficulty which occasionally arises in the reduction of a hernia, even after the stricture has been freely divided. At first sight it is a singular fact that any difficulty should occur at all under these conditions, still it is quite certain that it is sometimes met with. For instance, in a case of inguinal-hernia, under my own care I was unable, after repeated division of the stricture, to reduce the intestine, although on passing the finger, as is my habit, through the canal into the abdominal cavity, I could feel nothing in any way constricting the bowel, The only noticeable thing to be felt was a loose membranous fold which, springing from the outer wall of the canal, lay quite flaccid upon the gut, and alllowed my finger to pass by it with perfect ease. Whilst I was attempting to return the bowel, the end of one finger being placed on it just below this fold, I noticed that as the gut was pushed against the flaccid flap the latter seemed to grip the bowel after the manner of a sling. I therefore divided

the fold, and then returned the hernia without the least trouble. Here, then, the obstacle to reduction was clearly this loose sling-like fold. The existence of membranous flaps like this and the manner in which they sometimes resist the return of the gut in operation for strangulated-hernia have not of late received the attention they merit. Bands and flaps of this kind, which are not very rare, should invariably be divided whether they seem to compress the bowel or not, for if they do not actually prevent reduction it will be much more easily effected after their division. The history and mode of formation of these interesting folds may be conveniently reserved for consideration in another lecture.

CHOLEDOCHOTOMY.

Prof. Küster reports the case of a woman aged 49, who had suffered for two years from attacks of violent colicky pains in the abdomen, recurring at intervals of four to six weeks and followed by jaundice. Gall-stones had been frequently found in the fæces. The patient was much exhausted and emaciated. Laparotomy was performed, an incision, ten cm. in length being made parallel with and below the border of the ribs. The large intestine was connected with the lower border of the liver and the gall-bladder by firm adhesions which were slowly separated. The gall-bladder was empty, but the common bile-duct contained two calculi, which were extracted through an incision two cm. long. The wound in the duct was closed by catgut sutures snd a continuous silk suture. A tampon of iodoform-gauze was inserted and the greater part of the abdominal wound sutured. Five days after operation the tampon was removed, a fistula being left, which later gave rise to a severe hæmorrhage, necessitating the reopening of the entire abdominal wound. The fistulous track was curetted, cauterized and tamponed, and the patient now made a rapid recovery, the jaundice disappearing completely. The author recommends choledochotomy in all cases of calculi in the common duct, where the latter is accessible and the stone can be felt. The operation has been performed seven times (inclusive of the author's cases) with only one death.—*Archiv. f. Klin. Chirurg.*, *Bd.* 43, *Hft.* 1, 1892.

Communications.

DISEASE OF THE KNEE-JOINT IN ITS CONVALESCENCE.

By T. M. LUDLOW CHRYSTIE, M. D.,
NEW YORK CITY.

For pathological reasons disease of the knee-joint has been divided into stages, generally three, in order to indicate its progress from the invasion to the destruction of the articular structure. But after appropriate treatment there is a regressive stage, and, finally, a convalescent stage. Failure to pass a patient through this latter condition properly is the cause of frequent recurrence of the inflammation and may on this account be mistaken for a tuberculous or fungoid affection, or due to a loose, floating cartilage; it is then condemned as a hopeless case offering excision or amputation as the only remedy. Bony ankylosis of the knee-joint from disease, treatment, or excision, is rare, difficult to obtain, unnecessary and undesirable. Fibrous ankylosis—whatever that condition may be—leaves the joint stiff but too unsteady for utility; at the same time it can be taken advantage of in restoring to the joint its function, that is, the mobility of a ginglymoid articulation, by encouraging voluntary muscular action while protection from undue force or use is provided.

Let the healthy lower extremity be supported by the surgeon placing one hand under the lower third of the thigh, and the other hand under the lower third of the leg. The patient is then asked to rest the weight of the limb in the doctor's hands—the muscles to be thus relaxed or devitalized—to use a term of Delsarte. Let there then be made a very slight, quick, lateral movement of the lower third of the leg. There will be felt or heard a click or bump at the knee-joint. Now, after a period of rest from use, enforced by the treatment or in the course of the disease, the muscles of the knee-joint are in this devitalized condition, and any attempt to use the knee-joint in walking or standing exposes it to a succession of injuries of this character. These either sooner or later of themselves produce a phlegmasia of the knee-joint, or maintain a condition which needs only

a slight fall or twist to accomplish it. If a so-treated patient can walk at all, and he does so with the knees exposed to view, the lateral jerk of the knee can be detected by comparing the action of the sound limb with its affected mate tho' the patient may be entirely ignorant of such effect.

The following case serves to illustrate the effect of this lateral inward movement: Patrick O'Connell, æt. 19, employed as orderly at the Ninety-ninth Street Reception Hospital (Department of Charities and Correction, New York City) was disabled every few months by synovitis of the left knee and was on that account brought to me in August, 1881, by one of the surgical staff. His duties required him to be active upon his feet. He had not received any injury, and there was no assignable cause for the recurrence of these attacks of synovitis. They yielded to treatment, and on recovery he could go about as usual. His health was good. He had a tall, spare, muscular, well-made form and a symmetrical gait stepping firmly on both feet. The appearance and function of the knee-joint were good in sitting and standing postures; but in searching further I had him strip, and, placing my hands on the crest of either ilium, discovered a want of symmetry in the length of the lower extremities, the left being 1⅞″ shorter than the right, unsuspected by the patient or those seeing him. When attending school some years previous however, he remembers being chided by the master, because, when sitting in class with other boys he did not place his knees on line. He never knew it was because there was a difference in the length of his legs. On having him walk across the room several times, a quick, lateral inward movement of the left knee at each step could be detected. The force or impact from bringing the foot 1⅞″ to reach the ground was received on the knee in a lateral direction and was an ever-present source of traumatism, particularly when his duties as hospital orderly required him to move about quickly in many directions. As the non-symmetry of limbs was a product of a too slow growth of the left extremity or a too rapid growth of the right (neither from any morbid process), the change from equal to unequal lengths of lower extremities was so gradual that the patient accommodated his body to a symmetrical gait without noticing the lateral jerk at the knee. This disappeared on the addition of a high cork shoe, and at the last report three years afterwards, there had been no further trouble.

The anatomical structure of the lower extremities can here be used in explanation of this behavior of the knee. The heads of the two femora are separated by the width of the pelvis, and the top of their shafts are placed still further apart by their necks. If the bones of the lower extremity were parallel to the median line of the body from the hip-bone to the feet, the knees and feet would be too far apart for comfort and appearance; our locomotion would resemble the waddle of a duck, though in an architectural point of view the construction would be good for the purpose of bearing superincumbent weight. The oblique direction of the femora gives the desired closeness and parallelism of the legs at and below the knees, and to make up for the want of steadiness from change of direction, large, strong muscles are provided to maintain the hinge-like function—diarthrosis-ginglymus—of the knee-joints. The thigh is consequently the most muscular part of the body, and women have larger thighs than men because of their wider pelvis. Now, in this oblique direction of the femora we have a predisposing cause for traumatism in a previously damaged knee, when its muscles and ligaments—which form the bolt for its hinge-like function—are devitalized and only loosely hold their joint, tho' the extent of motion may be limited to a very small arc.

There is another muscular condition to be considered in knee-joint convalescence, the inability of one set of muscles to let go in response to the active contraction of their antagonistic set. In whatever position, or degree of flexion or extension, the knee-joint is left after the disease, there is an arc of motion beyond which the joint cannot move. It may be a fraction of a degree or 20 or 30 degrees in extent. The muscles will not "let go" beyond this limit. Eventually they become in a state of contracture adapted to this arc, which acts adversely upon the articular cavity. The non-use of the joint has prevented the necessary extent of synovial secretion and parts of the articular surfaces are brought in contact when not in a proper condition. The patient does not complain of pain, but dreads to have the knee

reach that limit of motion, and may not allow any motion for fear that limit may be reached.

The synovial membrane is here the largest and most extensive in the body. In the interior of the joint are the posterior crucial ligaments, which are blended with or inserted into the inter-articular cartilages, and are surrounded by the synovial sac. When the movement of extension is performed beyond or up to the normal or the acquired limit, there is a strain upon these ligaments and injury done the connecting synovial membrane. A synovial pouch of this membrane lies under the tendon of the quadriceps-extensor muscle, as it passes upwards from the patella, and is held in place by the subcruræus muscle. This pouch is unduly compressed on flexion of the knee-joint, if the extensor muscle does not relax in unison with that motion. The membrane extends laterally under the vasti muscles, and is secured to the inter-condyloid notch by a prolongation of itself, the ligamentum mucosum. It is so intimately blended with the tendons, ligaments, and cartilages of the knee-joint, that if not in a perfect condition to perform its functions, it cannot but be injuriously affected if an unevenly distributed pressure is placed upon any portion of it by mechanical unsteadiness of the joint in any direction or by unbalanced muscular action. And yet the function of this membrane, the secretion of synovial fluid, cannot be acquired, except as the result of some use and motion of the joint.

In applying therapeutic measures at the beginning of treatment, in all probability the first and principal one will be *rest from use*, enforced at once and complete. But on the arrest of inflammation, we desire to procure *rest from disuse*, and often erroneously apply that at once and complete too. To continue rest from use after the inflammatory condition has gone, keeps up an impairment of nutrition, which will as surely destroy the joint as does the disease; but to *at once* institute the use of the joint without giving some definite protection as to the extent of this use, while the nutrition of the joint gradually furnishes its structures with vitality to resume their functions, is equally pernicious.

A patient having the knee-joint presenting only symptoms of a sub-acute inflammation is placed on his feet with crutches arranged to receive the impact of the body, but not to take its entire weight from the limb; the foot is allowed to rest upon the floor with a sense of being protected from having too much weight thrown upon it, and though there may be added a height of not more than one inch to the shoe of the sound limb, it is done only to remove from the affected limb the feeling of a superincumbent weight beyond its capacity and to lessen the amount of muscular effort in lifting the limb; but in no sense to make it pendent as is so often and injuriously done. This height of sole should be gradually lessened, as the joint gains strength, and finally removed. But a more precise protection is often needed, and apparatus on the following plan should be provided: The weight of the body should come upon an ischiatic strap in the same manner as stated in reference to the crutches. It is part of the treatment that the joint is benefited by receiving a portion of its share of the superincumbent weight of the body. This is removed as the necessity for its use ceases, and the rest of the apparatus to which it is attached continued as will now be explained. There should be a joint at the knee which can be locked immovably at any desired angle, or to be free at the will of the patient. The construction of this joint should not permit lateral motion, and yet move easily and smoothly. The hinge-like surfaces are best made parallel and smooth by being cut from a solid bar of steel by the revolving cutter of a milling machine. Much of the lateral steadiness depends upon the bolt having a sufficiently large diameter, from ½ in. to ⅝ in. for an adult case. It takes the place of the "bolt" of the knee-joint which is composed of its muscles and ligaments. The bar to lock or to free the joint I had placed within reach of the hand without stooping and so it may be operated without disarranging the clothing and at the will of the patient. When the joint is free, it stops the limit of extension similar to the joint of a carpenter's rule and this limit should be fixed to prevent strain from the articular surfaces from contracture of the hamstring muscles. In a vertical position the weight of the body is thus received on the ischiatic strap at the top of the apparatus. A limit to the flexion of the knee is

also to be adjusted to prevent articular pressure from contracture of the quadriceps extensor acting through the patella. These limits may be increased by following the gain in extent of motion acquired by the knee, but not by the slightest degree *exceeding* it. From the bar on the outer side of the limb furnishing the above mentioned arrangements, are attached two firm bands, one above and one below the knee, which passing behind the limb, furnish attachment for plates giving lateral support above and below but not against the knee joint. The shoe bears a steel which receives the lower end of the outside bar by a slip-joint, and the apparatus is thus readily applied by the patient after the shoe is secured to the foot. It is important that the heel of the shoe extend underneath the steel forming this slip-joint upon which rests the lower end of the apparatus.

At night the knee must have local rest, so it may recuperate from a lateral as well as a posterior aspect; flexed to a degree at which the patient finds it is at rest. Either a gypsum shell may be used, or, better, a frame composed of two steel bars bent accurately to the contour of either side of the limb in its flexed position, the one on the outer side reaching from the trochanter to within an inch of the ankle. They are connected by three or four posterior steel bands sloped to fit the posterior contour of that part of the limb with which they come in contact. The inner bar bears an oval plate bent or pounded to receive the inner side of the knee-joint, against which the knee should find lateral rest. Leather, canvas or web straps should be secured to receive the posterior surface of the limb by adjustment to its shape at, above, and below the popliteal space. The frame is further steadied in position by adhesive straps or either side of the leg, received by buckles at the lower end of the frame. As there is not traction or counter-traction, they need be only a slip ¾ or ½ inch wide, and do not need any bandage, so that the action of the muscles is not interfered with. We now have a means of carrying out a definite plan for giving the knee protection from the traumatism arising from locomotion, while at the same time the joint and limb are acquiring restoration from the effects of its disuse. It is permitted to receive weight and concussion modified to suit its strength, but is protected from the traumatic lateral jerks spoken of; it has flexion and extension limited to an arc of motion suited to its capacity, and it is given local rest at night or at other times as may be needed. The use of the limb under these circumstances is followed by increase of mobility and return of strength. The atrophy above the knee, or the swelling and puffiness of the foot and leg disappear; and the backward displacement of the head of the tibia is gradually reduced by the action of the quadriceps extensor, which has been inert for want of some limit to its action upon the joint. Without this mechanical limit every attempt at muscular use of the limb would "jam together" its articular surfaces. The accomplishment of all this requires a combination of *professional* skill with mechanical precision, to be rendered at the con ception of the apparatus, during its construction and application and at the modifications required during the progress of the case. The patient should be considered under treatment while the apparatus is in use, and the *professional* responsibility continued throughout such use, should furnish the necessary skilled advice to guide the patient in the emergencies which arise from time to time in connection with the knee and the general health.

TREATMENT OF SYCOSIS.

Kromayer (*Therap. Monatsh.*, April 1892) says that sycosis is always due to micro-organisms, either the fungus of herpes tonsurans or the staphylococcus. The two points in the treatment consist in (1) preventing auto-infection, and (2) curing the affected places. The latter is effected by depilation and the use of Rosenthal's ointment (sulphur and zinc oxide), but if thick infiltrations exist scarification or scraping may be necessary. If many pustules are present incision and the application of solid nitrate of silver may be useful. Auto-infection is prevented by depilation of the sound hairs in the neighborhood and the vigorous application of a strong spirit solution of corrosive sublimate. Thus in the evening depilation is performed and the ointment applied, and on the following morning the parts are cleansed with paraffin from the remains of ointment, secretion, etc., then disinfected with the mercurial solution and covered with ointment.—*Brit. Med. Jour.*

THE MARRIAGE QUESTION FROM THE STANDPOINT OF GYNÆCOLOGY.*

By PROFESSOR A. R. SIMPSON, M.D.,
PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH, PRESIDENT OF THE EDINBURGH OBSTETRICAL SOCIETY.

After thanking the Fellows for the honor they had bestowed upon him by electing him to the Presidential Chair, the orator briefly retraced the birth and development of gynæcology as a separate department from obstetrics, and to the *rôle* played by Scotchmen in its advancement. Pointing out that the term gynæcology comprised the study of all that concerned the well-being of the sex, as well as that of the morbid processes in individual women, he selected for the subject of his remarks the conjugal relations which must always be kept in view by the gynæcologist in treating the diseases of women, in order to render them capable of their highest function of motherhood.

It is, he said, the more necessary for gynæcologists to consider the subject that in recent times it has been fully treated of in all kinds of newspapers and magazines by writers of all varieties of mind. A year or two ago one of the daily papers intimated that it had received as many as 2,700 letters from various correspondents on the marriage question. When the laity are venting all sorts of ideas derived from sources that range from supernatural revelations to animal instincts, the trained physician will be expected to express the opinion that will correspond to the result of scientific observation, and philosophical reflection. This may especially be expected of the gynæcologist, for in the process of reproduction the *rôle* of the female is of higher import than the *rôle* of the male, and it belongs to him to consider under what conditions she may fulfil the functions with greatest safety to herself, and with best hope of producing numerous and healthy offspring.

"No excuse is needed," says Darwin, "in dealing with the effects of sexual selection, no excuse is needed for treating this subject in some detail," for as the German philosopher, Schopenhauer, remarks, "the final aim of all love intrigues, be they comic or tragic, is really of more importance than all other ends in human life, what it all turns upon is nothing less than the composition of the next generation. . . . . It is not the weal or woe of any one individual, but of the human race to come, that is at stake."

The union of the sexes that causes impregnation comes about under the impulse of a mutual attraction, so strong that the great naturalist whom I have first quoted in the application of the principle of sexual selection to evolution is led to "the remarkable conclusion that the nervous system (the medium of appreciation of sexual pleasure) not only regulates most of the existing functions of the body, but has indirectly influenced the progressive development of various bodily structures, and of certain mental qualities. Courage, he says, pugnacity, perseverance, strength, and size of body, weapons of all kinds, musical organs, both vocal and instrumental, bright colors and ornamental appendages have all been gained by one sex or the other through the exertion of choice, the influence of love and jealousy, and the appreciation of the beautiful in sounds color, and form; and these powers of the mind manifestly depend on the development of the brain."

Although the gratification of the sexual appetite is not a necessity for the individual, statistics show that the condition of celibacy is not favorable to health, a fact which is admirably shown in Bertillon's article on "Marriage" in the Dictionnaire Encyclopédique des Sciences Médicales." The table drawn up by this observer shows that the mortality is markedly higher among bachelors and widowers than among husbands, the same proportion holding good, though less strikingly, among the female portion of the population.

1. Mortality is higher among the unmarried than among the married. The tables in which Bertillon demonstrates the depreciation of the insurance value of the lives of the unmarried as compared with the married are drawn not only for France, but also for Paris, for Belgium, and for Holland. For England and Sweden he could not obtain the proper data. The

*Inaugural address as President of the British Gynæcological Society.

figures in the various columns of his extended table are so closely confirmatory of the general results, that it will suffice to look at the French table of the mortality of both sexes at different ages, as that is affected by their being on the one hand bachelors, husbands, widowers, or on the other spinsters, wives, widows.

Proportion of Deaths per 1,000 at Different Ages of the Unmarried, Married, and Widowed.

Ages.	Bachelors.	Husbands.	Widowers.	Spinsters.	Wives.	Widows.
15–20	6·89	51·32	774·	7·53	11·86	112·31
20–25	12·88	8·92	49 6	8·32	9·92	23·62
25–30	10·17	6·24	21·84	9·02	8 98	16·9
30–35	11·51	6·82	19·17	9 87	9·36	15·03
35–40	13·15	7·52	17·50	10·87	9·29	12·73
40–45	16·62	9·55	18·89	13·28	10·14	13·30
45–50	19·60	11·47	22·2	15·71	10·69	15·20
50–55	25·8	15·61	26·8	20·97	14·11	18·71
55–60	31·1	21·5	34·17	26·90	19·29	24·47
60–65	45·92	32·6	47·5	40·52	30·75	37 07
65–70	58·5	44·8	62·97	58·3	45·3	53·5
70–75	85·1	71·5	95·4	85·5	72·67	86·1
75–80	123·	114·5	143·9	140·5	109·4	126·7
80–85	202 7	182·8	221·8	222·5	172·5	198·
85–90	268·4	228·6	263·05	305	205·1	264·
90–95	282·	279·	319·	314·1	256·3	308·
95–	480·	357·	385·	387·7	416·	324·

These figures give us the proportion of deaths per thousand of the several groups at successive quinquennial periods of life. If for the moment we leave out of sight the deaths in the first quinquennium where the individuals were under twenty years of age, we observe that the mortality of the central group—the married people—is markedly less than the mortality of the group on either side. This is more distinctly seen in the case of the men, among whom between the ages of twenty and twenty-five there is a mortality of 12·88 per thousand among bachelors, and 49·6 among widowers; and only 8·92 among married men. The difference is still more striking at a more advanced period of life, as between the ages of forty and forty-five. At that age there is a mortality among married men of 9·55 per thousand, whilst among bachelors the mortality amounts to 16·62, and among widowers to 16·89 per thousand. It can, as Bertillon further indicates, be put in another form. If we take the numbers in a community, that at a given time would furnish 100 deaths among the married men, and ask what is the mortality among the same number of bachelors and of widowers we find that for 100 married men who die between the ages of thirty and thirty-five, there die, of bachelors 169, and of widowers 281. Between the ages of thirty-five and forty the proportion is—175 bachelors, and 233 widowers to 100 married men; between forty and forty-five, 174 bachelors, and 198 widowers; between forty-five and fifty the figures become 171 and 194; between fifty and fifty-five 165 and 172. The figures show that among bachelors there is a rise in the relative mortality till between the ages of thirty-five and forty-five, after which it gradually declines.

The result of Bertillon's statistics is to show that the conjugal association, provided it is not prematurely entered on, is salutary to both sexes, though it is the husband who benefits most from the union. The dangers of childbearing neutralize its benefits to the female up to the age of twenty-five in France, and in Belgium and Holland even up to the ages of forty or forty-five. "The comparison," he says, "of the vitality of married women and widows above the age of fifty with that of spinsters is very significant. It shows that the dangers of maternity are prolonged beyond that time of life. A woman who, by her celibacy, has deprived her organs of their special function, who has denied to her youth the pleasures of love, and the labors and joys of motherhood, has not thereby insured her old age against the dangers peculiar to it, but, on the contrary, she remains more exposed to them. Love and motherhood, in the salutary conditions of marriage, far from exhausting vitality preserve and protect it in the present and in the future, because in France, the mothers of families, wives, or widows, at every period of their existence after the age of twenty-five pay a smaller tribute to death than the spinsters of corresponding age."

Other interesting points are the comparative immunity of married persons, in respect of suicide and insanity, and the small relative proportion contributed by married persons to the criminal population.

When such statistics are before us we are prepared for an outburst like this from Thuliè (*La Femme*), who writes from a purely natural history and evolutionary standpoint, in dealing with the question of voluntary sterility, and asks, "This

sterility which is a shame in the eyes of men who obey natural instincts, and a glory for the ignorant metaphysicians of Christendom—what is it for modern sociologists, who base their doctrines on the knowledge of man, and not on revelation?" and he answers, "From the point of view of the individual it is an infirmity; or if the sterility be really voluntary, it is a fault which deprives the human being of joys the most profound and pure, and removes the most powerful impulse to exertion and activity. From the point of society, it is, for the races affected by it, a fatal decrepitude and, after the lapse of a longer or shorter period, their disappearance before the strong and prolific races. From the point of view of humanity, it is a danger, or at least a delay, in the progressive evolution of the race." At any rate we can see that those who try to evade the laws of physiology, which require the multiplication of the race do so under penalties such as nature teaches us always to expect to follow any rebellion against her laws.

Passing on to discuss the "physiology of marriage," we must examine the effects of the different methods, (1) in respect of fertility, and (2) in the respect of the offspring.

COMMUNAL MARRIAGE.

Of all the methods that have been sanctioned or proposed for the propagation of the race the worst is that which has been designated the "communal" or "promiscuous" or "free-love" union of the sexes. Westermarch, in his recent elaborate work on "The History of Human Marriage," tries to prove that no such custom prevails or has prevailed, though Lubbock, Bastian, and many others had formed the hypothesis that such had been the case with primeval man. But then his eagerness to establish his own hypothesis, that we derive our origin from monogamous apes, leads him to minimise the evidence on the other side, and even if it be, as he maintains, a divergence from the archaic custom, something very like communalty prevails among the North American Indians and South Sea Islanders, where it is seen to eventuate in sterilization of the women, and death or destruction of the infants. So that Thuliè says of it, "Children are scarce where the man is only a fertilizer." The mischief of it is seen nearer home in the promiscuity of the abandoned women. Were London decimated no physiologist could expect, as no philanthropist could wish to see its ranks filled up by the offspring of its forty thousand prostitutes. "Il ne pousse pas d'herbe dans les chemins où tout le monde passe," says Bertillon.

POLYANDRY.

Polandry is perhaps not far removed in its deleterious effects from communalty. It is said to prevail in some poor regions as in Thibet, among the Esquimaux, where the co-associates are usually brothers, the eldest of whom chooses a wife for the party. This kind of union is incompatible with fertility. The woman may be mistress of a household, but she has all the responsibility, trouble, and fatigue of the management, and when she dies in childbed, or soon after, the child so often perishes that the custom has grown up among some polyandrous people of burying with the dead mother the child that has not arrived at the stage of development when it can feed itself.

POLYGYNY.

Polygamy, or rather polygyny, though a distinct advance on polyandry, is still when measured by the rule we are applying an unphysiological institution. The women of the seraglio are in no wise fertile. The master may be the father of many children, but the individual wives have relatively few, and hence it is found that the birth-rate in polgynous countries is inferior to that of the populations where monogamy prevails, while the infantile mortality increases. There is thus a tendency to diminution in the numbers of polygynous populations, who are often warlike in character, and keep up their supply by raids on neighboring tribes, or by the purchase of slaves.

MONOGAMY.

Bertillon defines marriage very fully as "A synallagmatic (mutually consenting) and authentic (openly acknowledged) contract to constitute a family by which the pair, besides the sexual relations, assure each other of community of life, of effort, of interest, and of conscience with a view of mutually providing society and

material and moral support, and of securing the proper upbringing of their children." It is in such a monogamous union, in obedience to the law of "one with one mutually consenting and openly contracting," that we find the surest guarantee for the maintenance and multiplication of the race. The products of such a union are more numerous; they are healthier; they have better chances of being reared successfully. This will come out more clearly if we look at some of the consequences of infraction of this great law. Some of these consequences may fall on either of the individuals who break the fence that Nature has set around the procreative processes. But we concern ourselves here with the consequences of the female.

DANGERS OF INFRACTION OF LAW.

We ask, What are the risks to a woman yielding herself to a seducer, *i. e.*, to a man who has not openly declared his readiness to assume martial responsibility.

1. She may become tainted with *syphilis*. Of course, this might happen to a woman formally married, who had not been careful to ensure herself against damaged goods in the making of her bargain. When the day comes for the righting of the wrongs of women the law will do something to protect her from this injury, or compensate her where it has been inflicted on her innocence. Assuredly if it had been the rule that this disastrous element was introduced into the marriage contract by the wife instead of being, as in the case, the rare exception, we men would long ago have found legal means of freeing ourselves from partners whose condition was a danger to us and our offspring. However this may be, the unmarried woman is in danger from infection, whether by inoculation of a primary sore or transmission through a tainted ovum, and how mischievous the syphilitic virus is in aggravating many female disorders and in lessening the powers of reproduction is but too well known to every general practitioner.

2. She may contract a *gonorrhœa*. Up till a recent period this would have been regarded as a comparatively trifling ailment, and in some text-books on surgery it is still too slightly dealt with. But since Noeggerath published his remarkable pamphlet in 1872 on "Latent Gonorrhœa" gynæcologists have become more and more alive to the pernicious effects of this often insidious malady, and Professor Sinclair and some others have shown its virulence in initiating some of the most painful and protracted illnesses of women, and leading all too often to their hopeless sterilization.

3. She may become *pregnant*. Escaping the pathological risks of illicit intercourse the physiological result may follow, and she finds herself impregnated. There is no time at which she can be sure that conception will not follow the insemination. If she counts on an agenetic period she may be mistaken; if on preventive measures they may fail her; and that which to her married sister brings the brightest hope befalls her as the darkest dread.

In her unsheltered solitary state the ordinary dangers of pregnancy and parturition and the puerperium are all aggravated by many degrees. The woman who has become impregnated within the physiological limit is surrounded with all the guarantees for health and safety. She has a nervous system that is calm, or subject only to the exhiliration of anticipated joy, her circulation goes on steadily, or is healthfully stimulated at times to more activity: food, clothing, and every comfort are at her command. She can give due attention to the state of her emunctories. On the other hand, nervous depression, circulatory disturbances, imperfect food and clothing, and frequent contradiction of the ordinary conditions of health are the lot of the woman to whom pregnancy has come outside the limit. Hence the tendency to melancholia, to convulsions and other grave disorders of gestation, and the risks of a higher childbed mortality, and where her life is spared she is more likely to come out of her lying-in-room the subject of disease or damage that might be a source of life-long trouble.

Then when we turn to consider what the chances are to her infant we see that the risk is great of its being still-born, or that it may be delicate or difficult to rear. In France the difference between the still-birth rates respectively of legitimate and illegitimate children is enormous. According to Bertillon the proportion is as 100 to 193. Transgression of the law that requires open recognition of the union between parents almost doubles the mortality of the pregnancy at birth. If we follow

the fate of the living children born of unmarried women we find that whilst in 1,000 legitimate births 35.12 of the infants die in the first week, in 1,000 illegitimate births 63 of the infants die within the week. Within a month the mortality among legitimate children amounts to 74.7 per 1,000, amongst illegitimate to 170 per 1,000, and while the legitimate children have a mortality of 175 per 1,000 in the first year after birth, the mortality of illegitimate children within the same period is 337 per 1,000.

To have determined the kind of marriage relation that is most conducive or successful to propagation does not, however, exhaust the duty of the gynæcologist who is consulted as to the best conditions under which the relation may be entered on. He has to consider further, *e. g.*, the question of

1. *The Marriageable Age.*—Bertillon's tables show that mortality of married males prior to the age of 20 is extremely high. At all the ages beyond, as we have already seen, the marriage relation exerts such a favorable influence on the life conditions that the mortality among the married men is far below that of the bachelors. But on the contrary, when marriage is entered on before the age of twenty it has a prejudicial influence on life and whereas the mortality among unmarried youths between the ages of fifteen and twenty is only 6.89 per 1,000, those who marry under twenty, usually between eighteen and twenty, are at the rate of 51.32 per 1,000. Where among the unmarried youths the mortality is only 14, among the married it amounts to 100. Bertillon believes that the beneficial influence of marriage which is so marked at the age of twenty-five and upwards is "still considerable," "still manifest" and twenty-three, perhaps "still sensible" at twenty-two, but would cease at twenty-one. "Who can object," he asks, "to the conclusion that these early marriages are deadly, that the law which permits them is a snare which the ignorance of the legislator has spread for our youth, and that this bad law should be abrogated?"

The danger of early marriage is not so pronounced in the case of women, and the beneficial influence does not begin to show itself so early as in men. The table shows us that the proportion of deaths per 1,000 for the unmarried between the ages of fifteen and twenty years of age is 7.53, and for the married at the same age 11.86. There is already an improvement between the ages of twenty and twenty-five at which the majority among the unmarried is 8.32, and among the married 9.92. It is the danger of parturition, and especially first labors, that keep up the mortality among married women during their productive life, but we can see that these dangers become attenuated as they advance in years, and the figures show us very distinctly how specially dangerous it is to enter prematurely on the reproductive career. Whilst the relative mortality of spinsters and married women between the ages of twenty and twenty-five years is as 100 to 119, their relative mortality between the ages of fifteen and twenty is as 150 to 158 in France. The proportion in Holland is 100 to 208, so that there a young woman marrying before the age of twenty doubles her chance of death. When we know besides that the products of these early marriages are apt to be more feeble and difficult to rear, and that women who marry early are likely as not to have fewer children, we conclude that it is not advisable for a woman to contract a marriage before the age of twenty. In general terms we may say that after an individual has passed the first septennium of life and has got the permanent teeth, during the second septennium the building up of the system goes on which prepares for the evolution of the several apparatuses. This occupies the third septennium, so that it is only at the age of twenty or twenty-one that the pelvic organs with the associative mammæ are fairly ripened and capable of carrying out their function. And as it has required all these years for the full physical development of the woman, so in her physical training we cannot expect of her at an earlier period to be able clearly to apprehend the relations on which she is entering, and intelligently to face the lofty requirements of motherhood. Of course, in all these data we speak of averages, and in the corporeal and mental development of women we may find diversities in the data of their completion just as there are differences in the date of the eruption of the first teeth in infancy which we would look for at the seventh month, though in some infants they appear earlier and in others later. So we may meet a

wise and well developed woman of eighteen whose marriage we might conscientiously sanction, whilst we might have grave doubts as to its propriety with a giddy girl of thirty. "In women," says Matthew Duncan, "the age of maturity is twenty to twenty-five, in men it is later, probably by at least five years, and you will pardon the interpolation here of the reflection, well worthy of being dwelt on, that this lately ascertained physiological law tallies with the oldest and wisest counsels as to the nubility of men and women, a part of the grand subject of morals and medicine. At this age a woman has the lowest risk of sterility, the greatest likelihood of having healthy children that will long survive, the greatest likelihood of herself surviving childbirth, the lowest risk of having abortions, of having excessive family, of having plural pregnancy and of bringing forth idiots."—*Lancet* 1889.

It is not in the ill effect on the individual that the mistake of premature reproduction appears, but in the imperfect development and low vitality of the products of such unions, evils that show themselves in modified forms again in the children of those too advanced in life. The differences of the two classes are summed up by Dr. Strahan in his recent work on "Marriage and Diseases," as follows:—"The children of *immature* parentage are especially liable to death during infancy from wasting, scrofulous and convulsive affections. They are liable in a remarkable degree to idiocy and imbecility of a low type, and to physical deformities and imperfections. Large numbers of them succumb to tubercular disease about the age of puberty and adolescence, and few of them attain even advanced middle age. The genital organs are ill developed and often deformed, and a great number of them are sterile. They are also notorious for their lack of energy and courage. Hence the class of criminals to which they give the greatest number of recruits is that of thieves and other petty offenders. The children of the *senile* are as a class ugly, small of stature, and stooping, which, together with the absence of subcutaneous fat, gives them a look of old age while still young. Idiocy is less common among them than weak-mindedness, amounting to imbecility, which is often accompanied with more or less perversion of moral feeling, and a plentiful supply of low, deep, cunning. Many of them die between the ages of puberty and adolescence of tubercular diseases, few of them live past middle age, and a great number of them ultimately become insane and criminal. They are nervous, irritable, passionate, and horribly cruel, and are the perpetrators of most of those fiendish barbarities, the recital of which from time to time shocks the civilized world."

2. *Physical bars to marriage.*—Besides the determination of the age of nubility it belongs to the gynæcologist to consider what physical conditions are to be regarded as contra-indications to the marriage relation. Regularity of the menstrual flow may usually be taken as a sign of fitness for procreation, though it may consist with morbid conditions, such, for example, as deformities of the pelvis that would under the process prove dangerous to both mother and child, and that would make it inadvisable for the affected individual to marry. The irregularity or absence of the flow ought always to be taken as a possible indication of the presence of some condition that will inevitably cause an infertile union. Some of the associated conditions may be remedied, such as an imperforate hymen; but we have all seen cases where the marriage knot should never have been tied, of congenital atresia vaginæ, or infantile, or otherwise imperfectly-developed uterus, and the fruitless union has been a mutual disappointment. From such distress the gynæcologist could in almost every instance save the parties if only the people were taught enough of physiology to understand the circumstances that ought to lead them to seek his counsel.

Besides the malformations of the generative apparatus there are other organic defects or constitutional tendencies that ought to make our patients pause before they encounter the risk of reproduction. Dr. Robert Barnes has repeatedly, with characteristic lucidity and vigor, and with abundant wealth of illustration, demonstrated how searchingly a pregnancy will test the vital powers of women, calling out latent tendencies, aggravating already existing disorders, and adding an element of danger to otherwise trifling maladies, and there are some of these, such as recently acquired incompetency of the cardiac valves, especially the aortic, in which to withold the warning as to the dangers

of parturition would be downright cruelty.

In regard to this matter, also, we have not only to keep in mind the consequences to the wife, but to anticipate the influences on the offspring. This opens up the wide field of heredity, which bids us to remember that a woman who is the subject of some infirmity may not only suffer for herself in the reproductive process, but may transmit her weakness to her children. So great is this risk in the case of mental disturbances that Maudsley has said, "If we are seriously minded to check the increase or lessen the production of insanity, it would be necessary to lay down rules to prevent the propagation of a disease which is one of the most hereditary of diseases." Strahan insists that "all men and women who have been insane once, and have a bad family history, those who have been twice insane, even if the family history be good, and all who are confirmed epileptics or drunkards, should be prevented by the State from becoming parents, for," he maintains, "they have no greater right to carry suffering and contamination amongst the people and throw expense upon the State than has the person suffering from small-pox to do so by travelling in a public conveyance." It is not only in the aggravation and propagation of neuroses, such as insanity, epilepsy, drunkenness, idiocy, deaf-mutism, and such-like that we see the ill effects of injudicious unions. They are seen also in the transmission of dangerous diatheses, such as the cancerous, tuberculous, syphilitic, and rheumatic, which are apt to determine the production of children prone to death, all the more if the parents have any close degree of consanguinity, or if they are both in any marked degree the subjects of the diathetic influence.

3. *Regulated Marital Intercourse.*—The gynæcologist has to consider not only what may be the proper age for entrance on the reproductive career and the physical conditions, local or constitutional, that may be an embarrassment or even an actual bar to the process, he has to be ready to indicate the conditions under which it may be healthily carried out. According to Herbert Spencer the progressive evolution of the race proceeds under the varying influences of what he speaks of as individuation and genesis. In the former term he includes all the race-preservative processes by which individual life is completed and maintained; in the latter the processes that go to the formation and perfection of new individuals, and he shows that individuation and genesis vary inversely, genesis decreasing as individuation increases, but not quite so fast, so that progressive evolution in the direction of individuation is associated with a diminishing rate of production. This might at first sight seem to sanction the idea that the married pair might be encouraged to rapid reproduction for the multiplication of the family. But we have to keep in mind what has been indicated by Eddes and Thomson, in their remarkable work on "The Evolution of Sex," that "the survival of a species or family depends not primarily upon quantity, but upon quality. The future is not to the most numerous populations, but to the most individuated." This consideration suggests to us the warning that the pair who would build up a family must see to the production not of many children, but of a moderate number of children, who are more likely to be healthy, and for whose up-bringing they are more likely to be able to provide. The experience of every physician must confirm the authors I have quoted, when they deem it "essential to recognize that the ideal to be sought after is not merely a controlled rate or increase, but regulated lives. Neo-Malthusianism might secure the former by its more or less mechanical methods, and there is no doubt that a limitation of the family would often increase the happiness of the home; but there is danger lest, in removing its result, sexual intemperance become increasingly organic. We would urge, in fact, the necessity of an ethical rather than of a mechanical prudence after marriage, of a temperance recognized to be as binding on husband and wife as chastity on the unmarried. When we consider the inevitable consequences of intemperance, even if the dangers of too large families be avoided, and the possibility of exaggerated sexuality becoming cumulative by inheritance, we cannot help recognising that the intemperate pair are falling toward the ethical level of the harlots and profligates of our streets."

THE DIM AND DISTANT FUTURE.

Gentlemen, if William Hunter's eulogist was rather gallant, than absolutely ac-

curate, in saying that, "the faults of women are the work of men," there is enough of sober truth in the averment to suggest to us the obligation that lies on us, as men as well as gynæcologists, to do our utmost to mitigate the ills that come to women so often from their submission to the stronger sex. As this Society has already done good service in the discovery of means to recognise and remedy the diseases of women, so we are confident it will continue and extend its beneficent operations. But gynæcology and gynæcologists will only have rendered their full service to their subject when they have secured such intelligent apprehension of the laws that regulate the physiology of reproduction, and such implicit obedience to these laws, that a race shall have been evolved that will be independent of their aid. The time is long, and the way far, to such a consummation, but our Society and we ourselves shall only achieve our cest while we keep in view the highest of ideals.

A THEORY OF THE FUNCTIONS OF THE SINUSES OF THE FACE, THE CELLS OF THE ETHMOID, AND THE MASTOID APOPHYSIS.

Coüetoux (*Ann. des mal. de l'oreille et du larynx*, xvii,3) gives the following epitome of his views on the above subject: The ethmoid is primarily a respiratory and olfactory organ. The sinuses of the face share in this rôle and later diminish its influence. Olfaction seems to owe its mechanism to the alæ of the nose and the vault of the palate. The ethmoid aids in the formation of the nasal fossæ, and preserves them from the deforming efforts of aspiration in diffusing them. The moist and overheated air which it contains pushes the odoriferous particles toward the convexity of the middle turbinated bone. The sinuses, being developed with the olfactory sense, share with the ethmoid in its functions of diffusing the deforming effects of the negative pressure due to olfactory respiration. In the adult the sinuses leave to the ethmoid the first place. The mastoid cells relieve the tympanic membrane from the deforming effects of the barometric vacuum, which is due not so much to the olfactory respiration from which the narrowing of the eustachian tube already protects it, as to the effects of this narrowing, which coincides with the development of olfactory respiration.

DYSMENORRHŒA AND PAINFUL OVARIES.

By A. E. WARREN, M. D.
GIRARD, OHIO.

The term dysmenorrhœa is generally used as meaning pain before, during, or after menstruation. During my experience I find physicians treating this pain as a symptom with such drugs as antikamnia, phenacetin, and opiates; many physicians become accustomed during their busy period to prescribing indiscriminately, not asking as they should for a cause, but hurriedly giving anything to alleviate pain for the time being.

Let us for a moment refer to some of the causes of dysmenorrhœa which prevails more especially among society girls. The normal menstrual flux is generally accepted as an overflow, and any uneasiness during this period is abnormal, e. g. imagine the os internum closed, either with cicatricial tissue, new growth or a firm spasmodic contraction. This causes a daming back of the normal overflow, a distension and pressure on nerve endings. Menstruation being caused by a change in the lining of uterus, any retention of blood pressing on these already vascular, and irritable tissues causes pain. There also may be atresia of vagina; an imperforate hymen; disease at or near os internum; anything arresting growth of generative organs, retroversions, anteflexions—all these abnormal conditions and malformations cause a backing up and retaining of the normal monthly flow. W. G. Wylie in his article on menstruation, and its disorders (Mann's Gynæcology) says, "A uterine sound that could be passed into a normal uterus without pain, would cause severe aching pain (similar to that of menstruation) if passed into the uterus of a patient suffering from dymenorrhœa." From this we might be led to believe that it was the passing of the secretion over this irritated part that caused the pain, but in a great majority of cases the pain ceases at the appearance of the discharge. Whichever of the above mentioned causes may be operative, the profession, I think, will agree with me when I say obstruction, whether from disease or malformation, is the leading one, and that it is to the treatment of this class of cases I want to draw your attention.

Case: Miss H., aged eighteen, came to me April 1 suffering with pain in right side over the region of the ovary. This pain dated back one year, she had since the beginning of her first menstrual period four years previous, suffered with dysmenorrhœa so severe that she would be confined to bed two and three days prior to the appearance of the flow; the pain in right side was continuous but exaggerated at each monthly period. At the time Miss H. came to me, five days after her monthly sickness, she was very nervous and somewhat anæmic; her occupation requiring considerable brain work. I had her give up her position, and put her on the following tonic:

℞
Ferri. Red.....2. grammes.
Zinci. Val.....2. grammes.
Acidi. Ars.....0.05 grammes.
Strych. Sulph.....0.05 grammes.
Quin. Sulph.....1. grammes.
Ft. Capsules xxx.
Sig.—One, three times day.

I told her to return to me ten days prior to next menstrual time. I then ordered a douche, of 120°F, or as hot as she could bear, every day until the flow appeared. I also prescribed on the day previous to the menses capsules every four hours, containing in each, aloin 1/8 gr., ext. ergot 1/2 gr. The douche, softening, relaxing and causing a congestion; the aloin I prescribed to congest, the ergot to contract. Five days after she returned stating she experienced no pain before or during sickness, but still suffered from pain in the right side, the area of which could be covered with a silver dollar. I decided this was an irritated ovary from long-standing dysmenorrhœa. Absorbent cotton saturated with a solution of ichythol, grammes 8 to glycerine 60, was intoduced into vagina and left three days, and repeated until time to begin douche, which was repeated for the second time. This period passed over without pain, the pain in side ceased; since then the patient has been entirely well. Later I used the same treatment on four other cases, with a complete cure in each case.

COPPER IN ADYNAMIC ANÆMIA.

Luton and Liegeas have found copper (*Prog Med.*) of value as a tonic alterative nervine. Pearson (*Medical Standard,* Feb., 1892) points that in adynamia, a kind of nervous asthenia, copper is of value, as it stimulates the cardiac and capillary circulation and acts as a nervine tonic.

Society Reports.

CLINICAL SOCIETY, OF LOUISVILLE.

Stated Meeting June 21, 1892

Dr. J. M. Mathews, president *pro tem*, in the Chair.

CASE OF OVARIAN TUMOR.

Dr. W. O. Roberts: The patient from whom this specimen was removed is in her sixties—sixty-two or sixty-three, does not know her exact age; she is an exceedingly fat woman. There have been removed from this patient at different times, four tumors from the breast. I removed the last one, which was eighteen years ago; examination showed it to be a malignant growth; there has been no recurrence. About three years ago she had an umbilical hernia a portion of which was irreducible and gave her a great deal of pain. I operated upon it and found the irreducible portion to be omentum, which was tied off and the opening closed. She got along without any trouble for a year, then there was a recurrence of the hernia and I operated again with the same result. The hernia recurred again and grew rapidly, so that at the time of the last operation, a few days ago, it was nearly as large as a hat crown. When I cut down upon it I found the intestines, especially the large intestine, adherent so that it was with some difficulty I was able to detach it. After it became detached she had a violent vomiting spell, and a large amount of intestine protruded through the opening. In replacing the intestines my hand came in contact with a solid body, and upon examination it proved to be an ovarian tumor, which was removed. It was a simple multilocular tumor, the largest cyst of which was tapped, and I suppose about a quart of fluid came out of it, a thin gelatinous fluid; you will notice there are several smaller cysts. This tumor was not suspected prior to the operation for hernia, and but for the fact of the patient vomiting and expelling the intestines through the opening, I suppose it would not have been detected during the operation.

TUMOR OF THE BLADDER.

I also have a tumor which has already been exhibited to one of the Medical Soci-

eties, but as it and the history of the case is of considerable interest, and as there is a very important point in connection with the case that has come up since report was made to that society, I would like to again mention it: The patient from whom the tumor was removed is a man fifty-seven years, of age, and a patient of Dr. Palmer's. He had been troubled for some months with frequent and difficult micturition and last January became unable to urinate at all, so that a catheter had to be used. I saw him in March and up to that time he had been unable to void his urine, catheter had to be used sometimes every half hour during the day and very frequently at night, his urine was loaded with pus. We made an examination under chloroform, found no stone but there was some little difficulty in getting into his bladder and we were under the impression that he had an enlarged middle lobe, the lateral lobes did not seem to be at all enlarged, He He was put on boric acid internally and locally, and he returned to the city about the middle of May very much improved as regards the condition of his water, also as to the frequency of need to use the catheter. He would go from two, to three hours without using the catheter. We advised a suprapubic cystotomy, which operation was done at the Norton Infirmary. When we reached the interior of the bladder, we found a tumor about as large as the first joint of your finger, that completely closed up the neck of the bladder. It was a pedunculated growth. I caught it with forceps and in pulling it tore off a considerable sized piece, and then afterward picked it off little bits at a time until it was entirely removed. After the operation I used the kind of drainage tube which is used by Keyes, of New York, whether it is his original idea, or not, I do not know but it is an excellent tube. This man remained in the hospital I think for two weeks, possibly a little longer. When he left for his home the urine was still being passed through the abdominal wound. The drainage tube was taken out, or rather it came out in an effort to vomit, and in attempting to replace the tube it gave him so much pain I desisted and finally concluded to leave it out altogether and see whether or not after closure of the wound he would be able to void his urine the natural way. He returned to his home as I said about two weeks after the operation, and a day or two ago I received a letter from Dr. Palmer which was written by the patient's son, a doctor, graduate of Jefferson College, under date of June 16th, a little over a month after the operation, as follows: "My father is doing very well indeed, the wound is almost closed, passes urine the natural way with but little leakage through the abdominal wound, then only when he is urinating. Has to get up only a few times at night to empty his bladder. There is still some pus in the urine. He passes urine with sufficient force to throw it at least three feet from him."

I think this is of great interest in view of the man having had retention of the urine for so long a time.

Dr. S. Flexner: (of Johns-Hopkins Hospital Baltimore) I would like to ask Dr. Roberts whether this tumor did not spring from the inside of the bladder. I understand it has not yet been examined. The commonest form of tumor springing from the mucous membrane of the bladder is the papilloma. This does not appear to be a papilloma. I think it would be very desirable to have an examination made so as to know the exact nature of the tumor.

Dr. W. C. Dugan: Was there any serious hæmorrhage at the time of operation, and if so how was it controlled?

Dr. W. O. Roberts: The hæmorrhage was very slight; I used only hot water.

PUERPERAL TETANUS.

Dr. J. W. Irwin: The patient of whom I shall speak was not quite seventeen years of age. She was sent to me from another city. I saw her for the first time in January, 1892. She had reached the ninth month of utero-gestation with her first child. She was of medium height, strong and healthy, of dark complexion and weighed 130 pounds. Her previous history did not reveal any hereditary nervous or mental disorders, or troubles of any kind. The organs of digestion were in a healthy condition, there was no œdema, the kidneys were found to be free from disease. On February 13th at full term she gave birth to a female child which weighed seven and one-half pounds. The labor lasted nine hours and was less severe than is usually the case in primiparæ. The amniotic fluid was not excessive in quantity, and the abdomen was unusually enlarged. The placenta came away eighteen minutes after the birth of the child. Very little

hæmorrhage occurred. All clots and shreds of membranes were carefully and thoroughly removed. The vaginal tissues were found to be free from abrasions and there was no laceration of the neck of the womb. The patient had not been exhausted by the labor.

Thirty minutes after the birth of the child the patient became very weak and faint, and the action of the heart grew slow and feeble. Evidence of internal hæmorrhage was sought for and none found. The patient's head was then lowered beyond the horizontal line of the body but the alarming condition continued for fully forty minutes. My esteemed friend, Dr. Washen, was sent for to see the case in consultation, but, on his arrival, the patient was revived. A careful examination of the case failed to discover the cause of the alarming symptoms. There was no cardiac disorder and the kidneys were found to be free from disease. The patient had been well nourished and had not been exposed to cold or dampness.

From this time the patient did not have a symptom indicating any disturbance until on the morning of February 24th, or eleven days after her confinement, when she felt a choking sensation in the throat and a fulness about the jaws. She had pain in the back and the head was drawn slightly backward. There was a sense of tightness around the waist and in the chest. She complained of a tremulous feeling and at the same time the body was drenched with perspiration. On the night of February 24th, the patient did not sleep owing to severe paroxysms of pain in the back, which at times encircled the body. On the morning of February twenty-fifth, the jaws had almost closed. Barring an occasional attack of trembling in the masseter muscles, the muscular contractions about the face were permanent. The muscles of the back, chest and abdomen were firmly contracted and accompanied by a feeling of suffocation. Respiration was irregular and only twelve to the minute. The lochia was unaffected. The axillary temperature was 102⅖° F. The urine was scanty and of a dark brown color and it did not contain albumin. Pain in the back and chest was continued but it was more severe in paroxysms. There was much hyperæsthesia present and exposure to temperature of 70 degrees caused the patient great discomfort. The bowels were sluggish but small doses of saline laxatives caused free movements.

The expression of the patient, as well as her general condition, showed that something more severe than an ordinary fever had attacked her. The face wore the expression of intense suffering. The occipito-frontalis muscle was contracted tightly, which caused the flesh and skin over the forehead to stand out in numerous hard bunches, between which were deep fissures running in every direction. The brows were drawn downward and inward which gave to the eyes a sunken appearance. The muscles of the nose, cheeks, lips and chin were in a state of contraction like those of the forehead. The wings of the nose were drawn outward and upward, which gave to that organ a flattened appearance. The eyes were suffused and the lids were so much contracted as to cause the impression that they were too short to cover the balls.

On February 27th at nine A. M. the temperature was 100⅖° F., pulse 124, weak and irregular; at nine P. M. temperature 101⅕° F., pulse 130 and feeble. Perspiration now occurred in paroxysms and after severe attacks of pain. Hyperæsthesia was more felt. Pain and contractions of the muscles of the back were more severe at night. Frequent paroxysms of nervous trembling attended by copious perspiration prevented her sleeping. February 27th at nine A. M. pulse 129, respiration 16 and irregular, temperature 100° F., at nine P. M. temperature 101⅕° F., pulse still irregular and feeble and patient on attempting to move or turn in the bed had attacks of pain accompanied by oposthotonus. From this time until March 16th the condition of the patient remained practically unchanged. Twice within the previous sixteen days the patient's temperature fell to 96°. F. in the morning, but as evening approached it went up to 99° and 100° F. At no time during the course of the disease did the patient's temperature exceed 102⅖° F., and this occurred once only, at the beginning of the attack. The temperature usually ranged between 99° and 100° F. The pulse varied very much in numbers and character, at times 108 and 160, irregular, and quite feeble.

On March 16th the jaws became

relaxed and the mouth could be opened without much effort to the extent of admitting the handle of a spoon.

The muscles of the chest and back had become relaxed and the paroxysmal contractions occurred less frequently. Pain was not as constant. At the end of six weeks from the beginning of the attack the patient was allowed to return to her home. A letter was received from her bearing date of April 14th saying that she was entirely well.

The treatment of this patient, owing to the fixed condition of the jaws, presented some difficulties but the absence of an upper molar tooth made the task much easier than it otherwise might have been. The act of swallowing was difficult and painful and occasionally fluids escaped through the nose, The diet consisted of milk, consomme, liquid peptonoids, and strained soups. To this was added from six to eight ounces of whiskey daily. The hypodermic use of one-half grain doses of sulphate of morphia as occasion required for relief of pain, was found to be servicable. Insomnia was a troublesome concomitant of the disease, and this condition I found to yield to twenty grain doses of the hydrate of chloral, every second hour, better than to any other remedy. Sulphonal and chloralamide were given without any effect.

Later in the disease a mild, continuous current of electricity was applied to the spine, but as it caused too much pain, its use was abandoned.

Iron and quinine were given in tonic doses with apparently good effect.

From the description of the case I have just given, it will be observed as one of those rare affections following parturition, known as puerperal tetanus. In looking over the literature on this disease, I find that many obstetricians have never seen a case of puerperal tetanus. In Galabin's Midwifery, page 698, I find the following statement: "Puerperal tetanus is extremely rare, (in Great Britian), no instance of it occurred in 47,089 cases in Guy's Hospital Lying-in Charity."

From every source, including the carefully collected cases of Dr. Garrigues published in the *American Journal of Obstetrics*, volume 15, page 769, I find only thirty-two instances recorded as having occurred after full term in Europe and America during the last one-hundred years. Currie reported to the Medical Society of London the first case in 1792.

The disease occurs more frequently in hot countries and the mortality is very great. Parvin's Obstetrics, page 598, gives the mortality in hot countries as $80\frac{4}{10}$ per cent. The mortality in Europe and America in cases occurring after parturition at full term is $84\frac{4}{10}$ per cent. These remarks do not apply to tetanus occurring after abortion, for, in such cases, the mortality is even greater. Twenty-eight recorded cases of tetanus following abortion show a mortality of $92\frac{8}{10}$ per cent.

Until within the last few years the cause of this terrible disease was thought to be difficult labor, the retention of membranes in the womb, nervous excitement, mental distress, and exposure to cold and dampness. Climate, it was thought, conduced much to the number of its victims.

In 1885 Nicolaier discovered the cause of tetanus to be a bacillus which corresponded to the Koch bacillus of the septicæmia of mice, which is especially found in horse dung. Rosenbach, in 1886 confirmed the discovery of Nicolaier and from their combined evidence, the disease, it is now believed, is infectious in character, and communicated chiefly from horse dung.

Dr. J. A. Ouchterlony: The paper read by Dr. Irwin is extremely interesting, not only because of the rarity of the disease, but because of the fortunate issue. The best resumé of puerperal tetanus or tetanus occuring in connection with abortion, labor and in non-puerperal state in woman that I have ever read is that of Prof. Simpson, which is found in his miscellaneous works. He reports quite a number of cases as having occurred, not only in connection with labor at full term, but also after abortion. A very interesting report of a case that he gives is that of a woman who had an intra-uterine polypus. He describes it, if I mistake not, as a cellular polypus, that it was extending into the vagina and came away almost without any effort at assistance, so that there was no damage done to the parts by surgical procedure; that a few days after the exit of the polypus, tetanus developed and the woman died. The number of cases of abortion followed by tetanus that Simpson reports is quite considerable in view of the rarity of the disease. In the cases that occurred after

labor, my recollection is that it was observed quite as frequently in women who had not particularly hard labor, and where there had been no instrumental interference.

The only point I want to call attention to is one relating to the prognosis: Whenever the disease lasts longer than four or five days, it usually terminates in recovery, so that if you can tide the patient over the first five or six days, the probability of recovery greatly increases.

In thinking over the subject it has often puzzled me how to account for tetanus in puerperal women who have seemingly been entirely free from any exposure to what is now considered the cause of the disease, namely the peculiar bacillus. I have studied a number of reports of cases and must confess it was very difficult for me to see how the infection had taken place. The same difficulty, however, is encountered when we try to explain the occurrence of tetanus as an endemic disease. There is what is called idiopathic-tetanus, and it is just as difficult to understand how the infection occurred then. Of course the same thing is true in regard to a number of other infectious diseases. I have never seen a case of puerperal-tetanus.

Dr. S. Flexner: I have been very much interested in Dr. Irwin's report. I have never myself seen a case of puerperal tetanus, and only wish to say a few words with reference to the peculiar bacilli causing the disease. The recent work of Kitasato on tetanus, which is too recent to have appeared in the authorities quoted here this evening, indicated that the *several* organisms originally considered to be the cause of the disease, are not the cause, but that it is caused by a *single* organism. A great deal of difficulty has been met with in the study of tetanus from a bacteriological standpoint, because of the fact that the peculiar bacillus does not grow under ordinary circumstances, but requires the exclusion of oxygen. It will grow in an atmosphere of some other gas than oxygen, hydrogen usually being used to replace the oxygen, and it is hence an anærobic organism. On account of this peculiarity, the bacillus of tetanus is not as easily separated as other germs which grow in the presence of oxygen. The method introduced by Kitasato consists of heating a culture which contains the bacillus of tetanus mixed with other things, to a temperature at which all of the vegetative organisms are destroyed, and, under which circumstances the tetanus-germ gives rise to spores which resist this temperature and may be grown out into form of tetanus-bacilli. The organisms of tetanus have been found in the earth, commonly about stables, often in gardens and tend to grow in particular localities; for instance, certain portions of Long Island are noted from the fact of the development of tetanus following injury in great regularity. With reference to the occurrence of idiopathic-tetanus to which Dr. Ouchterlony referred in his remarks, I cannot help considering that Dr. Irwin's example is hardly one of that class. It seems to me that the case Dr. Irwin reports must be considered as one of the traumatic variety, as the act of parturition itself suffices to produce a lesion which can in some manner become infected. As to the mode of infection—the hands and instruments have to be considered. The danger of infection through the air, while not totally excluded, perhaps, is not nearly so great as the former. The peculiar organisms of tetanus are now known to develop only locally at the seat of the injury; they never invade the blood and tissues, but produce a poison known as the tox-albumin of tetanus which gives rise to the constitutional effects of the disease. The fact of the local development of the organisms indicates to us where antiseptic measures are to be applied, and, moreover, the source of danger in carrying the infection from one to another. It is to be emphasized that all the secretions from the affected part, are to be thoroughly disinfected.

Dr. A. M. Vance: I would like to ask if anybody has any information concerning the contagious nature of tetanus. I ask this question for the reason that some time ago I saw a case which seemed to prove conclusively that it is contagious. In this instance a drainage tube was used on a patient suffering with tetanus, and afterward used on another patient who developed tetanus and died in nine days. I think I had the same year seven or eight cases of tetanus. I am inclined to believe that very often these cases can be traced to cases that have gone before in the same neighborhood, in the same house, etc.

Dr. J. G. Cecil: I have never seen a case of tetanus in the puerperal state. Some time ago, however, I had occasion to look the subject up and was very much interested in it, especially on account of its rarity and its pathology. Many cases, I think, that are otherwise obscure might be traced to the dust of the street. However, I cannot see how the case reported by Dr. Irwin could have been infected from this source. I would rather consider it a case of traumatic instead of idiopathic tetanus I believe that in every woman no matter how complete and easy the delivery, the genital tract is sufficiently abraded and wounded to afford opportunity for the absorption of material, septic and otherwise.

Dr. I. N. Bloom: The micro-organism theory of tetanus was very well established in an instance I recall, where there was a large stable in the vicinity. There had been on an average from ten to fifteen deaths from tetanus in that immediate locality per year. Afterward the stable was thoroughly overhauled and disinfected, and there was but one death from tetanus in a year; after that period for a year or two there was not a case of tetanus, showing the benefits derived from asepsis also proving almost conclusively the theory regarding the origin of tetanus.

Dr. J. W. Irwin: I have very little to say further on the subject, excepting as to the prognosis. Dr. Ouchterlony has mentioned as a fact that if the patient survived four or five days the chances for recovery were greater. I think the most important point touching upon the question of prognosis, is the time at which the patient is attacked by the disease. If the tetanus comes on late after the traumatism, the patient has very much better chances for recovery than when it comes on earlier. In the case I have reported, the disease made its appearance on the eleventh day.

In regard to the question of disinfection: The patient had her own nurse which she brought with her from another city,—a trained, accomplished woman. She made use of a disinfectant solution of carbolic acid and boric acid—about five per cent. of pure carbolic acid in a saturated solution of boric acid. She always washed her hands in this solution after coming in contact with the patient in any way. The water for ablution was always boiled and some of the solution always added to it before being used. No internal washing was practiced, no syringe used for any purpose. In attending the woman, I used carbolated vaseline after first washing my hands in the water and solution above referred to. The patient was confined in a fine, elegantly-furnished house, on the first floor, second room from the front. There was no horse-stable on the place. There was a vacant lot on one side of the house, and plenty of ventilation and plenty of pure air. The house stood within about ten feet of the sidewalk. The street in front of the house was paved with granite, and of course there was a great deal of travel backward and forward over the street. If she took the disease from horse-dung, it is evident that it was deposited on the street and carried by the wind into her room.

Concerning the infection in this case from any other cause: I have not attended a case of tetanus before in eight years, and never before have seen a case of tetanus following parturition. This is the first case in my experience, and I hope it will be the last, although the results are far more encouraging than I had hoped for. I do not think with Dr. Ouchterlony that this was a case of idiopathic tetanus, and I have classed it as traumatic tetanus, the act of labor itself being the cause of the traumatism. No case could have been attended any better so far as antiseptics are concerned, than the case I have mentioned. To show that the patient is entirely well, I will read a portion of a letter recently from her: "I am overjoyed to tell you that I am entirely well and look just as girlish as ever. I will never forget you for your kindness."

Dr. J. A. Ouchterlony: It seems to me that the subject is very much like that of erysipelas. The general belief is that erysipelas is always produced by infection through some abraded surface, and it is very likely the so-called cases of idiopathic tetanus are those in which we have not been able to establish the assistance of trauma, it is possible, however, that it may exist. Of course parturition places woman in a condition most favorable to infection, the abraded surface of the uterus constituting the surgical condition.

SPECIMEN OF OVARIAN CYST.

Dr. L. S. McMurtry: I wish to exhibit a specimen of ovarian cyst, which is not of special interest excepting as a speci

men. Its walls as you will observe are very thin, and I deem myself fortunate in being able to remove it without rupture. The patient from whom this cyst was removed had suffered a miscarriage, and following it had an acute attack of pelvic peritonitis lasting for several weeks. The tumor was found in Douglas' space immediately to the left of the uterus. The left fallopian tube was found to be in a diseased condition, and was also removed. The tumor was but slightly adherent and was detached without difficulty.

Dr. W. C. Dugan: This case is very interesting to me owing to the fact that I operated upon one similar to it only a few days ago.

Dr. A. M. Vance: About a year ago in September I saw first a little boy about ten years of age, and diagnosticated suppurative disease of the hip. The case came under my treatment and ran a very rapid course. There was an abscess and evidences of excessive bone disease. The patient was put in the Children's Hospital three months ago, and the abscess opened and irrigated. At the time the abscess was opened, I spoke of there being very little tissue between the femoral artery and the abscess cavity, and we therefore used no drainage tube for fear sloughing would take place. The boy up to that time had been having a high fever. A few days after this I had a telephone message to come to the Hospital at once, that the patient was bleeding; I told the nurse to put her thumb on the artery at the pubic bone, and hold it until I could reach there. I found upon arrival at the hospital that the femoral artery had ruptured, the boy having lost a great quantity of blood. The vessel was tied by candle light and the limb wrapped in cotton wool and elevated. Gangrene however was present at the end of forty-eight hours and notwithstanding the patient's temperature was 104° and pulse beyond counting, amputation was decided upon. I think Dr. Guest remarked when the boy was on the table that the pulse was, according to his count 170 per minute; that is, he counted a quarter and it amounted to 170 for a minute. Dr. Dugan saw the case in consultation and we decided that there was about one chance in a thousand of saving the boy's life by amputation at the hip. This was done and the time consumed in the operation, from the time the patient was gotten ready until he was taken to another room after the dressings were applied, was about nine minutes.

The boy has about gotten well; I will state that the femur was very much involved, probably about four inches; the acetabulum was also involved; I did not take time to clean it hoping that nature would do so. I believe that if this patient had been kept on the table a few seconds longer he would have succumbed. The child would have died at the time of the hæmorrhage had the nurse not had the courage to have held the artery.

Dr. W. O. Roberts: I would like to ask Dr. Vance if there was any hæmorrhage at time of the operation.

Dr. A. M. Vance: There was very little hæmorrhage during the operation.

CASES OF BRAIN GROWTH.

Dr. W. Cheatham: I wish to simply mention that I have seen three cases of brain growth within two weeks. One case in which a woman had hemiopia; she discovered on waking in the morning that she could not see her child lying on her left arm. The left half of each field gone, the result of brain growth.

SUN-STROKE.

Dr. I. N. Bloom: At the Galt House about a week ago I was called to see one of the workmen who had been sun-struck. I took his temperature and found it registered 109°F. I have brought the thermometer here this evening to exhibit, and you will see it still registers 109°. I had the man wrapped in ice as I understand this to be the most rational treatment for sun-stroke, but the temperature never lowered and he died a short time afterward.

I also want to state that the case of scleroderma I exhibited at the meeting of this Society several months ago, remains exactly as it was at that time, except that all of the rose colored spots visible then have entirely disappeared. I see the case every month or so.

Dr. W. O. Roberts: I saw a case of sun-stroke several years ago which I reported in the *Medical News*. We attempted to take the temperature and the mercury went up to the top of the thermometer 112½° F. in about two minutes. It was a question as to how high it would have gone had the thermometer been longer.

Dr. J. G. Cecil: The report of Dr. Bloom's case calls to mind one that I have recently seen, an invalid child having spinal trouble, which developed into acute spinal meningitis. The temperature was taken on the third day of the acute illness and registered 108½° F.

The patient died on the third day of the illness.

CASES OF TYPHOID FEVER WITH VERY HIGH TEMPERATURE.

Dr. J. W. Irwin: Thirteen years ago I attended two cases of typhoid fever, a boy about nine years of age and a girl eleven, both had temperature of 109¼° F. It did not last long, however, in the boy two and a-half hours, and in the girl three hours. The elevation of temperature came on about the fourth week of the disease in both cases. It came on simultaneously; the children were both members of the same family, and sick at the same time. The heat of the body seemed to be so great that the muscles quivered like the quiver observed in beef after it is skinned. Both of the children recovered.

Concerning the suggestion made by Dr. Bloom, that ice is probably the most rational treatment of sun-stroke, I think Dr. Wood has pretty thoroughly established the fact that there is nothing equal to water. He prefers hydrant water at first to ice, and says it ought to be poured on in a continuous stream, and, furthermore, that it should be long continued, the ice chills too rapidly. There is great danger in reducing the temperature too quickly in cases of sun-stroke, owing to the partially coagulated state of the blood from the sudden heat. The sudden change in temperature by ice might cause death, while the application of cold water at first might be beneficial. I have seen a number of cases of sun stroke where the temperature was 107° and 108°, yet the patient recovered, but it was only after a great amount of perserverance. I have seen one case where the blood would not flow even though there had been made application of cold water. I think to be of benefit in these cases, the application of water should be continued for several hours after the patient has begun to improve.

Dr. L. S. McMurtry: I would like to ask, for information, if it is not true that in sun-stroke the blood will not coagulate at all, as it would do under other conditions. I have seen this statement somewhere.

Selected Formulæ.

THE TREATMENT OF LEUCORRHŒA.

The following solutions are recommended in the treatment of leucorrhœa by Gallois, according to the *Jour. de Médecin de Paris*:

℞ Sulphate of copper,.....gr. xv.
Water.....ʒ viii. M.
Sig.—Make a solution, and use as an injection in chronic leucorrhœa.

Prescribe at the same time ferruginous preparations, internally, and baths.

Another formula which is useful is:

℞ Salicylic acid.....gr. xc.
Glycerin.....ʒiv.
Water.....Oii. M.
Sig.—Dissolve the salicylic acid in the glycerin by the aid of heat, and add water.

This amount is used in six injections, one being given each day in vaginitis, due to irritation or inflammation about the uterus and vulva.

Still another formula is one containing:

℞ Chlorate of potassium.....ʒiv.
Wine of opium.....ʒiiss.
Tar-water.....Oi. M.
Sig.—Make a solution, and in a half a pint of hot water place two or three large tablespoonfuls of this solution, and, after mixing thoroughly, employ as an injection in fetid leucorrhœa.

As an astringent injection the following may be employed:

℞ Powdered catechu.
Powdered myrrh.....āā gr. lxxv.
Lime-water.....ʒxiii. M.
Sig.—Filter after prolonged maceration.

Give this injection several times a day, as long as the necessity continues, or the following may be employed:

℞ Chlorate of potassium.....ʒi to ʒiii.
Wine of opium.....ʒiiss.
Tar-water.....ʒviii. M.
Sig.—Make a solution, and add two or three dessertspoonfuls to a quart of hot water, employing as an injection night and morning, particularly in cases of leucorrhœa associated with endometritis, polyps, or fibroids. The duration of the injection should be about five to six minutes.

In cases of leucorrhœa or vulvitis, occuring in young girls in which there is no true vaginitis or metritis, the local treatment and the inflammation about the vulva is to be combated. This treatment is both local and general. The parts are to be washed carefully with astringent decoctions or with a weak solution of Goulard's extract. After this has been

done, the washing may be carried out by weak solutions of bichloride of mercury and by baths and lotions.

In other cases, carbolic acid, in the strength of 5 parts to 1000 of water, may be employed; and, finally, in obstinate cases, a solution of nitrate of silver, in the strength of 3 grains to the ounce, may be resorted to. In the intervals between the bathings, the parts are to be separated by lint impregnated with a weak solution of carbolic acid, or covered with red precipitate ointment. The internal medication consists in the use of cod-liver oil with quinine, or, in scrofulous children, the use of arsenical preparations. In place of these lotions, leucorrhœa may be treated by powders, such as the following:

℞ Powdered starch.....ʒii.
Subnitrate of bismuth.....ʒiiss.
Sig.—Mix very thoroughly, and dust the vagina with this powder.

In cases where good results do not follow the use of starch, powdered acetate of lead or tannin may be used, provided care is taken that they are pure. Frequently this treatment is useful after the the injections above named have been employed. With this treatment the following prescription in given internally:

℞ Powdered sulphate of iron.....ʒii.
Subcarbonate of iron.....ʒiii.
Powdered red cinchona bark.....ʒi.
Pulverized cinnamon.....ʒi.
Ergotine.....ʒi.

A small pinch of this powder may be given with the principal meals, and is particularly useful at the approach of the menstrual epochs. Prolonged injections, morning and night, of cold water, to which has been added a little vinegar, may also be advisable

In cases of gonorrhœal vaginitis the discharge may be stopped by the following:

℞ Tannic acid.....ʒvii.
Water.....ʒiv. M.
Sig.—Make a solution, and by the aid of the speculum introduce two tampons saturated with this solution.

If needed, a third tampon may be inserted. After twenty-four hours these tampons may be removed and cleansing injections employed, after which other tampons may be employed. Rest in bed is to be strenuously advised.

In other cases a solution made up as follows will be equally advantageous:

℞ Carbolic acid.....gr. xv.
Alcohol or cologne.....ʒi.
Water.....ʒiiss.
Sig.—Mix, and by the aid of the speculum once or twice a day insert tampons wet in this solution and practice astringent injections.

Sometimes it will be found necessary to use other tampons in place of those wet with alcohol and carbolic acid, particularly if a detergent influence is required, such as follows:

℞ Tannic acid.....gr. ss.
Pure glycerin.....ʒiii.

It is worthy of notice that in vaginal injections in cases of leucorrhœa it is necessary to employ large quantities of liquid.—*Ther. Gazette.*

REMOVAL OF A CALCULUS FROM THE VERMIFORM APPENDIX; RECOVERY.

Pinnock reports (*Australian Med. Jour.*, vol. xiv. No. 1) the case of a man, aged nineteen years, who was suffering from the usual symptoms of perityphlitis. Belladonna was applied externally and administered internally, and under this treatment the patient improved for some days, but became worse again, having obstinate constipation and vomiting matter with a fæcal odor. An exploratory operation was decided upon. This was done seventeen days after the beginning of the illness. The incision was made in the linea-alba large enough to admit the hand. Numerous adhesions were encountered, and a small cupful of pus and a quantity of fæces were evacuated. The vermiform appendix was found bound down by adhesions. It was found to contain a calculus, which was removed. A glass drainage-tube was inserted, and the wound closed with deep silver-wire and superficial horse-hair sutures. At the end of fifty hours a rubber tube was substituted for the glass one.

The calculus weighed fourteen grains, measuring half an inch in diameter and six-sixteenths of an inch in thickness. It was formed of phosphate of lime, and was arranged in concentric layers.

Reference is made to two similar cases, recorded by other observers.

Of 125 cases of ulceration of the appendix examined by Fenwick, a concretion, mass of fæces, or other foreign body was found in but fifty-five. In forty-seven of these, twenty-eight were concretions, fourteen hardened fæces, and five seeds or shell. In 200 dissections, Ferguson, of Toronto, found foreign bodies in the appendix fifteen times.—*Amer. Jour. Med. Sci.*

THE

MEDICAL and SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

DIRECT COMMUNICATIONS TO

P. O. Box 843, Philadelphia, Pa.

EDWARD T. REICHERT, M. D., Editor.

(Professor of Physiology, University of Penna.)

BUSINESS OFFICES:

29 to 35 North Tenth Street, Cor. Filbert.

EDITORIAL OFFICE:

Southeast Cor. 36th and Woodland Ave.

TERMS: Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00

REMITTANCES should be made payable to THE MEDICAL AND SURGICAL REPORTER, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

Pocket Record and Visiting List.

Two sizes. Prices to Subscribers of THE REPORTER.
For 30 patients a week (with or without dates)....$1.00
For 60 patients a week (without dates)..... 1.25
Prices to non-subscribers, $1.25 and $1.50 respectively.

The Model Ledger.

Physicians who keep their own books will find this of great value. It enables the Physician to make out his bills with great ease and gives at a glance the amount earned, received and due in any quarter. Sample pages sent on application. Price, $5.00.

Binders.

Patent binders for the Reporter, each lettered on the back in gilt "**The Medical and Surgical Reporter**" and made to hold the issues of six months. Price, 50 cents.

Vaccine Matter.

Bovine Crusts.....$1.50 each.
Bovine Points or Quills..... 1.00 a doz.
Humanized Crusts..... 1.00 small.
Humanized Crusts..... 2.00 large.
Guaranteed in every respect.

Books.

Books will be supplied to our subscribers, transportation prepaid, at the regular prices.

☞Please accompany orders with the money, and address all communications to

Leading Articles.

ANNOUNCEMENT.

Owing to the increasing pressure of other work, Dr. Reichert finds it necessary to discontinue his editorial connection with the REPORTER. He desires to express his hearty thanks to the readers of the REPORTER for the many manifestations of their appreciation of his efforts to improve the journal and for their invaluable co-operation.

THE THERAPY OF DIPHTHERIA.

In a comparatively recent number of the REPORTER, in an article on the subject of blood-letting in pneumonia, that praiseworthy and veteran investigator, Dr. Hiram Corson, made use of the following remark, "Experience is a harmful thing as a reason for continuing to practice a certain course, unless it has been successful experience." We certainly agree with Dr. Corson.

The average practitioner, especially if he cannot or will not take the time for new and original researches, is very prone to fall into a certain rut, out of which it is almost impossible to remove him. Nearly every physician of this class has his favorite cough mixture, his favorite prescription for diarrhœa, etc., and as years roll on and newer and more efficient drugs appear upon the market, we find him still plodding along in the old path which is "good enough" for him, and meeting many failures as well as occasional successes with stoical resignation. His "experiences" lay in one direction, and he would not deign to adopt another course.

Not very long ago, a physician is said to have asked a colleague for a good remedy for catarrh—it was cheerfuly given. "But how do you know it is good," was asked, "have you had any experience with it?" "Why certainly," was the prompt reply, "I have had catarrh

for the last ten years myself, and have used nothing else."

This sort of "experience," is, however, not confined to the busy practitioner who lives a decade or so back, as far as his practice of medicine is concerned, but many able and thinking men fall into similar ruts, and stay there until they are literally hurled out by the flood of new and improved ideas that are forced upon them.

We need not go far for examples—one of the most eminent surgeons of the day, a man whose profound knowledge and exhaustive writings are recognized the world over, was years before finally embracing, even in a measure, the principles of antisepsis. His "experience" was in another direction, and hence the difficulty.

We must thank Löffler for having demonstrated the biological, morphological and pathogenic properties of a bacillus which has been proven to be the exciting cause of a number of diphtheritic diseases. In other cases this bacillus is not found, but bacteriological examination reveals the presence of the streptococcus as the exciting factor.

The severity and course of this disease is largely dependant upon the exciting microbe. The clinical picture, however, which meets our view when either of these germs are present is so similar in the first stages of their growth, that the differential diagnosis can only be definitely determined by a careful bacteriological examination.

If we class under the name "diphtheria" only that condition so dreaded where the choking of the child is imminent, then only Löffler's bacillus can be regarded as the ætiological factor. The symptomatic picture is such that we cannot but agree with Löffler in speaking of this form of the disease as the "true diphtheria" in opposition to the variety caused by the streptococcus. The latter Löffler speaks of us as "pseudo-diphtheria."

Both affections differ materially in their reaction towards various therapeutic measures. It has been the pseudo- or streptococcus diphtheria that has afforded us so many purported cures for diphtheria.

In the beginning of the diseases, as has been said, it is frequently difficult, and often impossible to clinically differentiate the two forms, only a bacteriological culture will do this. An apparently harmless process, confined entirely to the tonsils, and primarily only accompanied by a slight elevation of temperature, and with but little alteration in the patient's general condition, may develop within twenty-four to forty-eight hours into a severe case of true diphtheria; while, on the contrary, a process which at the outset is apparently most acute, may prove itself to be caused by the streptococcus and be easily cured by therapeutic measures.

Arguing from the fact that where guinea-pigs are inoculated with the bacillus of diphtheria, in spite of the severe pathological changes of the kidneys and pleural cavities, no bacilli are found in the internal organs, Löffler has concluded that these bacilli must produce a poison which is most deleterious to the organism. He has been able to isolate this poison, and his discovery has since been confirmed by Roux and Jersin as well as Kolisko and Paltauf. Later Brieger and C. Fränkel have shown that this poisonous substance belongs to the albuminoids. This substance prominent for its poisonous properties, undoubtedly plays a most important part in diphtheria.

While the bacilli of diphtheria seldom enter the circulation, yet through their growth in the fauces and thereabouts they open a way of entrance to the blood-vessels for other microörganisms, especially streptococci, by means of the necrosis of the epithelium which they produce, and these in turn increase in the organism, and tend to greatly complicate the disease.

The successful therapy of diphtheria

must answer three distinct requirements. First, it must directly influence the life of the bacilli and check their growth. In doing this it also prevents a further formation of the poison they produce. Second, it must check the action of the poison already absorbed into the system. Third, it must prevent the invasion of other micro-organisms, or if already present, destroy them. According to Professor Strübing, of Leipwald, in an article on this subject in the *Duetsche Medicinische Wochenschrift*, these ideal requirements can be realized by the use of a combined local and general treatment of the disease.

We, however, know of no remedy which will with certainty annul the action of the diphtheritic poison in the system. We are equally uncertain of being able to destroy other micro-organisms which have been absorbed. We must, therefore, strive to check the development of the diphtheritic bacillus, and to prevent the invasion of other germs. In a patient, however, who has for some time been under the influence of the diphtheritic poison, it cannot be expected to gain as much by any local treatment as when the disease is taken at its first appearance. In favorable cases we can succeed by local treatment in closing the doors against these enemies of the human organism, but the success of such a treatment depends upon the earliness with which the treatment is instituted. The vast importance, therefore, of the early diagnosis of diphtheria cannot be over-estimated.

Apart from this, in the more advanced cases, the substances generally used in the local treatment must, to occasion any benefit, be used in such quantities as endanger poisoning. It has been said by some that all local treatment is worthless, since the diphtheritic membrane continues to form anew. This new formation is, however, caused by an internal process of the disease.

The diphtheritic disease of the mucous membrane first causes necrosis of the epithelium, and then an alteration of the vessels of the mucous membrane, the latter then discharge a fluid exudate, which forms the false membrane. This formation of pseudo-membrane continues after the death of the bacilli, and as long as any of the previously formed poison remains in the mucous membranes. Not until the change of the vessels of the mucous membrane has disappeared and the epithelium again becomes normal does the formation of false membrane cease.

If these membranes are removed mechanically, one must be careful not to leave the wound thus caused in a condition which might facilitate the ingress of other micro-organisms; that is to say, one must keep the mucous membrane of the throat constantly under the influence of substances which will antagonize such germs. The removal of the false-membrane is, however, not an absolutely necessary measure, since the bacilli are usually in the upper layer of the membrane, and substances locally applied easily penetrate it. The chances for recovery are better the thinner, that is the younger, the membrane.

Upon these principles Strübing has instituted a treatment which he has applied to a whole series of cases. For the local treatment he has used alternately applications of iodo-phenol and liquor of sesquichloride of iron and sulphur. Apart from this, the mouth was kept clear by constant gargling. For the gargle diluted lime-water was used. When the subject was too young to use a gargle, inhalations were used in its place.

For the internal treatment the following was used:

℞ Hydragyr. cyanat..... 0.01 gram.
Aquæ dest.....100.00 grams.
Sig.—One teaspoonful every hour.

On the strength of Löffler's experiments the following mixture was applied to diphtheritic patches every 4, 6 or 8 hours:

℞ Acid carbolic..... 3–5 grams.
Ol. terebinth..... .40 "
Alcohol absol..... .....60 "

Aside from this the following mixture was used as a gargle in suitable cases:

℞ Acid carbolic..... 3 grams.
Alcohol.....30 "
Aquæ distil.....70 "

The danger of poisoning should be guarded against by a careful watching of the urine. As soon as the liquor sesquichloride of iron causes an intense reaction of the urine, the carbolic acid should be stopped

In other cases local mercurial treatment was also instituted. Solutions of 1: 1000 of the bichloride being applied locally, and a 1: 10,000 solution of the bichloride or cyanide used as a gargle.

The mercurial treatment seemed to have certain decided advantages over all others in true diphtheria, although the carbolic treatment was most efficient. A series of bacteriological experiments by Löffler. have shown that the latter treatment acts well upon the diphtheritic progress.

As has been mentioned, recent cases offer greater chances for recovery than those of longer standing. Even when it becomes possible to check the local process, the secondary changes in the organism frequently cause death, especially in cardiac affections.

The results obtainable are equally as unfavorable if the air passages become affected. In favorable cases timely tracheotomy may sometimes prevent stenosis of the larynx, and some times inhalations of lime water, papoid, lactic acid, etc., may cause a loosening of the false membrane.

Those cases which we clinically diagnose as diphtheria, and yet belong to the class of pseudo-diphtherias, distinguish themselves by their lighter course and greater susceptibility to treatment. When treated as true diphtheria, Strübing has found that this form is most satisfactory to treat.

Scarlet diphtheria, or diptheritic scarlet fever, Löffler has found to be due to the action of streptococci. Here the carbolic acid treatment proved to be the most efficient. If the process extends over the entire fauces and nares, and the streptococci have been absorbed into the blood in large quantities, then the patients become "septic," and it is only a happy chance if they recover. If in such cases the local processes have been checked, our attention should be turned to the heart's action, but even the most active treatment is frequently unavailing.

The prophylactic treatment, consisting of gargling or applications of carbolic acid solutions, is recommendable in all cases of scarlet fever.

In conclusion we would say that Strübing's treatment is based upon sound principles, and, more than this, has been proven to be of great value.

THE THERAPEUTIC VALUE OF SUPPURATION.

Vochier having observed improvement in cases of puerperal septicæmia, taking place coincidently with the appearance of a focus of suppuration in some part of the body, suggested that in certain cases the establishment of suppuration by the subcutaneous injection of turpentine might be of therapeutic value. Later a case of pneumonia was reported by Lepine, in which this method appeared to have been of great benefit. A case has recently been reported by Gingeot. A man twenty-nine years of ags, of alcoholic history, suffering from acute pneumonia, received on the ninth day subcutaneous injections of turpentine into the four limbs. At the time his condition was very critical. The injections were very painful and were followed by extensive œdematous patches, and later by suppuration. Within two hours of the first injection the temperature fell two degrees, and this was followed by subsequent improvement. The patient ultimately recovered. A similar case is reported by Raoul in which a patient, apparently moribund on the sixth day, was apparently cured by similar treatment. The explanation of the improvement given by Gingeot is that the production of artificial abscesses, by setting up leucocytosis, brings up reinforcements of phagocytes, as it were, to the assistance of the original defenders.—*Bost. Med. Surg. Jour.*

Book Reviews.

A NEW PRONOUNCING DICTIONARY OF MEDICINE. Being a Voluminous and Exhaustive Hand-Book of Medical and Scientific Terminology, with Phonetic Pronounciation, Accentuation, Etymology, etc. By John M. Keating, M. D., LL. D., Fellow of the College of Physicians, of Philadelphia, etc., and Henry Hamilton, author of a Translation of Virgil's Æneid into English Rhyme, etc., with the collaboration of J. Chalmers DaCosta, M. D., and Frederick A. Packard, M. D. With an Appendix. Philadelphia: W. B. Saunders, 1892. Price, Cloth $5 net; Sheep, $6 net.

This work of nearly a thousand pages octavo gives besides the dictionary proper a considerable amount of matter in the form of an appendix which will prove of every-day usefulness to the physician and student. Like most of its class it does not call for an extended review. Regarding the number of words, it seems sufficiently full—many new words have been added and those obsolete omitted. The definitions are usually crisp and satisfactory, but occasionally we notice a bad slip, as for instance "Catamenia. Applied to the monthly discharge of blood from the ovaries." The question of pronounciation received careful study, the matter seeming to depend entirely as to whether or not Greco-Latin medical terminology should be accepted and incorporated *en masse* as a part of the English language, and they wisely decided to follow the custom of the majority of English-speaking physicians and largely adopt an anglicized pronounciation without hard and fast rules. In connection with accentuation, they have closely followed the rules laid down in Worcester's unabridged.

In the appendix, which occupies nearly hundred pages, we find tables of weights and measures and metric weights and measures;of the equivalents in Centigrade and Fahrenheit scales; table for calculating the period of utero-gestation; diamaters of the female pelvis and fœtal head; table of cardiac murmurs; diagrams of distribution of the cervical, brachial, lumbar and sacral plexuses; table of the cranial nerves; table of the localization of the functions of the segments of the spinal cord; table of the chief characteristics of the principal bacteria; table of leucomaines and ptomaines; table of the number of props of different liquids required to comdose a fluid drachm; dose table; list of incompatibles; table of poisons with an account of the general symptoms, modes of death, antidotes and general treatment; list of the newer drugs and their solubilities, doses, etc., diagrams of the motor nerve-points, synonyms of diseases, symptoms, signs, etc., designated by proper names, formulæ of standard solutions; drugs and materials used in antiseptic surgery, together with general directions concerning preparations for antiseptic operations.

The book has been printed with new, clear and handsome type on excellent paper. It is alike creditable to authors and publisher and is deserving of the highest recommendation.

ELEMENTS OF MATERIA MEDICA AND THERAPEUTICS, INCLUDING THE WHOLE OF THE REMEDIES OF THE BRITISH PHARMACOPŒIA OF 1885 AND ITS APPENDIX OF 1890. By C E. Armand Semple, B. A., M. B. Cantab, M. R. C. P., Lond. With 400 illustrations. London and New York: Longmans, Green & Co.

In writing this book the author has confined himself to the drugs which are officinal in the British Pharmacopœia of 1885 and the Appendix of 1890. The work is divided into two sections, the first dealing with inorganic substances, including alcohol, etherial preparations, etc., and the second with vegetable and animal products. But little attention has been given to pharmaceutical detail, the reader being refered to the author's "Aids to Pharmacy." Illustrations are quite numerous and are generally satisfactory; some are quaint and others entirely superfluous. The text is necessarily concise, and as a whole is good.

As a book for the American student it cannot prove of much value, owing to the fact of its not being adapted to our Pharmacopœia.

CARBOLIC ACID POISONING IN A HOSPITAL.

A patient in a London hospital recently died from poisoning under peculiar circumstances. A sister-in-law who had come to visit her gave her to drink from a basin standing on a table near the bed. The basin was thought by the visitor to be filled with water, but actually contained a carbolic acid solution.

Correspondence.

REPLY FROM DR. PHELPS TO DR. SAYRE'S LETTER IN THE ISSUE OF AUGUST 27TH.

To the editor of THE MEDICAL AND SURGICAL REPORTER:—My attention has been called, by Dr. L. A. Sayre, to an article which appeared in your paper on July 9th '92. The article in question is, presumably, a stenographic report of a clinical lecture delivered by me to the class at the N. Y. Post Graduate School and Hospital, some time during the past spring. I also received, by this mail, a copy of the REPORTER of August the 27th, '92, in which I find an article, written by Dr. Sayre, headed "Dr. Phelps Misquotes Dr. Sayre." I enclose to you the following correspondence, which will explain itself:

285 FIFTH AVENUE,
Aug, 11th '92,

My dear Dr. Phelps:—

Reginald has just received a large number of slips on Orthopædic Surgery from Sajou (5) for review. And among them a slip from the Philadelphia REPORTER, of July 9th, '92, containing a lecture by you in which you refer to the Morehead Case of Anchylosis from confinement, and say that all the other joints were anchylosed but strange to say the hip-joint that was diseased was *not anchylosed.* And yet you pretend [to] quote from my Book to prove your statement. How you could possibly make this positive misstatement which is directly the reverse of what is published in my Book, I cannot understand, and wish very much that you would explain it.

Yours truly,
LEWIS A. SAYRE.

REPRODUCTION, FROM MEMORY, OF MY LETTER TO DR. SAYRE.

HOTEL CHAMPLAIN.
Lake Champlain.

Dear Dr. Sayre:

Your letter, of August the 11th, is received, having been forwarded me here. In answer I will say that I was not aware that any lecture of mine had been published in any Philadelphia paper. Any error that may have appeared, however, I will gladly correct. I will call at your office as soon as I return.

Very sincerely,
A. M. PHELPS.

Dr. Sayre accuses me, in both his letter and article, of having wilfully misquoted him from his book. This I have never intentionally done. And any error that may have arisen, either through myself or the stenographer, I assured him in my letter I would be more than willing to correct. Dr. Sayre did not give me the opportunity of even examining the lecture of July the 9th, to which he referred, but immediately addressed an article to the REPORTER accusing me of malicious mis-representation. It would only have been ethical, not to say fair, for Dr. Sayre to have afforded me an opportunity to examine the lecture mentioned, and then write a personal letter to your paper correcting any error that may have crept in. If I hurriedly rushed into the journals with a sensational letter whenever my articles have been misquoted, and my work appropriated by others, without due credit, I would have but little else to occupy me. If an error has presented itself in the lecture attributed to me I am certainly very sorry.

I am, very sincerely,
A. M. PHELPS.

CORRECTIONS OF DR. DAWBARN'S LECTURE IN THE ISSUE OF AUGUST 6TH.

To the Editor of THE MEDICAL AND SURGICAL REPORTER:—I am just in receipt of the copies of your August number, kindly sent, as I have been away from town until now, and have read the report of my clinical lecture published therein. I have frequently admired the grace and appreciated the courtesy with which medical reporters have edited, emended and improved upon my disjointed clinical utterances made generally during operations before a class. The sentences glide smoothly and acquire a polish originally denied them.

This article is no exception to the rule, and I beg you to convey to the gentleman in question in this instance my thanks and my compliments. It is inevitable that under such circumstances—the speaker not having the opportunity to correct proof—occasional errors as to what he

said, or perhaps meant to say but through a possible form of aphasia failed clearly to express—should creep in. I will therefore appreciate the kindness if you will publish the following few corrections:

A propos of intussusception: "The patient was inverted, and nearly two quarts of glycerine introduced into the rectum with a fountain syringe, and the patient kept in that position for half an hour. At the end of that time there was a remarkably copious discharge of fæces, and the obstruction was completely relieved." Here, obviously, the statement should be added, that the patient while in the Trendelenberg posture was under anæsthesia.

"In both volvulus and intussception, the best treatment in my judgment is to cut out the affected portion and make an artificial anus, and a few weeks later operate for the restoration of the continuity of the gut, preferably by intestinal anastomosis."

No surgeon (medicine having failed) would think of taking this severe and dangerous step if on opening the abdomen the obstruction could be reduced without great violence, and if the parts be found not gangrenous. Otherwise, nothing but the excision and subsequent restoration of continuity remain, preferably by (lateral) anastomosis.

—"But on applying a match to one of the perforations in the intestine, there was a violent explosion"—etc. In this discussion of Senn's method with hydrogen gas, the statement should of course be that the match was held near the wound in the abdominal wall; not the gut. By-the-bye, if a cup be placed over the wound to catch the gas, and this, still inverted, be removed to some distance and then lighted, danger of explosion is thereby removed. Better still is my suggestion of using oxygen gas instead of hydrogen, for every reason. It is much more readily obtainable and can be used direct from the canister; it it is a systemic stimulant; is easily absorbed into the blood and recovered; and is non-explosive. A lighted match held in it burns with electric brilliancy, however—which is the test. For reasons roughly outlined in the lecture as printed by you, nevertheless the gas-test is not to be regarded as of much value, and it is even an element of danger in some cases. "—It is only very lately that we have learned that the appendix is not an intraperitoneal viscus." Instead, here read "learned that the *cæcum is* an entirely intraperitoneal viscus."

Again—"This point (that of greatest tenderness in appendicitis) is supposed to be about opposite the *apex* of the appendix, and hence it is mid-point of the incision."

For *apex* read *base* of the appendix—a difference, it is obvious, of four to six inches.

In discussing the technique of the operation for appendicitis I have described a plan of my own (heretofore published) for overcoming by *postural* treatment during the operation, the frequent annoyance caused by the slippery small intestines falling over and in front of the cæcum and appendix. In your report I am made to say—"Turn the patient over so that he rests with the left side against the bed or table, and the field of operation is uppermost; then seize *the edge of the gut* in the abdominal opening with a retractor, and draw it forward away from the spine. This will make a cavity into which the small intestines will fall out of the way, while the cæcum which has a very short mesentery cannot follow, but must remain uppermost."

For the edge of the *gut* read the edge of *cut*: that is, the cut abdominal wall. Also, precede the word *intestines*, by *small*.

"The mucous membrane and the stump of the appendix should be scraped with a spoon, and the stump disinfected," etc. Here read for *spoon*, a smallest sized *Volkmann's sharp spoon*.

This number of corrections, and most of them important ones, might I fear cause a casual reader to think the report of my lecture as a whole a very inaccurate one; which would be far from the truth. The report made quite a long article, containing a considerable number of statements, and almost all were correctly reported—much more so than the average.

Very respectfully yours,

Robert H. M. Dawbarn, M. D.
105 West 74th Street, New York.

VESICATION IN INCONTINENCE OF URINE.

Swan (*British Medical Journal*) advises vesication of the nape of the neck as a successful treatment in incontinence of the urine.

Periscope.

THERAPEUTICS.

FEL BOVIS IN TYPHOID FEVER.

Dr. Adolph Zeh, in a lengthy article appearing in *Merck's Bulletin*, gives the treatment in detail of ten cases of typhoid fever in which fel bovis in 3 grain doses, three times a day, was the main reliance, and all the patients recovered. He states that among some personal friends there were forty-eight more cases treated in the same method and not a single fatality. To those interested we commend the reading of the entire paper, which is far too lengthy to reproduce.

TREATMENT OF PNEUMONIA.

From an extensive study of the mortality of pneumonia under different modes of treatment, Reed (*Therapeutic Gazette*, Nos. 3 and 4, 1892) concludes that water, locally applied, either as the wet-pack or as the bath after the method of Brand, is the most efficient single therapeutic measure for acute pneumonia. In the first stage of the disease, veratrum viride or aconite can accomplish more than any other drug; and in the second stage the same is true of digitalis. A combination of one of these cardiac sedatives with opium and diaphoretics constitutes a safe and successful internal treatment in the first stage, being capable of aborting the disease if the administration is begun near the onset and is repeated at short intervals, day and night. Venesection, though a most efficient procedure in the treatment of pneumonia of sthenic type and, judiciously employed, considerably more successful than expectant measures, is no longer an indispensable resource in managing the disease, as other remedies have been found to accomplish the same results more surely and more pleasantly.—*News.*

A THERAPEUTIC NOTE ON ALOPECIA AREATA.

Dr. L. Duncan Bulkley claims that 95 per cent. carbolic acid applied in small areas of denuded hair surface will facilitate the new growth of hair quicker than any other medicine. He applies it by a small cotton swab on areas no larger than two square inches at one time, and rubs the acid well into the tissues. The treatments are given no oftener than once in two weeks on the same patch.—*Journal Cutaneous and Genito-Urinary Diseases*, February, 1892.

MEDICINE.

THE RELATIONS OF THE BRONCHI TO THE POSTERIOR WALL OF THE THORAX.

Bianchi and Cocchi examined twenty-one bodies, with the following results: They find that the trachea divides opposite the body of the fifth dorsal vertebra, and that its lower end is somewhat to the right of the middle line. They state that the right primary bronchus, which descends more obliquely than the left one, corresponds to the fifth intercostal space. The left primary one runs parallel to the sixth rib. The area occupied by the great and medium bronchial tubes extends vertically from the fourth intercostal space or the third rib, to the eighth space, and laterally to four or five centimetres from the line of the spinous processes.

THE RELATION OF VARICOCELE TO NEURASTHENIA.

Wiederhold (*Deutsche med. Wochenschrift*, 1891, No. 37.) believes that in many cases of hysteria with supposed ovarian symptoms the trouble is really due to dilatation of the veins forming the spermatic plexus, and that if any operation is performed ligation of these veins is preferable to castration, providing that the ovary is not much diseased.

FÆCAL VOMITING AND NEUROSES.

Dr. Desnos reports (*La Tribune Med.*, Dec. 3) the case of a youth found unconscious on the highway. He had escaped from a criminal insane hospital. He had epileptiform attacks, but exhibited hysterical stigmata. During several attacks fæcal vomiting occurred. He stated that for two years he had never passed fæces otherwise. The vomitings were fæcal in character and contained no traces of food. They had preserved the mould of intestine. The patient was seen during the attacks. At the time of vomiting he complained of enteralgia and the abdomen became tympanitic. These vomitings had obtained after traumatism producing cicat-

rization of the anal region. Dr. Labbé had seen an hysteric whose enemata were passed by the mouth. Dr. Legendre said that the duration in the first case was exceptional. He had seen similar cases in hysterics. The pathogeny was antiperistaltic movement from the large intestine to the mouth. Dr. Matthieu called attention to the fact Cherchewski (*Revue de Med.*, 1885) had, several years ago, called attention to neurosis attended by tympanitic distension of the abdomen and fæcal vomiting.

SURGERY.

EPITHELIOMA.

At the Vienna Gesellschaft, Eiselburg showed a case of a man, æt. 58, who thirty-five years ago had a pustule on the parasternal line that was rubbed off, forming a sore. Twenty years ago it was about the size of two kreuzers, at the present time twice the area of the palm of the hand. The site is unusual. He related two others that had come under his notice, one on the deltoid, another on the upper part of the arm, after a burn he had had when seven years of age.

ABSCESSES IN POTT'S DISEASE.

Dr. Burrell believes the following conclusions are warranted: 1. That efficient mechanical support of the spine is the prime factor in the treatment of caries of the spine associated with an abscess. 2. That under an expectant plan of treatment the abscess will, in many cases, disappear. 3. That the indication for operative interference is a steady or rapid decline in the patient's general condition. 4. That the operation should consist in thorough evacuation of the abscess, and the establishment of drainage from as near the seat of the disease as is practicable.—*Archives of Pediatrics*, May, 1892.

ON THE TORSION OF ARTERIES.

In connection with operations for excision of tumors, and other excisions of a like character, Jonathan Hutchison remarks as follows: "I may mention that for many years I have quite ceased to use any other means for arrest of arterial bleeding than torsion. In excision of the breast, for instance, I do not think that I have during the last fifteen years ever used a ligature. The torsion is always effected by a pair of Well's clamp forceps, now in such universal employment. I am always extremely careful to close all the vessels, keeping the wound exposed for a considerable time for that purpose. Very seldom, indeed, have I encountered any secondary hæmorrhage."—*Archives of Surgery.*

OBSTETRICS.

INFLUENCE OF MACERATED FŒTUS ON CHILDBED.

Swiecicki (*Nouv. Arch. d'Obstét. et de Gynéc.*, March 25th, 1892, Supplement, p. 137) finds that in 247 cases of macerated fœtus, childbed was perfectly normal in 157 cases, even when fœtid gases and stinking liquor amnii were expelled from the uterus. In seventeen cases inflamed breasts occurred, without suppuration; in seven *post-partum* hæmorrhage with rise of temperature; and in seven temporary œdema of the vulva. In fifty-two cases there was rise of temperature during the puerperium without appreciable cause; it appears that syphilitic women are subject to such rises in childbed. This must be due, Swiecicki thinks, to external infection; the macerated fœtus cannot infect until air has entered the uterus. In six cases slight parametritis occurred. Only one of the 247 died, and in this instance pleuro-pneumonia and nephritis existed before labor. Labor usually takes place about the seventh month, but neither the maceration of the fœtus nor its extraction at delivery appears to have any distinctly bad influence on childbed.—*Brit. Med. Jour.*

PROTECTION OF THE PERINEUM.

Dr. William S. Gardner (*Journal of Gynæcology and Obstetrics*) writes that the value of a complete perineum is so great that the gynœcologist spends much time in inventing new methods for its repair. What he has to offer on this subject is only the method of applying the principle that time is the great perineal protector, bearing in mind that almost any perineum will distend sufficiently to allow the safe passage of the head, if only the head can be prevented from advancing with too great rapidity

just during the last portion of the second stage of labor. The two great forces driving the child toward the outer world are the contractions of the uterus and the contractions of the abdominal muscles. There comes a time in the labor when the perineum becomes so weakened by distention that it can no longer bear the great pressure of these combined forces, a time when a few minutes' delay means the prevention of a rupture. Uterine action is beyond our control; the contraction of the abdominal muscles can be controlled either by complete anæsthesia or by the will of the patient. She is instructed in the interval between the pains that when she feels a pain coming on she is at once to open her mouth and breathe through it as rapidly as possible. In addition the the head is held back by pressing against the perineum in the direction of the pubes. The perineum should be as carefully guarded during the passage of the shoulders as during the delivery of the head.

GYNECOLOGY.

LIPOMA AND FIBROMA OF THE FALLOPIAN TUBE.

Parona (*Ann. di Obtet. e Gin.*, 1892, No. 2) in removing the adnexa for the cure of uterine fibro-myoma, encountered a lipoma the size of a pear, from which was pendent a normal ovary. The tube was so imbedded in the tumor that only the fimbriated end was visible. It apparently developed from one of the fimbriæ.

Spaeth (*Zeitschrift für Geb. u Gyn.*, Bd. xxii., Heft 2) reports the case of a patient from whom he removed a tube which contained a true interstitial fibromyoma imbedded in its wall at a short distance from the uterine end. There were no evidences of chronic inflammation in the tube, so that it could not have been a case of so-called pachysalpingitis.

SALICINE FOR PELVIC PAIN.

Cheron (*Med. News*) states that in pelvic pain during the course of metritis or salpingo-ovaritis as well as in pelvic cellulitis and peritonitis particularly if these troubles are associated with rheumatism, that salicine is of value. In those women who after the menopause, have uterine pain and discomfort in the lumbar or sacral region, with occasional flushes of heat and neuralgic dartings, a careful interrogation as to any history of rheumatism should be sought for, and if this disease is found to be present, salicine is administered. The dose which he ordinarily recommends is fifteen grains, to be divided into three parts. Very soon after the administered the pain decreases. Cheron generally directs that one drachm of salicine be divided into twelve capsules. One of these capsules may be given morning, noon and night, the patient taking a glass of water at the same time to prevent irritation of the stomach.—*Arch. of Gyn.*

NEWS AND MISCELLANY.

THE DOCTOR AS A DEBTOR.

There is a good deal said in medical journals about the doctor's bills and the hard time he has to collect them. It seems that there are doctors who are debtors, and who are not very responsive to just monetary claims upon them. We are rather glad that the Cleveland boy, as narrated below, got the best of his debtor. The boy in question had as a customer a certain South Side doctor. When the physician's bill reached $1 the boy presented it. It was hard to collect. The boy called several times, but the doctor never had the dollar. The physician moved away and the lad lost sight of him for a time, but finally located him on the West Side and renewed his attacks. At last one day he told his mother he would make one more effort, and then if that were not successful he would give up. Accordingly he went to the doctor's office and found the doctor out. But inside the door hung the customary slate. On it the boy wrote. "Call at——Street, William Smith." The doctor called and the boy saw him coming up the street. He told his mother what he had done, and said: "Now, I will hide, and you show him the bill." "I will do nothing of the kind, Willie Smith," said the lady, "and you ought to be ashamed of yourself." A young lady visitor in the family thought more of the scheme and, confronting the doctor at the door, presented the bill. The professional man said that the joke was on him, paid the dollar, and went away laughing.—*Medical Record.*

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & Co.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.

(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.

(WM. R WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.

(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not pro erly secreted. As a dinner pill, Pil Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.

(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica . . ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{250}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

SPECIALISM.

JOSEPH PRICE, M. D.,
PHILADELPHIA.

Literary and Academic societies are of early history. Societies for the promotion of knowledge or enlightenment in the line of specialties are a product of the nineteenth century. They are an outgrowth of a recognized necessity among students and scholars for the organization of society institutions for discussion, collection of facts and comparison of results. As we have advanced in knowledge, and the field of our labor has broadened in pace with it, these societies have increased in number and become more specialized. From the State organization of specialists we have the International Congress as a natural outgrowth. The chief advantage of societies of specialists is that they focus, systematize, investigations. The most modern and triumphant specialism is that of abdominal surgery. It has made recent signal advances. In only rare instances did the old surgeon venture to enter the abdominal cavity, while the surgeon of to-day enters with marvelous skill and success. Experience and careful experimental research by specialists have simplified methods and are rapidly doing away with timid manipulation. In this line the command of exactness has something of military certainty and emphasis in its sound. All the major cases in abdominal surgery come properly within the sphere of the specialist by their very nature. To deal with them successfully requires aptitude, special training, the power of rapid manipulation, precise and dextrous use of instruments. There may be some danger in so exaggerating our specialties as to make us lose a wise balance as physicians. The essential conditions of good work are a sound, enlightened judgment, accuracy of physiological knowledge, careful study of the causation of diseased conditions and of the best methods of applying our scientific knowledge to practical use. The respective fields of the specialist and general practitioner are not so widely separated that their several success is not dependent upon their study of the same conditions.

We do not find it difficult to separate the all-around-doctor from the specialist when we consider the definite field of the one and the broad, limitless field of the other. But we maintain that within the lines of our profession there are no successful specialists who have not had extended experience as general practitioners; whose best equipment, most valuable professional treasure, are the deep-bedded lessons of such experience. The recruits of the ranks of specialism, all those who have reached the high water-mark of success, whose names are written large come from the ranks of the general practitioners. Conditions keep them within the hoop of the same horizon. The one important lesson for both to learn is where the domain of medicine ends and that of surgery begins. In the lines of no one of

our specialties will a superficial training answer. The old practitioner with his vast general experience, his varied knowledge, his mastery of very many branches, his careful study of his work, and its results, his quickness to recognize the deviations from health in special organs, his knowledge of their relationship and influence on other organs preeminently fit him for some specialty if his taste and love for the work directs him that way. It should be carefully marked that taste and love for a special line of work is essential to success. In general practice every doctor has the conviction that there is some one thing in which he is better, more successful, than in another. And it is likely that his constituents, while they recognize his general ability, further recognize that he has a specialty; they speak of "our doctor" as being specially good in certain diseases. And in these diseases his neighborhood brothers of the profession call him in as consultant. These men are representative of the old school specialists. And we congratulate the profession that we still have some of them left. We rejoice that we still live in the midst of these old-fashioned practitioners. For in the terse words of a eulogy on a distinguished surgeon, "More than any men they have helped to make us gentlemen."

The new specialist is a mushroom growth,—he is an embryo product of our modern schools. He elects his specialty before he leaves college. After graduation he announces that he is to make nervous diseases a specialty, or he is going to be an oculist, a gynecologist or an obstetrician or at a bound he is going to be a laparotomist,—he will not bother with the minor details of gynecology but will walk straight into abdominal surgery. Or it may be that in his aspiring he may want to climb into ethereal regions and he selects electricity as his specialty. It is a gratification to know that the specialists from the ranks of the old school practitioners stay on the earth and have their offices on the ground floor. These new specialists aspire to do work without giving due consideration to the special and general qualifications essential to its successful performance. These incipient specialists do mischief, are more hurtful to the general profession than to themselves. They are but small items in the account, yet with all there is no danger of the highway of specialism becoming crowded,—along it only the fittest can survive. There is no element of the saint in disease and often it takes the most trained intellect and hands and a high courage to deal with it. He can only prove himself fit for the specialty he professes by what he knows and by the sequal of what he does. The experienced mechanic does with his eye that for which the apprentice requires a foot-rule; the specialist's work must be something of a worship, he must be ever seeking new revelations, unpublished facts.

Too largely does a purely business or mercenary element enter into the motives of the new specialists. The ambition, not altogether American and very human, to "get rich quick" is the predominant incentive with many. Large fees fill the imagination and distort the vision. It should be remembered that to command large fees is first to become preeminently expert. The specialist and the general practitioner meet on common ground each aiding in educating the other, each contributing the materials of their general or special knowledge to the building up of an accurate and comprehensive medical science. All of us must sometime feel that we have met with a trouble with which we cannot successfully deal and that we must summon the aid of one who has made the trouble a special study.

Our medical and surgical literature—old and new—bear witness to growth through many generations. The earlier

history of surgery is chiefly that of battle fields, the dealing with spear- and arrow-head wounds, and many of its advances were due to new forms of wounds inflicted by new instruments of warfare. Though our modern surgical practice is founded on a scientific basis, many valued lessons in operative procedure come from our late battle fields. It impresses us as somewhat strange that such long intervals of time should separate the more important advances in both medicine and surgery. There was very early a subdivision of practice into many specialties, and the specialist, jealous of any special knowledge he might possess, kept secret the more dexterous special operations.

The change has been a radical and welcome one. Now through our society discussions, our journals filled with communications containing all the marks of finish and elaboration give us about all that is well done in our profession. The best evidence is that it has been scarce a decade since many troubles to which women are subject, and for which now operative procedure offers relief and cure were regarded by eminent men of the profession as mythical. The enlightenment of the general practitioner, the increase in his diagnostic ability and the improved skill and methods of the specialist have rendered our phenomenal advances possible. No longer overborne by empiricism we allow the fixing of no limit to our improvement and discoveries. New views and methods will be continuously evolved to take the place of those which have proven fallacious. A courageous, almost audacious spirit of inquiry is doing the work. No one man or clique of men can come to us with their little discovery or their "my method" and say to us, "It is science—it is truth—it is faultless." We want to make some inquiry for ourselves. They must have the support of a resistless logic before we will grant their claim—they must bear the signet of truth as established by an unbroken line of successful use. There will continue to arise many moot-questions, both in specialism and in general practice,—to the adjustment of these there will be brought to bear the collective experience and the attested results of scientific research. There are some advantages the specialist has over the general practitioner. The general practitioner cannot to the same extent as the specialist control environment and sanitary conditions.

Neither the specialist, the general surgeon nor the general practitioner need attempt to arrogate to themselves all the honors. The honors are of easy distribution—they go to those who do successfully the work which lies within the legitimate limits of their departments. That general practitioner possesses the finest touches of the skilled specialist who early discovers and promptly deals with troubles needing operative interference, who through close study and observation has a clinical knowledge of suppurative forms of pelvic and other diseases. There is the best of literature on all subjects coming within the scope of his field.

The educated, conscientious and zealous workers of the profession will most heartily endorse the statement of Dr. Thomas M. Dolan that, "Those who are engaged in general practice have no reason to complain of the growth of gynæcological specialism which has followed on the line of progress and of evolution, for the general practitioner and specialist have still their *rôles* and are mutually interested in the development of the study of the diseases of women; nay more, I would assert that by linking themselves with such societies as our Gynecological, and by digesting the experiences which the leaders in gynecological practice so readily place at their disposal, general practitioners can thereby better qualify themselves for that position which, if I read rightly the signs of the times, they are likely to hold in the

future. It appears almost a certainty, that the differentiation in the ranks of the profession will be of such a nature that we will have two orders: first, a family physician or medical attendant, who will have the general care of the public; and secondly, that we shall have behind them an order who devote themselves exclusively to the study of a single part or parts of the body. It is a growing opinion that the specialist should for some years be a general practitioner, and that then by predilection for some individual organ or part of the body, he should take up that as his specialty. The field of medicine, and especially gynecological medicine, is so vast that it is only permitted to general practitioners to have sufficient knowledge to treat the ordinary diseases of womankind; and at the same time he should be able to accurately diagnose those conditions for the relief of which he should seek the aid of those who have taken up the speciality. What is wanted by the general practitioner is guidance and instruction in the diagnosis of obscure conditions. He is willing to learn, to keep pace with the times; and it is important that he should familiarize himself with the symptoms of myoma, multi-nodular fibroma, ectopic pregnancy, salpingitis, suppurating forms of tubal disease and the numerous accidents incident to parturition—he should possess a knowledge of the retrograde changes incident to the growth of hard tumors and the retrograde changes and accidents incident to cystoform growths. It must be remembered that in many cases time is of the greatest moment, and an early diagnosis means a difference between life and death. Early operation is or should be, a gynecological maxim."

There should be no antagonism between the specialist and the general practitioner, the one ought to be able to cope with the ordinary run of practice,—because specialists themselves have been so liberal in instructing, through our society meetings, elaborate, scholarly papers, textbooks and free clinics,—opening our eyes, and making their knowledge the common heritage of medicine. But our work must stop and have its limits, we must in cases of doubt, in cases abstruse, in cases recognizing special operative measures, invite the aid of the specialists, aid which is always readily given, and aid which we should all the more readily invoke because they are not our competitors, as they have given us the wider field. The field of general practice, so far as the diseases of women are concerned, leaves to the general practitioner an enormous scope of work almost sufficient to satisfy any ordinary ambition, and if he is sufficiently qualified to faithfully, judiciously and scientifically carry out the treatment of the general ailments of women with minor surgery, he may congratulate himself that in some measure he is contributing to the advance of gynecology—and to the happiness of that sex to which our study is devoted. If in general practice we are consulted about a case, and we cannot diagnose it accurately, it is criminal to carry the patient on for weeks or months without seeking other advice. The grave fact that it is human life we are dealing with should drive away every selfish consideration, every prejudice, personal and impersonal, and urge the use of our best wisdom, all the lessons of our study and experience and the summoning to our aid that of others. From the stand-point from which we have considered our subject we cannot escape the conclusion that specialists should be for some years general practitioners. That though each works in his own sphere they are working to a common end, the building up of the science, the perfecting of the art of relieving suffering and preserving human life. That there exists no grounds for narrow prejudices nor antagonisms, one is the servant of the other,—both of humanity. That our

correction of errors, our advance in the exactness of knowledge, is largely dependent upon the most hearty of co-operative effort; and that the general practitioner should be prompt to call to his aid the specialist in all cases which medicine cannot benefit and for which good surgery is the only remedy.

TREATMENT OF RABIES BY AN INTRAVENOUS MODIFICATION OF PASTEUR'S METHOD.

Under this heading was recorded, in the *British Medical Journal* of April 30th, an account of Professor Murri, of Bologna, which, while being treated with Pasteur's method, developed all the symptoms of paralytic rabies. These all cleared up when intravenous instead of subcutaneous injections were made. Dr. Bordoni-Uffreduzzi takes exception to the interpretation put by the original reporters on the above case, and suggests that the rapid recovery after the intravenous injections might very possibly have occurred without any treatment. To emphasize his remarks he reports a case which came under his own observation in which a patient, bitten by a rabid dog and treated by the Pasteur method, suddenly towards the end of the treatment developed symptoms of advancing paralytic rabies. In this case the patient recovered perfectly though the only treatment adopted was the use of a mild laxative and a good diet. Dr. Bordoni-Uffreduzzi also refers to two "exactly similar cases" recorded by him some time ago, in which like simple measures were effective. These remarks have led to a rather sharp rejoinder by Dr. Novi, one of the writers attacked, in which he claims that the "two exactly similar cases" were by no means proved to be suffering from true rabies at all, as they presented only the subjective symptoms so common in people who may have been bitten by suspected but not rabid dogs. He also points out that the entire records of the Institut Pasteur contain no instance like that just narrated by Dr. Bordoni-Uffreduzzi. Thirdly, he maintains the complete justice of his deductions in favor of the intravenous treatment, also challenging his opponent for not having included the above-mentioned case in his statistics published in June, 1891.—*Brit. Med. Jour.*

Clinical Lectures.

BUFFALO GENERAL HOSPITAL.—SURGICAL CLINIC.

PROF. ROSWELL PARK, A. M., M. D.

TREPHINING FOR EPILEPSY—TRAUMATIC ASCENDING NEURITIS AND POSSIBLE EMBOLISM OF BRACHIAL ARTERY.

The first patient this morning is an Italian boy, aged seven, whose history has not been written. The parents are ignorant and the child says little that can be understood. When quite a little child, he was struck on the forehead by a stone while fighting and suffered a depressed fracture. He now shows a scar on the forehead, there is an irregularity in the contour of the bone with evident depression and the child has well-marked epileptic fits occurring once in three or four weeks. I consider the case very favorable for operation now, whereas, if operation were delayed till the fits come on frequently, the prognosis would not be so good. The lesion is evidently of the frontal lobe of the brain and, as we believe the frontal lobes to be the seat of the reasoning processes and perhaps also of that unknown affair which we call imagination, we would not expect to notice motor phenomena while we would be apt to note loss of memory. We have not had an opportunity to test the memory but, for practical purposes as an indication for operation, it is enough to know that the child has epileptic seizures and has this depressed fracture. In any young person a depressed bone pressing upon the dura-mater, or on the brain itself, is a source of especial danger, not always attended with bad results, but like a weak bridge which one may cross without falling through is always likely to cause a disaster.

On the boy's forehead you will observe a scar which I shall outline so far as possible in making my incision. It is always good practice even when the cosmetic effect is not essential to make a wound which is

as little disfiguring as may be, hence, if the patient has a scar in which the fresh incision can be made, it is better to follow it. There is, in such cases as this, another reason why it is better to make the incision in the line of the previously existing cranial scar, for epilepsy may be due merely to the irritation of the cicatrix.

Forty-eight hours previously to entering the clinic room, the boy's head has been shaved and covered with a sublimate dressing. This is now removed and the forehead shaved in order to remove the down and particles of epithelium and other debris, for the razor is a dermal curette as well as an instrument for removing hair. The field of operation is scrubbed with soap and water and then with a potassium permanganate solution, followed by a solution of oxalic acid to remove the discoloration. The periosteum is exposed by curved incision through the overlying tissues and opened by a crucial incision. The deeper portions of the wound I find quite dark, probably stained by particles of dirt or coal-dust incorporated in the flesh at the time of the original injury. I have already told you in the didactic lectures that in young children, there is but one table of the skull unless the frontal sinus happens to be unusually well developed, when the bone in the supraorbital regions is divided into two portions. In this case there is more than the ordinary amount of venous oozing from the trephine wound. There is only one safe rule to follow in the use of the trephine and that is to set aside all generalizations as to the thickness of the skull in persons of different ages and to proceed as if you knew the bone were very thin. To my surprise, I find quite a well marked division of the bone into tables. I will pass around the button of bone which I have removed so that you may see the irregularity of its inner surface. As I do not wish to leave any sharp points of bone to excite fresh irritation, I trim off the margins of the trephine-opening with forceps and then with the bone chisel. The inner margin of the opening is over the longitudinal sinus. I am searching with the probe for abnormal adhesions between the dura and the bone and I must not mistake the natural connection between the dura and skull at this point for an inflammatory process. There seems to be no indication for further interference within the skull. As it is quite likely that some of the foreign material and the cicatrical tissue in the old scalp wound have been irritating, I dissect it all out. The periosteum is closed with fine cat-gut and the external wound with buried cat-gut sutures which have the advantage of leaving no cross marks to show in the scar.

A week ago a lad eighteen years old fell down four stories in a dummy elevator. One shoulder was badly bruised and there was soreness in the pectoral region. He suffered a concussion of the brain but was able to move his arm in almost all directions. We found that sensation was preserved all along the arm, that there was freedom of motion at the shoulder, that the hand could be placed on the other shoulder with the elbow touching the chest, and, in short, by the customary methods of examination, we ascertained that there was no fracture nor dislocation. The boy, however, had been badly bruised and shaken up and was quite ill and, more recently, other symptoms have developed which make his case really serious. The left arm is now almost completely paralyzed. This was not the case on the first or second days after the injury but has been of more recent development. I scratch the skin of the fore-arm quite vigorously with a pin, the patient gives no sign of sensation but sensation begins as I get up toward the shoulder. This test must be made not only along one aspect of the limb but on all sides for as we have three principal nerve-trunks supplying the hand and fore-arm, namely, the median,

the ulnar, and the radial which is a continuation of the musculo-spiral nerve. The wide-spread insensibility which you have seen demonstrated indicates that all branches of the plexus going down to this part are involved, whatever may be the explanation of this injury. There is absolute paralysis of the fingers, hand and wrist. The patient can move his shoulder slightly and he can turn over although he could not do so yesterday.

What is the condition here? There is no question but that at the time of the fall, the patient sustained a severe contusion of the shoulder and especially of the deltoid muscle which acted as a sort of cushion. There was a fear that he might have had a fracture of one or two ribs on this side but I have not been able to get any crepitus nor other sign of such an injury. When he takes a long breath, he has no more pain than would follow from a contusion of the soft parts. Sensation and motor power were excellent for the first forty-eight hours and were then gradually lost. This means, of course, trouble with the nerves. Is the lesion in the brain, in the spinal cord, in the roots of the nerves or in the brachial plexus? We can exclude brain injury for in all probability its worst manifestations would have been the earliest, there is no hemiplegia nor papillary disturbances nor any symptoms of interference with speech, any of the special senses or thought. Hæmorrhage into the spinal cord may cause the development of a gradual paralysis but in this case the paralysis is not extensive enough to be explained in that way. We can scarcely imagine an amount of compression which should affect the arm with so marked paralysis and not involve parts supplied by nerves coming off from the cord lower down, at least on the same side. By the localization of the paralysis in the arm, we are brought to the diagnosis of trouble in the nerves after they have left the spinal cord, the case is one, therefore, of peripheral lesion. I have already shown you, this term, cases of injury to the deltoid muscle with involvement of the circumflex nerve and subsequent inflammation or degeneration, producing paralysis, and have told you that this paralysis may be permanent. Sometimes, also a similar paralysis is caused by the pressure of the head of the humerus on the nerves during dislocation. But there was no dislocation when the patient entered the hospital and if he had a dislocation at the moment of injury it was immediately reduced without being recognized. We must account for the trouble on the theory of a peripheral neuritis of an ascending form. The circumflex nerve was probably the first one to become involved and the inflammation has probably spread to the other branches of the brachial plexus.

There is another important feature of of the case. As I press my finger over the point where his left radial pulse should be felt, I get a very slight pulsation. Now it is possible by pressing the finger against any hard surface to feel a pulse-beat in the finger itself. The determination as to whether I feel my own or the patient's pulse-beat must be made by feeling his other radial artery and noting whether the beat is synchronous or not. I find to-day, what I did not find yesterday, that the pulsation in the left radial in his own. Yesterday I could not detect any radial pulse in his left wrist. Inflammation of the brachial plexus alone could hardly account for this circulatory phenomenon, there must be some interference in the course of the artery. It is impossible to imagine an injury such as this patient has undergone without a certain amount of damage done to the blood-vessels in the axilla. For example, there may have been a thrombus in the axillary vein pressing on the artery or there may have been an injury to the arterial wall or an embolism of the artery. If there is an embolus occluding the vessel, it could scarcely have come

from the heart for the patient had previously been healthy. But there may have been some injury to the artery in the beginning, a thrombosis, and in the course of forty-eight hours a little particle may have become dislodged and carried down into the radial artery so as to shut off its pulsation. If this were to occur in a person where sensations were normal, he would become conscious of a sharp pain in the arm but on account of the anæsthesia in this case, there may have been an embolism of the radial ariery without the patient noticing any change. Again, there may have been a hæmatoma pressing upon both the vessels and the nerves but within the week which has elapsed since the injury, we would expect a perceptible swelling in the axilla and a discoloration of the skin to appear, neither of which signs are present here. The pulse might be shut off by pressure inside the thorax but auscultation and percussion reveal no interference such as effusion into the pleural cavity or consolidation of lung and there is no reason to believe that there is such an internal lesion. The interference with the function of the brachial plexus must of course, be due to trouble outside the thorax, that affecting the blood-vessels might be either inside or outside. The case is somewhat obscure but I believe we have to deal with an ascending neuritis and a partial occlusion of the axillary, brachial or radial artery either by pressure in the axilla or by an embolus lodged farther down.

I am applying blisters over the course of the brachial plexus with the idea of producing counter-irritation for the somewhat hypothetical condition of neuritis. After a time, if recovery does not occur, we must use both galvanic and faradic electricity, the former to maintain the nutrition of the nerves, the latter to keep the muscles in a proper condition and to prevent their atrophy from lack of use. Although the case is a surgical one, I see no indication for operating at present.

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, August 16, 1892.

J. M. Batten, M. D., President *pro tem*, in the Chair:

Dr. J. J. Buchanan reported a case of bone grafting as follows:

I wish to show a case to-night which illustrates the subject of bone grafting in two of its aspects. This boy 11 years old, came to this country a year ago last December. Previous to that time he had been perfectly healthy. Before he came on ship board he is said to have struck his foot or the lower part of his leg and received a very trifling injury. After arriving on the ship he was taken with a high fever and great pain in the leg from the ankle to the knee. Expectant treatment was adopted, and when he arrived in Pittsburgh I was called to see him and found the limb swollen and filled with bloody pus. I made an incision the first evening and liberated an immense discharge of bloody matter, and found the bone affected. I had him removed to Mercy Hospital, where I etherized him and made a long incision down over the inner surface of the tibia and found the bone had been the subject evidently of acute osteomyelitis. The entire lower three-fourths of the shaft of the bone was destroyed. I extended my incision from a little below the junction of the upper with the second fourth of the bone down to the ankle joint and removed the lower three fourths of the shaft. The loss of bone was complete. I do not think there was a particle of periosteum left. The shaft of the bone was preserved, and I think it is intended to be an heirloom of the family, but I neglected to have it brought here this evening. The limb was so useless, having lost threefourths of the tibia and the corresponding part of the ankle joint, that that I proposed amputation to the family but they rejected it, and I was very glad to be able to try to graft some bone to take the place of this that had been lost. I disinfected the cavity as thoroughly as I could and packed it with iodoform gauze.

The constitutional trouble disappeared at once. I put the limb in plaster paris and in a few days removed the packing and found healthy granulations springing up throughout the cavity. I then repacked it, and on the sixth or seventh day secured two puppy dogs, chloroformed them to death and removed the long bones. From the neighborhood of the epiphyses, with rongeur forceps I took out pieces about the size of a grain of wheat and planted about fifty of them, along this gutter, just as a person would sod a ditch placing the periosteum next the granulations. I then put on the dressing, with impervious tissue next the grafts, and did not disturb it for four or five days. When the dressing was removed it was found that nearly all the grafts had taken. They could not be pulled off with forceps without considerable force. The granulations soon covered them up and I applied a lot about a week later, and the boy went on to recovery and has a very useful leg. This was more than a year ago. I should say that before the boy was out of bed, he commenced to have abscesses on different parts of the body. The first one I believe was over the lower end of the fibula on the other leg and the next over the lower end of the ulna. He then got abscesses in the soft parts of his legs and arms. These abscesses continued for about a year but did not confine him to the house. About three weeks ago I was sent for to see him. He had severe pain in the region of the head of his tibia on the same side as the original trouble, and from the considerable amount of fever, the absence of any cause for the symptoms, and also the existence of tenderness over the head of the tibia, I concluded he had a bone abscess. I had him removed to the hospital, where I cut down on the head of the tibia and chiseled open the bone, and found the entire head of the tibia filled with pus.

I scraped this cavity out as thoroughly as possible. I made a liberal opening in the bone, and the entire inside of the head of the tibia was removed. After disinfecting it I packed it with decalcified bone chips by Senn's method, putting in iodoform powder. The result was that there was no discharge from the head of this tibia whatever. The operation was done about eighteen days ago, and by the old method of treating these cases, we would have had suppuration for a considerable period, but this boy since that time has never had a particle of trouble and no discharge, except lately a certain amount from the superficial granulations. At the time, just as the abscess was opened, I had a culture made of the pus and I will show it here; it proved to be *staphyloccocus pyogenes aureus*. It is a question what caused this abscess in the head of the tibia; whether this was of the same nature as the subcutaneous abscesses that he had at various times during the last year, or whether these germs had laid dormant in the head of that bone from the time of the first operation. Now, whether this abscess was due to those organisms which had set up the original trouble or whether it was mere accident that he should get this new trouble in the head of that tibia near the old trouble, I am unable to determine. I rather think that the germs were there during the whole year. This case represents the two methods of bone-grafting, one by the application of living bone direct from an animal and the other by the use of decalcified bone. I expected to have another case to-night, but unfortunately the boy went out of the hospital this morning without my knowledge. In that case also the decalcified bone made a perfect result. The boy was only dressed two or three times during his stay in the hospital and the case was without any trouble whatever. Now with regard to the choice of these two methods of bone grafting, I should say that if we have a cavity in the bone, that we ought to take the decalcified bone to fill it. If we have a gap in the bone from which we must take a new start, then we should take the bone with its periosteum in small fragments, from an animal, preferably from a young one. Now the reason these bones are cut up in very fine pieces will of course suggest itself, that in case any of these failed to unite, it could be removed without any trouble. Fortunately in this case they almost all took hold, although there were seventy-five of them; but I believe if we had put in large pieces, portions of some of them would have failed to unite, and the removal of these portions would probably have destroyed the usefulness of what was left behind. For that reason I would always prefer putting in small pieces. I expected to show another case illustrating the grafting of living bone.

where three and one-half inches of the lower end of the tibia was removed and one and one-half inch of the fibula. I grafted this case with the bones of a young puppy. In it I put fifty to seventy grafts and that case also I considered a case of amputation; but after the man's refusal to be amputated, I agreed to try and repair his bone and the result was very good. When I last saw him, a short time ago in the Hospital, he was able to walk on his limb, but the bone was not entirely firm. For a week or ten days after the injury the head of the astragalus was to be seen in the wound.

Dr. Thomas: Many of these cases of diseased bone are troubled with wonderfully,and even where there is not a great deal of lost bone. I sometimes think we graft without periosteum. I cannot account for it, but we get new bone where we think the periosteum has all been destroyed. About one and one-half years ago, a case of complicated fracture of the ankle-joint came to the South Side Hospital. The lower section of the tibia had been broken off diagonally about two and and-half inches above the joint. The tibia had been broken off and the lower end of the fibula. A short piece of the lower fragment was imbedded in the fibula, and it was impossible to dislodge it from that position without incising all around it, and taking it out with the forceps. In that case I wanted to amputate the limb, but the patient demurred. No pus appeared in the wound. This bone was regenerated, and the man to-day drives a beer-wagon. In that case I thought, and think still, that the bone was regenerated without periosteum. Now in this case, if the entire tibia was removed, as the doctor says, we have a regeneration of bone, we have the outlines of the tibia, and we have in a manner cured, but we have not got a complete cure in this case as yet. It is a question with me if it were not better if that limb had been amputated, than as it is. The probabilities are it will never get well, and the probabilities are amputation will have to be done yet. I do think we sometimes carry our conservative surgery too far. I hope I am mistaken in this case; but my opinion is, it would have been better if that limb had been amputated. The patient would have been saved many hours of being bed-ridden and many hours of pain, and, at present, would have been able to walk a great deal better than he does.

Dr. Duff: From what I have seen, I have not practiced bone-grafting myself, but I have seen and read, and I think there is a very bright future before us in bone-grafting, and yet we want to bear in mind, as Dr. Thomas says, that bone has very great recuperative power. I had a young lady come to my office this morning who is not over 21 years of age. I have only seen her occasionally in the past few years. In the fall of 1876 she took scarlet fever. She suffered a relapse, and one abscess after another formed. I removed eighteen pieces of bone from her humerus and from the spinal processes. I cannot state the exact number, two or three were removed from the femur. This condition ran on for a long time, when it became evident the tibia would have to be removed, and in the presence of Drs. Sterling, O'Connor and my father, I removed the shaft of the tibia, removing all of the bone, which I still have in my possession at my office; all of the shaft of the bone, and, I thought at the time, all of the periosteum. I advised amputation at that time, but we thought we would await results. Within six months after that there was apparently a complete bony formation in the midst of the tibia. It was very much thicker than the tibia originally, but it was solid. She is a twin, and the two sisters resemble each other very much. She walks by the side of her twin sister to-day, and it is with difficulty you can tell which is the lame one. I have asked this lady two or three times to come before the society, but she is very modest, and I cannot prevail upon her. I shall be glad at some future time to show the bone which came from her. This case, with some others not so aggravated, leads me to believe the bone has greater recuperative power than we generaly attribute.

Dr. Buchanan: Of course, if the periosteum of the case I have just shown remained, we need not lay any stress on the grafting of bone; but, as I stated, to the best of my knowledge, nothing of the periosteum was left. Now, of course, this is a matter which I cannot prove, even to myself; but to show that bone-grafts can grow without the aid of the original periosteum, I would refer to a case of Dr. Macewen, of Glasgow. The

shaft of the humerous was almost entirely gone, and it had been gone for more than a year. The arm was a perfect flail, but, by repeated graftings of bone, the humerus was replaced; the pieces were set into the gap made between the muscles by dissection; the only guide was the anatomical one of the positions of the muscles. Here several inches of the humerus was gained by bone-grafting, and in this case it is not necessary or not possible to give the original periosteum any credit for the result. Now, with regard to the comparison of this leg with an artificial one, I had hardly expected this criticism, I must say. I think this leg is a good deal better than any artificial limb I have ever seen.

Dr. E. G. Matson opened the discussion of the subject announced for the evening, entitled:

NEPHRITIS.

(*Abstract of the Paper.*)

The writer pointed out that each uriniferous tubule was a kidney complete in itself. In this fact may be found the explanation of the insidious character of some forms of disease of the organ when the morbid process fastens at first upon a part of the tubules leaving the others to continue the urinary function. The lesions are always found to have their primary seat in the cortex, that is to say, in the part of the kidney which performs the vital functions of excretion. It is a fair presumption, therefore, that the origin of nephritis is connected with the excretion itself. This evidently is true in nephritis from lead or phosphorus poisoning. It is possible that in every case the disease arises from the necessity of separating some substance from the blood for which the organ is unsuited, and which is injurious to its structure. This is easy to believe in cases which are intercurrent or sequelæ in infectious diseases. It is not conceivable that exposure to cold could directly affect the kidney more than other organs. It is probable that its well-known agency in this disease is connected with the production of substances which the kidney must deal with in greater quantities than it can bear. If the substances in the blood, with which the kidneys are concerned, were totally incompatible with health, it would be necessary to place the organ next the heart so that they could depurate all the arterial blood before it is distributed to the tissues. Their position on a branch, not large in comparison with the main current, shows that incomplete depuration of the blood is sufficient. It is not easy to understand the causal connection of hypertrophy of the heart with Bright's disease. Evidently it develops in response to a condition of the blood in which the substances to be removed by the kidneys tend constantly to exceed the proportions compatible with health. The hypertrophy of the heart is compensatory to the destruction of a part of the kidney just as much as in valvular disease. By this means the blood is driven at a higher pressure though the lessening intact part of the kidney, which in this way can act on great a part of the blood as in health. The morbid anatomy was discussed: it was pointed out that both interstitial and parenchymatous changes were found in all cases so that the classification into interstitial and parenchymatous nephritis, though convenient, is not strictly correct. Probably (after excluding waxy disease) the best division is into acute or chronic parenchymatous and interstitial nephritis. The division is justified by difference in morbid anatomy as well as clinical history. They are probably only varieties of one disease, and therefore there may be some cases of uncertain classification. The course, symptoms and diagnosis of these forms were detailed. Interstitial nephritis, the most insidious, presents the greatest difficulty. Albuminuria is but transient, dropsy usually absent, while the eye-ground is inaccessible to the majority of physicians. If there is hypertrophy of the heart without defect in its mechanism, arteriofibrosis so that the radial can be felt like a cord against the bone below the point where it is compressed by the finger; accentuation of the second sound of the heart over the aortic area, with *persistent* low specific gravity of the urine, that is with a *persistent* deficiency in the quantity of solids which it is the duty of the kidneys to excrete, diagnosis of interstitial nephritis is justified.

Since Bright's disease is often insidious the disturbances must be borne in mind which it may cause. Tendency to bronchitis, dyspnœa, neither due to heart disease, emphysema or asthma, repeated attacks of diarrhœa, or vomiting on slight provocation, are among those which should lead the practitioner to entertain the pos-

sibility of Bright's disease. As to uræmia, which is sometimes the first sign of the disease, it should be remembered that it may appear as headache, mental wandering, delusion, or even mania. Albuminuria is always a symptom of great importance. Probably all physicians are aware that albuminuria is not a pathognomonic sign of Bright's disease, but there are not a few who suppose tube-casts to be an inevitable sign. Practically, tube-casts and albuminuria go together; the same causes seem to produce both. From what has been said of interstitial nephritis, it is evident what caution must be observed in pronouncing a subject free from renal trouble after an examination of his urine. On the other hand if a faint cloud of albumen is found, what are we to say? Albuminuria is in the great majority of cases due to Bright's disease. To prove that is that not an outside cause should be found. Doubtless, albuminuria never exists without disorder of the kidneys. This disorder is generally secondary as cyanosis due to heart disease, or biliary intoxication. The disorder is probably functional and unimportant at times. Functional albuminuria is said to be not uncommon at about the age of puberty. The odds are heavy against the health of a grown man free from jaundice who has albuminuria.

Dr. Grube: I was pleased with the doctor's remarks, and, as I have given this subject a good deal of attention, have had a great deal of experience in making analyses. I am glad he has brought out several points and none more so than that both albumen and casts may be found in the urine, with at least no serious trouble in the kidneys. I have found both, and afterwards had the privilege of examining the kidneys. post-mortem, and could find no trouble there. Because we find a few casts, because we find a little albumen, we often come to the conclusion that the patient is suffering from Bright's disease, when that probably is the smallest factor in his trouble. Now on this point I want to tell my own method of searching for casts. I take low power, not more than one-half inch, a which gives a wide field. I put five or ten drops of urine on the slide without using a cover glass, and in that way if there is a single cast in ten drops it is possible to find it, A thing which must not be overlooked is that casts are so transparent that if you have not very low light they become entirely transparent, and you cannot see them at all. As long as the specific gravity is high enough and the amount in twenty-four hours is sufficient to show that the renal function is being performed the patient may live in comfort, if hygiene is attended to, and therefore we have less field for treatment and management, mainly a question of diet. Prof. Dixon is a great admirer of the skim-milk treatment; not that any thing it contains has a good effect, but it gives rest to the kidneys. You want to give a diseased kidney rest, and to do that minimize the diet by giving skim milk.

Dr. Shaw: I agree with the last speaker in referance tofinding casts with a low light. with a very strong light you cannot see them at all. but with almost no light they come in view very readily, when otherwise they might be overlooked.

Dr. Shaw then referred to two cases met in life insurance examinations, in which slight digestive disturbances alone indicated ill health. The urine, however, showed a faint cloud of albumen and contained tube casts. Both these men were considered healthy by their physicians, yet both were dead in the course of a few months.

Dr. Batten: This was a very interesting subject the doctor read upon this evening, and I am sorry he did not go into it a little farther. Now there are a great many cases that come under my observation that require very skillful treatment. I remember the first case that came under my observation several years ago when treatment was not so well understood as it is now, and I remember that I gave a very unfavorable prognosis, and I treated the case with compound jalap-powder and so on, and to my astonishment the patient got well. I had another interesting case of that sort that came under my observation in a man who who had an acute nephritis from sitting on the ground. It was in April. My treatment was hot baths and the compound powder over the bowels. The question of prognosis in these cases of chronic albuminuria I think is very important. For instance, a man may have only one kidney attacked with chronic-nephritis; if we only thought there was one kidney affected we could give a very favorable prognosis. Again, only a part of the kidney may be affected; in such a case the

prognosis would be favorable. In regard to the treatment of nephritis, we have an increased blood supply to the kidneys. We should prevent this increase of blood and endeavor by some means to dilate the vessels so that the blood can escape. Now to do this, it would be necessary to prescribe some drug that would prevent the heart's increased action, and in addition to that give a remedy that would dilate the vessels so that the blood could escape from the kidneys. For the first we have digitalis, and for the second we have extract of belladonna. With these drugs prescribed in a scientific manner and with the proper diet, I think the patient would be very greatly benefited.

Dr. E. G. Matson: The last speaker thought a single kidney may be affected by Bright's disease. I have never seen the description of such a case. It is true that in autopsies one kidney is often found more extensively altered than its fellow.

Dr. Batten: I have a case that I would like to bring before the society. A woman gave birth to her fourth child on Jan. 15th. On the 16th of the next month, after washing all day, she was taken with puerperal peritonitis. The question arises in my mind how did this contagion enter the system one month after the child was born? Dr. Batten also described a case of mammary abscess without abrasion of nipple.

Dr. Duff: As we see the subject to-day, I think that we ought to speak of these troubles under the heading of puerperal infection. If there was peritonitis in this case, which was puerperal, and it was the result of infection, it would come under the head of what is generally known as puerperal fever, unless we could determine that it was in her system for some time before. Prof. Hurst and others say with regard to the abscesses formed in the mamma that they can not occur unless there is an abraded surface on the nipple, but on the other hand it is asserted there can be abscess of the breast where there has been no abrasion or cracking of the nipple, and it is caused by the staphylococcus which has been introduced through the blood. In Dr. Batten's case germs may have been introduced through the blood. I believe I heard Dr. Murdoch several years ago, when the germ theory first came out, say there could not be a drop of pus in the body unless we had one of those little animals introduced there first. If it is not possible to have a drop of pus it is just as impossible to have puerperal peritonitis or infection without introduction from without or through the blood.

Dr. Buchanan: I understood Dr. Batten to say that thirty days of the puerperium had elapsed before trouble commenced. I think this woman had a trouble which was not puerperal. She had passed her puerperal period. If this woman had had any elevation of temperature, any infection of the tube with a production of pus in that tube, and at the end of thirty days had had a leaking or rupture, causing peritonitis, then it might be called puerperal fever, but if she had passed, as I understood, thirty normal days after labor, I think we would have to bring some other cause in to account for this peritonitis.

Report of Two Cases of Stone in the Genito-Urinary Passages, by Dr. Thomas.

The first case was a case of long standing. The patient complained of urinary trouble for three or four years. It was suspected that he had a calculus in his bladder. Yet his bladder had been examined by some very capable gentlemen several times, and they never were able to detect a calculus in his bladder. I examined him myself three or four times, but I could never detect anything in the bladder. In addition to trouble in the bladder he also complained of his right side, and finally the trouble in his right side appeared to annoy him more than anything else. Not being able to discover anything in the bladder I suspected that it existed in the right kidney. At the urgent solicitation of the patient I cut down upon the right kidney about the end of June. and manipulated it thoroughly, but failed to discover any evidence of stone in the kidney. The wound healed finely without any pus in three or four weeks. The patient complained afterwards of trouble in his urinary apparatus. Dr. Martin sounded him with a searcher and discovered a stone in the bladder, and result was what I show you here. (The extracted stone was here shown.) Now the question is whether the manipulation dislodged it from the pelvis of the kidney, or whether the

calculus had not been in the bladder all this time. Dr. Banks, of New York, discovered a calculus in the bladder three or four times, though the patient had been examined by very able men in New York City, who had failed to discover it, and he claims if you cannot discover one the better plan is to put the patient in bed, and very often you can discover a stone where you could not without this preparatory treatment. The peculiarity of this case, as well as the case following it, is that the patient should go around so long without the discovery of so large a stone. This stone weighs nineteen drachms plus.

The second case was sent to the South Side Hospital. He had been suffering for three years with urinary troubles, and in the mean time he had acquired a gonorrhœa. This patient was treated by six or seven physicians in this city. He had had no control of the sphincter for a long time; about every half minute he would eject what urine was in the bladder. I suspected from the statement that he made that I would find a very tight stricture. I first passed in the searcher and found a stone. I think it was removed July 7th. This is an oxalic acid calculus. The patient had been suffering for fifteen years, and it was never discovered untill he came to the city. I had my reason for performing lithotomy instead of litholapaxy; the bladder was inflamed and contracted, and I thought by this operation perfect drainage would be secured, and the bladder get a long rest, and in that way recover. The first patient left the hospital in twenty-one days, while the second one expects to leave to-morrow. Both have made a wonderful recovery. The second patient's temperature went up to 106 on the second day, then it gradually went down, and in four days was about normal, and remained so since. These cases went on for a long time; if they had been discovered earlier the calculi might have been removed without much trouble. This smaller oue weighs six drachms plus. I think the first patient had been examined by Drs. Wood and Martin. I could use the cystoscope and pass it all around his bladder, yet I failed to discover anything in the bladder with that, or by the use of a searcher, and it was strange to me if it was in the bladder that it could not be found.

Abstracts.

DISCUSSION ON CHOLERA.

THE ETIOLOGY OF CHOLERA.*

Dr. Chas. Seth Evans:

The cholera germ has been found in all cases of cholera which have been examined for it, but this germ, which, by the way, is a bacillus, has never been found to occur in any other disease. Now, the act of finding these bacilli in cholera may be a very easy or a very difficult thing to do, indeed. If the patient is still alive we look to the stools, but to find them in the stools is not as easy as some might imagine. Especially is this the case in the latter stages when the patient is getting well. In the second stage it is comparatively easy, but in the first and third stages it is not. To examine for the germ, part of the stool is placed on the cover-glass, especially one of the white particles which float in the stool, but not infrequently even then the germ is not discovered. At other times we find in the rice-water stool a great number of the germs.

The method of Schottelius is rather an aid in the detection of the germ. This method recognizes the rapid development of the cholera germ in bouillon and the way it is wont, in its multiplication, to kill off any saprophytes which may be present. Thus, in a day or a few hours we will have almost a pure culture of the cholera germ. By this methed one is able in every case of cholera to detect the germ. Of course, in this method of Schottelius it is necessary to take out one of these white floating bodies. Then, of course, the germ may be put on the cover-glass and there stained. Now, what are the properties by which this germ may be separated? In the first place, it is a bacillus with square ends, about one and one-half micro-millimetres in length, and one-sixth of the same in diameter. The bacillus is, moreover, not straight. The younger bacilli are sometimes straight, but they become crooked as they grow older. We find them, the younger ones, straight, and others curved, and still others may be in the form of a half circle. It is this curvature of the bacilli which has given to it its name, the the comma. When these bacilli occur in

*Cincinnati *Lancet Clinic.*

pairs, their curvatures are almost invariably in opposite directions, so that we get more or less of an 'S' shape. Now, in those cases where the bacilla come out in a chain and form a spirillum, we find that this is continued, its curvative being not only in one plane, but in all three planes, and we have a cork-screw arrangement; and this was thought for a time to be typical, but by photographing, and the use of the higher powers, we find that it is made up of bacilli; and we find that this cork-screw form develops especially well when the bacillus is growing under unfavorable circumstances, that is, when it is losing substance and becoming exhausted. The comma bacillus possesses the power of independent motion. In a hanging drop preparation they swarm as insects in the air, like gnats.

As to the formation of spores: Although it is a subject as yet not settled, we may say that there is nothing which represents the permanent form. There have been forms created which were supposed to be spores, but the fact is they are not more resistant than the bacilli themselves.

As to the cultures, that is the means by which we recognize them from other bacilli. They are peculiar. If one pours gelatin plates after the usual manner, then after the usual time one sees the culture full of light white spots, each of which represents a colony grown in the gelatin, and, as it grows, it tends toward the surface, and then, after reaching the surface, fluidifies the gelatin.

It is a very marked peculiarity of the colony that it does not tend to fluidify the gelatin in a large flat surface, but sinks down, until the gelatin soon looks more or less honeycombed in spots. We find, under the microscope, the outline of the colony rough, and it seems to affect the whole upper surface of the colony, thus giving it a granular appearance, and at the same time wavy, and this waviness becomes more and more marked as it grows. It looks indeed, as if the colony were sprinkled over with fine glass or diamond powder. The culture in the gelatin tube is very characteristic. The growth first occurs all along the track made by wire, but especially in the upper parts; so occurring there it tends to form a funnel-shaped arrangement, and gives us a deep, comparatively narrow, funnel, and at the same time the gelatin fluidifies so that the upper portion of this funnel is frequently filled with air, and indeed, not infrequently we get a bubble of air in the upper portion. The older cultures of the germ on the gelatin often show the involution forms.

After about eight weeks a cholera germ will die out in its own culture. Thus, a culture on gelatin will keep hardly eight weeks. A culture on agar-agar will, perhaps, keep three-fourths of a year, under favorable circumstances. The germ also grows on potato, and as I have already said to you, in milk, and in sterilized water. Experiments have shown that it is one of the most tender of germs. A temperature of 122° F. stops all growth, as does also a temperature of 59° F. It grows best between 86° F. and 106° F., about the temperature of the body. A temperature of over 122° F. will kill the germ in every instance, while boiling, 212° F., is a very safe method of destroying it; but a temperature entirely freezing the germ and stopping the growth does not kill it. Besides heat and cold, it is absolutely dependent on moisture for its life. Articles which have become so dry that they are dusty, do not contain germs capable of production. Again, it is a germ which is very easily destroyed by germs of decomposition. When put into fluid from an ordinary privy vault it dies out in twenty-four hours, and in fluid taken from the sewers of Berlin, in the course of a few days. It is, moreover, tolerably dependent upon the amount of oxygen and the chemical reaction of the culture medium. Thus, acids speedily destroy it. The cholera-bacillus will grow and multiply in sterilized water, and also what is even more important, in milk, without changing its appearance or taste: but unsterilized milk is not a good culture, probably due to the presence of the other germs contained in milk. It is reported that Koch discovered a great number of these germs in an Indian tank, in which case the cholera-germs had probably won the fight over the germs of decomposition, and then grew and multiplied.

It remains a fact that these cholera-germs are only to be found in the intestinal tract of the body; not in the organs, not in the muscles, not in the blood, but only in the intestinal tract. Now, the question arises as to how the germs get into the body. As Dr. Freemen will tell you they can get into the body by breathing, and I wish

simply to refer to the fact that only dry things will become dusty, and so it is that only dry germs will get into the body by breathing, and drying these germs will kill them. So this would do away with Pettenkofer's theory that we get it through the lungs into the body, and this leaves the most probable way to be, by what we eat and drink. It is a qnestion of how the germ gets from the intestinal tract of one man into that of another. This may be accomplished either directly or indirectly by the food or clothing, or by washing.

Now, just one word as to immunity. I believe it is conceded that one attack secures immunity, but that this immunity would last from one epidemic to another is highly improbable.

THE PATHOLOGY OF CHOLERA.*

Dr. Leonard Freeman: The germs of cholera are confined to the alimentary canal, and, like those of typhoid, almost entirely to the lower portion of the small intestine, because here the peristalsis is less, as is also the acidity of the bowel. The cholera spirillum is exceedingly sensitive to acids of all kinds, and particularly to hydrochloric acid, the normal acid of the stomach.

The pathological changes found after death are not at all so numerous nor great as one would be led to expect from the severity of the disease, and they are practically confined to the alimentary canal, particularly the lower ileum. The bowel shows the effects of inflammation, especially about the solitary follicles and Feyer's patches, the germs having worked their way into the follicles and tubular glands and even between the basement membrane and epithelium, pushing off the latter. The lumen of the bowel is filled with a watery fluid, which resembles gruel or rice-water, and is clouded by growths of micro-organisms, cast-off epithelium, mucus, and *débris* of various kinds. Sometimes the fiuid contains an almost pure culture of cholera germs.

The spirilli themselves are confined to the intestinal tract. The changes in other parts of the body are similar to those occurring in other diseases, except, from its deprivation of its fluid elements, etc., the blood is very thick and dark.

*Cincinnati *Lancet-Clinic.*

The proofs that the spirillum discovered by Koch is the cause of cholera are these: (1) It is found in every case of cholera; (2) it is found in no other disease. A third element should come in here—we should be able to inoculate the germ into animals and reproduce cholera; but, as animals do not naturally have cholera, and we do not care to experiment on man, this link in the chain of proof is worthless. But if a certain germ is always present in a disease, and is confined to that disease, the inference is very strong, reasoning from its presence alone and from what we know of the causation of other diseases, that it is the cause of the pathological condition in question. The fact being admitted, as it almost universally is, that the germ is always present in cholera, if it is not the cause, then it is simply an accompaniment of the disease. If this be the case, it must develop in numbers from some normal inhabitant of the intestinal tract, or else be produced by the transformation of some such inhabitant into the cholera-spirillum. But the careful examination of hundreds of normal stools has demonstrated the fact that no such bacillus inhabits the intestines, and we know, from long observation, that one form of micro-organisms never changes into another form. In a word, the proof for the cholera-spirillum rests on the same foundation as that for typhoid.

A great many people, who should know better, seem to think that the germs of cholera, as well as those of other diseases, can always be seen at once with the microscope alone. This is often impossible, and it may take considerable search with the plate-method before they are finally discovered.

I was speaking the other day with a prominent pathologist in one of our larger colleges. He did not believe in Koch's spirillum. He had made a great many autopsies in Calcutta, as well as examined a large number of stools, and not in one instance did he succeed in finding the cholera-spirillum. He claimed that Koch waited too long before making his examination, and thus allowing the spirillum to grow after death. He did not state, however, whether these investigations were made by the plate-method or by the miscroscope alone. Cunningham, in a recent article, says he found ten different kinds of comma-bacilli in six-

teen cases of cholera, and that Koch's bacillus was not the most numerous of the lot. He is also an unbeliever in Koch's theories; but these theories rest on too firm a foundation to be overthrown by isolated evidence, without that evidence rests on a very firm foundation indeed.

The germ is seldom found in the vomited matter, and then only when regurgitated from the intestinal canal. The bacilli cannot live long in the stools, and after four days, it is claimed, there is no danger of infection from a cholera-stool under ordinary circumstances. The reason is that other germs,—those of decomposition, for instance—soon kill out the germs of cholera. Experiments in this line are, however, to some extent artificial. Cholera-spirilli have been discovered in the foulest kind of water, teeming with all sorts of bacteria.

The cholera germ grows well only in milk which does not contain other germs. In fresh milk it grows quite rapidly for the first few hours, according to Kitasato, and then, as the milk sours, the growth ceases. Hence fresh milk is more dangerous than sour milk, and the longer you keep it the less dangerous it becomes. This does not argue, however, that milk should not be sterilized—sterilization of milk by heat is still our means of protection against cholera, as well as other diseases; but the milk must be sterile.

One of the most important disinfectants, and one to which sufficient attention is not paid, is sunlight, not only in cholera but in various other diseases. Many of the experiments which have been made with various pathogenic germs suspended in water will have to be gone over again, because the effects of sunlight have not been considered.

As is well known, cholera germs cannot stand dryness, even for a short time. There is very little danger from such dry things as letters, dry clothing, etc. Kitasato has made some experiments lately, however, which seem to show that under certain conditions the cholera spirilli may be dried without destroying their virulence.

The germs of cholera find entrance to the system through the mouth and stomach. It is possible that under certain conditions they may be breathed in; but as dryness kills them at once, and they cannot rise from a moist surface, it is difficult to see how they can exist in the atmosphere.

These cholera germs are so sensitive to the attacks of other germs that it seems remarkable that they can be the cause of such widespread and tenacious epidemics of disease. It is so sensitive that, theoretically, we need not be afraid of decomposing matter of any kind after a few days have elapsed; but, practically, it is better to clean up all the filth, because in filth is found the cause of the disease at first. The spirillum will live for months, or even years, but this is only in a pure culture. And pure cultures must be rare in nature.

Acids have a very decided effect on the germs of cholera. Even a 0.2 per cent. solution of hydrochloric acid will kill them, which is true of few other microorganisms. As weak a solution of carbolic acid as 0.5 per cent. makes a good disinfectant, killing them in a few moments. Carbolic acid is better than corrosive sublimate, because it acts better in the presence of albumen.

Experiments on man have not been very numerous, as one would naturally suppose. A Frenchman once made some pills from a cholera stool and swallowed them; he did not get cholera. But all individuals who swallow cholera germs do not get the disease. Hence the Frenchman proved nothing but his own foolishness. In the catching of cholera a thousand and one factors come in. Some of them we know, and many we do not know. There is the condition of the stomach, the virulence of the particular culture of germs, the age, general condition, climate, temperature, meteorological factors, etc.

A man in Koch's laboratory is supposed to have contracted cholera from a culture of the germs, there being no other cases of cholera anywhere near Berlin at the time. He had all the typical symptoms, and his stools contained numerous comma bacilli. During the course in which I participated in Koch's laboratory a careless student knocked a culture of cholera germs from a table, breaking the containing flask and spilling the cultures over a number of us who were standing about. We spent the rest of the week disinfecting. Klein swallowed some fluid containing Koch's comma bacilli. No evil effects followed; but, again, this proves absolutely nothing.

One reason why animals do not get

cholera may be that peristalsis is so active that the germs pass through the alimentary canal too quickly. Another reason is the acidity of the stomach. If the peristalsis be corrected by injections of opium into the abdominal cavity, and the acidity of the stomach be neutralized by an alkali, the germs of cholera may be successfully inoculated in animals and a disease produced closely resembling that in man.

There have been a number of theories to account for cholera. The most important, perhaps, is Pettenkofer's. He admitted that the disease was due to a germ, but he claimed that the germ must first undergo an incubation in the ground before it could produce the poison which causes cholera—that the germ (x) + the ground (y) = the cholera poison (z). Pettenkofer is right this far, perhaps, in that it requires more than the germ alone to produce cholera; but the discovery of the spirillum by Koch, and its life-history, sufficiently does away with Pettenkofer's ideas.

Cunningham and others believe that cholera morbus is really Asiatic cholera under unfavorable conditions for its perfect expression, but that at times favorable conditions arise, and then an epidemic results.

Certain ptomaines, or tox-albumens, have been found in connection with cholera germs by Brieger, Pfeifer and others. Whether the symptoms of the disease are produced by these, or merely by the local action of the germ in connection with the removal of the watery elements from the blood, is not definitely decided. But, as the symptoms of many other diseases have been shown to be due to these poisonous products circulating throughout the body, one would naturally think that cholera was probably not an exception to the rule.

PERMANGANATE OF POTASSIUM IN PHOSPHORUS POISONING.

M. Bocar (*Bulletin Generale de Therapeutique*, April 25, 1892) recommends the use of potassium permanganate in phosphorus poisoning, in a 1 per cent. solution. In its presence phosphorus is converted into orthophosphoric acid, which is entirely harmless. Dogs poisoned by phosphorus and treated in this way have recovered. The permanganate of potassium exerts no harmful influence on the stomach.

THE CHEMISTRY OF CHOLERA *

Dr. S. P. Kramer:

With the establishment of the etiological relation of the cholera bacillus, there presented itself the question as to how the germ produces the symptoms of the disease. As the pathologists have told us, there is no pathognomonic lesion, and so we can hardly say that the germ causes death by destruction of tissue. And so the inference was left that it produces a chemical substance, which, when absorbed, produces the toxic symptoms that go to make up the symptomatology of the disease. The investigation on this line began with the possible isolation of an alkaloid or ptomaine. The investigation in this direction, however, did not yield very profitable results. It was in 1890 that Brieger and Frankel obtained from bouillon cultures, by filtration through Pasteur filters, a substance which they called tox-albumen, which, injected into animals, produced symptoms almost typical of cholera. Shortly after the injection the animals became very quiet, refused food, and very soon became somnolent; the breathing became superficial and the temperature fell below normal; this was followed by death in from twelve to twenty-four hours. From this filtrate they obtained a percipitate with alcohol that had the same toxic properties, only in less marked degree. They found that, when the filtrate was heated to a temperature of 60° C. for a half hour, it had lost its toxicity. Kitasato confirmed these results in a similar investigation.

Within the past year Pfeifer has taken up the subject, and his experiments show that the poison is not so much a secretion of the germ as it is a substance which goes to make up the body of the bacillus itself. He obtained the same fatal results by subcutaneous injection of the germ, killed by thymol or other antiseptics. The animals died in from ten to twelve hours, showing the same symptoms as those described by Brieger and Frankel.

This tox-albumen, or bacteria-proteid, does not stand any great amount of heat for any time, and is very susceptible to chemical reagents.

One word in regard to the effect of the

* Cincinnati *Lancet Clinic.*

cholera bacillus upon the guinea-pig. If the bouillon culture is injected into a guinea-pig the animal dies in about twenty-four hours, with the symptoms mentioned before. The cholera disease cannot have developed in that time, but the animal is killed by the toxic chemical compound in the culture. This was a starting-point, and from this was adduced the presence of toxic albumens.

Now, it would, perhaps, be well to add what has been done as to immunity. Brieger, Kitasato and Wassermann devised a method of immunizing guinea-pigs in the following lines: They said that the germ so reacts on the cells that they produce a something antagonistic to the toxines produced by the germ—an antitoxine, for instance. They then said: We will grow this germ on a substance made from an organ rich in cells; and they took for this purpose the thymus gland of the calf, growing the germ in a bouillon made from these glands. After remaining in the incubator for three days the culture was filtered through a Pasteur filter, and then heated for fifteen minutes at a temperature of 65° C. in order to destroy the tox-albumens; the fluid was then used as an immunizing fluid, and injected into animals. The animals so treated with one cubic centimetre for a period of five to seven days were found to be perfectly immune to the disease. These experiments were performed four months, I think, before the publication, and at that time they were still immune. In their latest investigation they obtained the same results with the ordinary bouillon culture (without the thymus). So that it is probable that the cholera bacillus, both within the body and in artificial cultures, produces a toxic substance, which may be destroyed by heating to 65° C. for fifteen minutes, and an immunizing substance, which is more resistant. The two may thus be separated and the latter used in the treatment or prevention of the disease.

It certainly looks as though we have here an outlook for the future. These investigators found that the immunity began to show itself after the second day of treatment; so that if the treatment is not too dangerous in man, we shall be able to immunize persons affected in the earliest stages of the disease and thus prevent the fatal results.

THE DIAGNOSIS AND TREATMENT OF CHOLERA.*

By WILLIAM OSLER, M. D.

The diagnosis of Asiatic cholera, easy and clear during the prevalence of an epidemic, may be at its outset (and under the circumstances) exceedingly difficult. The clinical features of the disease and the bacteriological examination of the stools furnish the data upon which to base an opinion.

In the *clinical picture* we are at once confronted with the lack of symptoms distinctive of, and peculiar to, the disease. A case of cholera nostras (morbus) may present every feature of the imported malady; and though it rarely kills with the same rapidity, yet I have known death to follow in an adult within fourteen hours. The preliminary diarrhœa, the vomiting, the copious serous discharges, the collapse, and cyanosis offer no differential criteria.

It is only, however, during "cholera times" that this difficulty becomes serious; and then during the summer months, if the number of cases increases rapidly, it may tax all the resources of our art to reach a positive conclusion. The recent experience in Paris is, in this respect, most instructive. Throughout the month of May, June, and July, an epidemic of choleraic diarrhœa broke out in certain of the suburbs that received polluted Seine water, and more than four hundred deaths occurred. The disease, which was called cholera nostras, choleriform diarrhœa, and cholerine, in many instances killed within a few hours and had all the clinical characters of the Asiatic form; but the persistence in certain localities, without rapid extension, and the freedom of the city proper, encouraged the hope that it was due to intrinsic and not to extrinsic causes.

Dupuy's interesting report from the Hôpital St. Denis describes a disease of abrupt onset, a rapid course, and of great fatality, thirty-one deaths occurring in sixty-five cases. There seems to have been a disposition on the part of the authorities to conceal the serious nature of the epidemic—partly, no doubt, in consequence of the absence at first of positive bacterio-

**Medical News,* Phila.

logic information, and partly owing to the difficulty in obtaining uniformity in the opinion of the physicians, some declaring it to be true cholera, others that it was only a somewhat widespread endemic of cholera nostras.

Since, then, it must be acknowledged that in individual cases and even in local outbreaks, it may not only be difficult, but even impossible to distinguish clinically the two affections, the physician should, from the outset (particularly at the present juncture, when an outbreak may occur), take precautions as if dealing with true cholera, especially, in carrying out disinfection of the stools.

It is of the greatest importance to see cases early, before the symptoms of collapse appear, and people should be instructed to seek advice on the first indication of gastro-intestinal disorder. Dyspeptic conditions and diarrhœa, often premonitory symptoms, give timely warning in many instances, but by no means in all, for an individual may go to bed feeling quite comfortable and awaken during the night with cramps, vomiting and diarrhœa.

It is scarcely necessary to refer to the attacks simulating cholera produced by arsenic, corrosive sublimate, and certain fungi.

Bacteriologic examination is of the first importance, and should be carried out by experts who have critical familiarity with the complex flora of the intestines. Though there are difficulties, the differentiation of the comma-bacillus of Asiatic-cholera can be made, and has been made in the recent outbreaks in Paris by Netter, Chantemesse, and Roux. In all doubtful cases, measures of isolation and disinfection should first be used, and then a thorough examination carried out to determine the presence or absence of the comma-bacillus.

It seems almost an abuse of terms to speak of the *treatment* of a disease of which the mortality is at least 50 per cent.; but although measures are futile in the more malignant cases, there can be no question that prompt action may arrest progress in the less severe forms, while we have at our command the means of alleviating many of the most distressing symptoms.

The ideal treatment would be found in a remedy that, given early, would either control the multiplication of the bacilli in the bowels or neutralize the action of their poisonous products. Several drugs have been recommended for this purpose—salol, particularly on experimental grounds, by Loewenthal; and reports from various sources speak of good results. The drug may be given freely, in doses of from gr. xv to xxx every hour at first, for four or five hours, and subsequently every three hours. It probably acts by retarding the growth of the organism. There is no known remedy that is directly antidotal to the cholera poison. Brunton has advised atropine, to counteract the supposed contraction of the pulmonary arterioles, regarded by Sir George Johnson as the cause of the cyanosis.

The symptomatic treatment should be directed to—

a. Relieving the collapse by hot stimulants, as tea, coffee, brandy, and the external application of heat in various ways. The hot bath should be tried.

b. Checking the vomiting. Cracked ice and champagne, creasote, hydrocyanic acid, menthol, and other means may be tried.

c. Checking the diarrhœa. There can be no question that the collapse is directly due to diarrhœa, and yet it is probably an effort of Nature to get rid of the poison. Indeed, an evacuant treatment has been urged by Johnson, who advises the use of castor-oil; but the general opinion runs strongly in favor of the use of remedies to check the profuse discharges. Various combinations of opium and ether are employed, with or without astringents. Morphine, hypodermatically, is of the greatest value for this purpose, and is to be preferred to opium by the mouth if the vomiting is obstinate. It has the advantage also of quickly relieving the pains and allaying the terrible restlessness. Lactic acid has been strongly recommended by French physicians.

Two special measures may be given a trial, viz.: *hypodermatoclysis* and *enteroclysis*. The former Cantani urges upon the following grounds:

"1. The death of cholera patients supervenes either by asphyxia in the algid period or in consequence of a tumultuous reaction in the tyhoid stage, because the organism, through diarrhœa and vomiting, has lost a very high quantity of its aqueous constituents, and has retained or cannot longer eliminate the excrementitious materials—the products of combustion and decay—on account of suppression of the functions of the kidneys.

"2. Recovery occurs when absorption is resumed, in the intestinal canal, of the fluids which furnish to the blood and to the tissues the water which is indispensable to them."

The formula which he advises is as follows:

℞
Sodium chloride	80 grams.
Sodium carbonate	6 grams.
Boiling water	2 liters.

With a fountain-syringe and the canula of an aspirator, from one to two liters of the fluid is allowed to flow gently beneath the skin of the flanks. The tumor formed by the fluid is slowly rubbed away. He advises the warm bath in conjunction with the infusion. The operation may be repeated in two or three hours.

Enteroclysis is even more warmly recommended by Cantani, a mixture of laudanum and tannic acid being employed. The following is the precedure: "If a slight attack of a seemingly simple diarrhœa does not yield at once to rest in bed and the administration of a dose or two of warm infusion of chamomile, to which chlorodyne or laudanum has been added in proper quantity, then recourse should be had, without loss of time, to the warm enteroclysis of tannic acid. This enteroclysis is essentially an injection into the colon, per rectum, of a considerable quantity of warm water holding in solution a certain percentage of tannin. The rectal syringe, by means of which the injection is made, is furnished with an elastic tube three meters in length, with a nozzle at the free extremity and a cock at the proximal end. With such an instrument not only the whole length of the colon can be filled with the desired fluid, but also not infrequently a quantity can be made to pass beyond the ileo-cecal valve into the small intestine.

"The tannic solution recommended by Cantani is constituted for an adult as follows:

℞
Boiled water or infusion of chamomile, warm	2 liters.
Tannin	5 to 10 grams.
Laudanum	30 to 50 drops.
Powdered gum arabic	50 grams.

"The temperature of the mixture and the quantity to be injected should vary according to the age of the patient and other circumstances, in the judgment of the physician. The most convenient time for administration of an enteroclysis is immediately following an evacuation." (Shakespeare.)

Society Meetings.

The Mississippi Valley Medical Association will hold its Eighteenth Annual Session at Cincinnati, Wednesday, Thursday and Friday, October 12, 13 and 14, 1892. The program is a valuable one, containing many of the most prominent names in the profession our country affords. It covers every department in medicine. The attendance will be unusually large, as Cincinnati is the centre of population of the United States. Not only the scientific, but also the social part of the meeting will be of the highest order. The interest of the Convention will be augmented by the meeting of the gentlemen interested in the Pan-American Medical Congress, also other bodies of medical men. Dr. Benjamin Ward Richardson has written his earnest desire to be present. The Association will be just in time and just in line for many of the gentlemen en route for the American Public Health Association in the city of Mexico. Among the many prominent gentlemen who are expected to read are the following: Dr. Hunter McGuire, Richmond, Va., President of the American Medical Association, the address on Surgery; Dr. Hobart Amory Hare, professor of Materia Medica, Jefferson Medical College, Philadelphia, the address on Medicine. C. A. L. Reed, M. D., President, Cincinnati. E. S. McKee, M. D., Secretary, Cincinnati.

The Committee on Organization of the Pan-American Medical Congress will issue the preliminary announcement within a few weeks. This announcement will show that the organization has been perfected in almost every colony and country of the Western Hemisphere. The local medical societies in each of the constituent countries are made auxiliary to the Congress, which will be held in Washington, D. C., September 5th, 6th, 7th, 8th, 1893.

Dr. Reed, of Cincinnati, Secretary-General of the Congress and Chairman of the Committee on Organization, announces that after extended correspondence between himself and Dr. Maragliano, of Genoa, General Secretary of the International Congress, the date of the Rome meeting has been finally and definitely set for September 24th, of next year. This gives an interval of sixteen days between the Wash-

ington and the Rome meetings, during which time an easy trip can be made from the former to the latter city. It is possible that a steamer may be chartered direct from New York to Rome.

Selected Formulæ.

DISINFECTANT MIXTURES.

The *Sud-Deutsche Apotheker Zeitung*, gives the following:

1. Crude carbolic acid..... 50 parts.
   Iron sulphate..... 25 parts.
   Slaked lime..... 150 parts.
   Calcium sulphate..... 750 parts.
   English red sufficient to color. Powder and mix.

2. Oil of tar..... 50 parts.
   Chalk..... 70 parts.
   Dried bran..... 80 parts.
   Mix.

3. Calcium sulphate..... 15 parts.
   Quicklime in powder..... 10 parts.
   Magnesia..... 10 parts.
   Crude carbolic acid..... 15 parts.
   Infusorial earth..... 7 parts.
   Mix.

4. Quicklime..... 70 parts.
   Charcoal..... 10 parts.
   Crude carbolic acid..... 6 parts.
   Zinc chloride..... 10 parts.
   Hypochlorated zinc oxide..... 5 parts.
   Infusorial earth..... 5 parts.
   Powder and mix.

5. Slaked lime..... 100 parts.
   Coal tar..... 25 parts.
   Infusorial earth sufficient to make a dry powder.
   Mix.

6. Sulphate of iron..... 68 parts.
   Plaster of paris..... 6 parts.
   Calcium sulphate..... 5 parts.
   Infusorial earth..... 5 parts.
   Powder and mix.

7. Iron sulphate..... 3 parts.
   Slaked lime..... 3 parts.
   Turf mold..... 4 parts.
   Mix.

This is especially recommended for privy vaults.

8. Iron sulphate..... 500 parts.
   Plaster of paris..... 475 parts.
   Crude carbolic acid..... 25 parts.
   Mix.

9. Crude carbolic acid..... 2 parts.
   Slaked lime..... 3 parts.
   Turf mold..... 4 parts.
   Mix.

This is the so-called Dietrich disinfecting powder.

SUMMER DIARRHŒA.

For children one year of age:

℞ Zinci sulphocarbolat..... gr. v.
Bismuth subnitr..... gr. xv.
Pepsin saccharat..... 3ss.
Ft. in chart. No. xv. div.....

M. et Sig.—One powder every hour until stools become inodorous; then every two to four hours.

—*Times and Register.*

TREATMENT OF MERCURIAL STOMATITIS.

The *Theräpeutische Monatshefte* recommends the following mouth-wash for mercurial stomatitis:

℞ Tincture of nut-galls.....
Tincture of myrrh.....
Tincture of rhatany āā.....3i. M.
Sig.—This is to be painted on the gums.

As a tooth wash under these circumstances, the following is stated to be useful:

℞ Precipitated carbonate of lime.....
Calcined magnesia āā.....3iv.
Powdered cinchona bark.....3iv.
Chlorate of potassium.....3i.
Powdered rhatany root.....3ii.
Powdered soap.....3vi.
Essence of peppermint.....mxlv.

SULPHONAL-PHENACETIN IN EPILEPTIC INSOMNIA.

—Dr. J. G. Kiernan, of Chicago, reports several cases of epileptic insomnia benefited by the use of the following:

℞ Phenacetin.....gr. xlviii.
Sulphonal.....gr. xlviii.
M. Ut. ft. cap. No. xii.
S. one at 6, 8 and 10 P. M.

A NEW METHOD OF TREATING TUBERCULOSIS, PARTICULARLY SURGICAL TUBERCULOSIS.

Max Schüller, in a pamphlet published in Wiesbaden, 1891, and reviewed in the *Deutsche Zeitschrift für Chirurgie*, Bd. 33, Heft II and III, strongly advises the use of guiacol in tubercular affections. It is given internally and is administered prepared as follows:

℞ Guiacol 5.
Sp. vini rectificat.
Aq. menthae pip. ana 150.
Olei papav. or. ol. jecor. aselli 50.

It is to be well shaken, and a tea to a tablespoonful given four or five times daily. For the past year, the author has been giving the pure guiacol in two to five drop doses in one hundred to one hundred and fifty grams of sugar water. There is also a new preparation, guiacol-carbonate, which may be used. The drug should be give, continuously, for at least eight weeks, and is well born even for months.

In 90 cases of surgical tuberculosis, 70 were healed, 16 improved and 4 died. Locally, surgical treatment is advised to be used in conjunction with the internal administration of the guiacol; thus, in joint diseases the injection of iodoform is to be practiced, and, in glandular affections, extirpation and curetting. The favorable results of the remedy he ascribes to its action on the cells in the neighborhood of the tubercular focus.—*Univ. Med. Mag.*

THE
Medical and Surgical Reporter

ISSUED EVERY SATURDAY

EDITORIAL AND BUSINESS OFFICES:

29-35 N. Tenth St., Cor. Filbert, Philadelphia.

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, OCTOBER 1ST, 1892.

CHOLERA.

The attention of the entire country for the past few weeks has been directed to cholera, from which we have thus far been preserved only by the prompt action of President Harrison and by the severe but just methods adopted at quarantine stations. When we think how many ways the dreaded disease can be introduced into the country, it seems wonderful that we have escaped the epidemic; and now that we have the mistakes committed, fresh in our minds we can draw excellent lessons from our experience of the past few weeks, which will enable us to better battle against the introduction of the plague, both at present—for the danger of its introduction is by no means past—and in the future.

Let us remember "In time of peace, prepare for war," whether that war is against invading armies of foreigners or invading armies of microbes! It is absurd that our country should wait until an epidemic lands in New York, before we make arrangements to handle the disease. Gov. Flower did a good deed when he purchased Fire Island to receive the passengers, and President Harrison acted well when Camp Low was established; but these places of refuge should have been established as soon as the disease was reported in Russia, instead of after the Cholera had reached New York harbor. Let other ports take proper warning and establish places of refuge for the reception of passengers from cholera ships!

The least we say about the shameful and cowardly action of the "clam-diggers" plus the Board of Health of Islip, the better. Their action is a disgrace to modern civilization.

Much complaint has been made against Dr. Jenkins during this critical period, but we should be cautious not to accuse him unjustly. He has shown himself to be a man of iron nerve as well as iron constitution; his official position is an unpopular one, and it would be almost impossible for any man to fill the place at such a time without making enemies. If the statements are true, that the quarantined vessels had difficulty in obtaining fresh water and disinfectants, then something was evidently wrong and some one was to blame for it. Considerable stock has been made out of the fact that dead bodies were allowed to remain upon ships for twelve or more hours after death, but this point can be blamed to the officers of the ships as well as to Dr. Jenkins. When a patient died at Camp Low and the tug was late in coming to take the body away, Surg. Gen. Hamilton lost no time in talk, but buried the body in quick-lime. The

officers of the ships had an equally efficient way of disposing of their dead when the tug failed to take the bodies away. The ships had plenty of coal and immense furnaces. The bodies could have been tied up in the mattresses upon which the patients died, and could have been burned on board. This thought may at first seem horrible, but it is not half so horrible as the thought of allowing the bodies to lie on board ship for several hours.

The ships' officers have in some cases been almost guilty of criminal neglect. It is beyond doubt, that mattresses and pillows were thrown overboard and washed up on shore, and that is totally inexcusable since fires were lighted and these articles could have been burned. It is also beyond doubt that the captain of one of the quarantined ships was on shore for a brief time. Rifle-balls would have been the best thing for a man who so far forgot his duty as this man did.

The action of the quarantine officers in fumigating the luggage of the steerage passengers is certainly to be commended, as it is a practice which can be carried out with good results *not only in time of epidemics but at other times as well.* If it is true, as is stated, that when the steerage passengers were bathed, two or more were obliged to bathe in the same water and wipe on the same towel, then this part of the ceremony should have been omitted since it was worse than useless.

In another column we give several selected articles, treating the subject of cholera from different stand-points. These articles put the matter in a plain straightforward way and are devoid of all minute technical details, at the same time they contain the most important facts upon the subject.

The second annual meeting of the American Electro-Therapeutic Association will be held at the New York Academy of Medicine, 17 West Forty-Third Street, October 4th, 5th and 6th, 1892.

Periscope.

THERAPEUTICS.

TREATMENT OF PLEURITIC EFFUSION.

Dr. Thorongood writes (*Brit. Med. Jour.*, May 28): From such experience as I have had with the salicylate of sodium in cases of pleuritic effusion, I believe it to be often of service. It seems to act by reducing temperature and abating fever; and when this result is brought about, especially in cases of recent effusion, absorption proceeds at once. I have often remarked at the bedside that you do not get a pleuritic effusion to absorb while any inflammation or fever is going on.

In Victoria Park Hospital it has not been an uncommon thing for a patient to be admitted with one chest full of fluid, and after several days' rest this effusion has gradually gone away. I remember how my colleague, the late Dr. Sutton, used to enjoy telling me such cases where a pleuritic effusion vanished under treatment with tinct. cardam. co. ℥ ss, aquæ puræ ℥ j, t. d. s.

Mercury, I believe, limits inflammation in serous membranes, and so promotes absorption. When the absorption commences, the further administration of mercury may often be stopped. For years I have employed mercurials in recent pleurisy, and only once did I salivate a patient. In that case we rubbed mercurial ointment over a blistered surface, and, with some soreness of his gums, the patient recovered quickly.

I have given the tincture of the bryonia alba, a medicine that appears to be a good deal used for rheumatism, being known to all our chief chemists, and I certainly can speak favorably of it as checking inflammatory pleurisy and assisting absorption of fluid. The tincture is usually made according to the form given in the *United States Pharmacopœia.* I am told that the public use the sliced root of the bryonia for rubbing rheumatic joints. Like the salicylate, it is quite one of the antirheumatic medicines.

Before tapping a patient, it is a great advantage to be able to get the temperature down, for then the chance of another collection of fluid is not great. Draw off the fluid rapidly, while temperature is

still a febrile one, go on till the patient coughs violently, show the admiring friends a big lot of fluid, and depend upon it very soon you will be again called in to repeat the operation.

GLYCERIN IN THE TREATMENT OF HEPATIC COLIC.

At the meeting of the Acadèmie de Mèdecine, March 8, 1892, Dr. Ferrand read a paper on this subject, of which the following are his conclusions:—

1. Glycerin administered by the stomach is absorbed as such by the lymphatic vessels, notably by those which proceed from the stomach to the hilus of the liver and to the gall-bladder; it is found even in the blood of the subhepatic veins.

2. It is a powerful cholagogue and a valuable remedy in hepatic colic.

3. In large doses (20 to 30 grammes—5 to 7½ drachms) glycerin cuts short the paroxysm at once.

4. In smaller doses (5 to 15 grammes—1¼ to 1¾ drachms) glycerin taken daily, in a little alkaline water prevents the return of the attacks.

5. Glycerin, although it is not a lithontriptic, is, however, the remedy *par excellence* for biliary lithiasis.—*La France Medicale,* March 11, 1892, p. 174.

THE TREATMENT OF PLEURISY.

In a communication to the French Academy of Medicine, West (*Bull. de l' Acad. de Med.*, xxvii, 3, 14, p. 484) states that pleurisy purulent from the outset is much more common in children less than twelve years old than in adults. If in a case of frank pleurisy with effusion absorption has not begun in the course of eight days, puncture ought to be made. In a large number of cases of purulent pleurisy in children, a single puncture suffices, if care be taken to prevent the entrance of air and if the wound be hermetically closed. It is scarcely possible to puncture too early.—*News.*

ATROPINE AND MORPHINE.

Prof. Unverricht (Dorpat), publishes the following regarding the antagonistic properties of atropine and morphine:

Many practitioners have claimed that atropine is an antidote in morphine poisoning. This suppositon has been disproved by experiments on animals, experiments which Herrback endeavors to explain by faulty work and experimentation. He claimed that it is impossible to arrange the experiments in such a manner as to make the antagonistic properties of these drugs self-evident.

Binz lays special stress on the increased excitability of the center of respiration when atropine is exhibited.

Unverricht had occasion to study a case in which the diminished action of the respiratory centers caused by morphine were not improved by atropine.

Patient had emphysema and degeneration of the heart. He had pronounced Cheyne-Stokes respiration after the injection of 1-6 grain morphine. To investigate whether atropine is able to remove the disturbances caused by morphine, 1-60 grain of atropine was injected into the patient. If then it is true, as supposed, that the Cheyne-Stokes respiration is the result of a diminished action of the respiratory centers, and atropine is able to stimulate this center, then it was to be expected that this symptom would disappear after the administration of atropine. But, as a fact, the very reverse occured. The interruptions of breathing became so very long that a repetition of the experiment was considered dangerous.

The conclusion was then reached that, because atropine augmented the symptoms caused by morphine, atrophine produces the same results in respiration as morphine.

Further experiments showed that atropine if exhibited alone will also cause Cheyne-Stokes respiration. Hyoscine and duboisine had the same action.

Unverricht cautions against the use of these drugs as antidotes in morphine poisoning.—*Centralb. f. Klin. Medezin.*

ARSENIC IN LYMPHOSARCOMA.

After referring to the good effects produced by this drug in malignant lymphoma and the glandular enlargement of pseudo-leukæmia, E. Romberg (*Duet. med. Woch.*, May 12th, 1892) reports the following exceptional case. A man, aged 29, suffering from primary lymphosarcoma of the mediastinum, had secondary deposits, especially in the lymphatic glands and in the skin. In the course of the treatment by arsenic, the tumors of the skin actually disappeared in from two to four weeks'

time. There was no such change in the other growths. The nature of the case was subsequently proved by the necropsy conducted by Birch-Hirchfeld. The author can see no other cause for the disappearance of these growths than the arsenic, and he refers to two other published cases in which sarcomotosis of the skin was apparently cured by the same drug. The author says that the case reported here demonstrates how ill-defined is the division between malignant lymphoma and lymphosarcoma, and how indefinite is the term pseudo-leukæmia. The enlargement of the spleen, the hyperplasia of the tonsils, and the good effect of arsenic, show the above case of lymphosarcoma to be closely allied to malignant lymphoma.—*Brit. Med. Jour.*

THE TREATMENT OF PNEUMONIA WITH DIGITALIS.

Hoepfel (*Therapeutische Monatshefte*, April, 1892), reports fifteen cases of pneumonia treated with infusion of digitalis. Forty-five to sixty grains of powdered digitalis is made into an infusion with four ounces of water, the whole being used in the course of twenty-four hours. He concludes, *First:* That toxic symptoms never occur; where vomiting occurs it can be controlled by the use of strong coffee. *Second*: In all the cases the temperature fell, the dyspnœa, pain, etc., disappeared after one to two days' use of the drug. *Third:* All the cures were shortened from one to three days. *Fourth:* The cures usually ended by lysis.

THE USE OF DERMATOL IN EAR AFFECTIONS.

In the *Therapeutische Monatshefte,* No. 12, for 1891, Davidsohn gives the results of his experience with dermatol in purulent affections of the ear. This substance, which is a sub-gallate of bismuth, has been recommended on account of its absorbent and antiseptic properties. He found it useful in otitis externa, and in many cases of chronic otitis media, but in some cases of acute middle ear inflammation it was not only useless, but became a source of danger from the way in which it formed cakes in the discharge. In two cases of cholesteatoma formation he found it of very good use. In its action he appears to have found it similar to boracic acid.

DUBOSINE SULPHATE.

Dr. Lewald, in "*Der Irrenfreund,*" says that as a sedative in mental diseases this drug has no superior. He has used it in a large number of cases, and finds that its hypnotic influence can be depended upon. It is to be administered subcutaneously, in doses of not more than 0.002 gr., and it is in no case to be increased.

The author thought that if the drug were more widely known the time would not be long before it would supercede hyoscine, as it was more effective and possessed less disagreeable properties.

VESICATION OF THE FOURTH AND FIFTH DORSAL VERTEBRÆ IN THE TREATMENT OF NEUROSES.

Alexander Harkin has repeatedly remarked that in men, as well as in women, who are suffering from various neuroses, the spine, in the region of the fourth and fifth dorsal vertebræ, is sensitive to percussion and pressure; and, basing his therapeutic experiment upon this, he has employed counter-irritation of this sensitive spot, in the treatment of various neuroses, and with success. In several cases of hysteria, trigeminal neuralgia, chorea, paralysis of the facial nerve, reflex vomiting, torticollis, dental neuralgia, occipital pain and pruritus pudendi during pregnancy, the writer has employed this treatment with very good results. It consists in the application of a cantharidal blister and ether to the sensitive spot, the region of the fourth and fifth dorsal vertebræ.—*Wiener medizinische Presse,* No. 6, 1892.

TREATMENT OF PURULENT PLEURISY.

De Gassicours (*Revue des Maladies de l'Enfance,* tome x., February, 1892) reports ten cases of purulent pleurisy treated in accordance with the principles laid down by Breton, seven of whom recovered. One of the deaths was due to diphtheria. In nearly all the cases the pus contained pneumococci, usually in pure cultures. This always should be regarded as a favorable prognostic sign. Both the fatal cases were suffering from tuberculosis. In those cases of pleurisy in which the pneumococci are the causative agents, cure from puncture can be hoped for, often a single puncture being sufficient. Usually more will be required. Three successive punctures should be made, practiced at five days

intervals. If after the third puncture—that is, after fifteen days—pus is found still present in large quantity, formal operation for empyema must be undertaken. When streptococci are found together with the pneumococci, the prognosis is far more serious. Even in this case it is possible that punctures alone may cure, but formal operation is usually required.

MEDICINE.

PHTHIRIASIS OF THE EYELIDS.

Following a communication which Dr. Jullien made to the French Dermatological Society upon phthiriasis of the lids, a number of similiar cases have been published in France, which seems to prove that this localization of the pediculus pubis is less exceptional than was at first thought. All these authors are in accord in recommending as the best method of treatment the patient and careful extirpation of all the parasites and their eggs with dressing forceps, by which means, with a little cleverness, a single seance suffices.

THIRTY-FIVE HUNDRED COMPARATIVE OBSERVATIONS ON THE PULSE, RESPIRATION AND TEMPERATURES OF CHILDREN.

Shufeldt (*N. Y. Med. Jour.*, 1892, liv., 258.) furnishes a paper based upon a careful observation of six children; the pulse, respiration and temperature were accurately taken every morning and evening, and these observations were made comparative with the temperature of the ward noted at the corresponding times, and with such other atmospheric changes in their environment as would be likely to influence the states or other physical condition of the children.

A brief summary of the results showed:

1. The variations in the temperature of a child, both during an attack of rubeola and for a long time afterward, as compared with its pulse and respirations.

2. The effect of the temperatures of the ward in cases of rubeola.

3. A normal curve of rubeola unaffected by treatment, and the course of the temperatures, pulses, respirations, and so forth, for a long time afterward.

4. A long curve of normal temperatures compared with the pulse and respirations, and showing the effect of exercise and atmospheric temperatures on the physical conditions.

5. A curve showing rubeola followed by cholera infantum, with comparisons of pulse, respirations and atmospheric temperatures.

SCIATICA AND VARICOSE VEINS.

Quénu (*Med. Mod.*, May 12th, 1892) expresses the opinion that certain cases of sciatica are due to varicose veins. He states that in people with varicose veins and sciatica, varicose veins are found around the nerve and sometimes adherent to it. A patient who had tried various other measures without success obtained relief for two years by wearing an elastic stocking up to the groin. In two other cases in which the pain had been intolerable, Quénu dissected the veins away from the nerve. The pain disappeared, and has been absent for fourteen months in the one case and four or five months in the other more recently operated on. He looks on the operation of stretching the nerve as a brutal procedure giving by no means brilliant results.—*Brit. Med. Jour.*

EMPYEMA.

Rudolph (*Centralbl. f. klin. Med.*, May 7th, 1892) relates the following exceptional case occurring in a young man, aged 18. On January 5th, 1891 he had a rigor, and then went through a typical attack of acute pneumonia affecting the left lower lobe, the crisis taking place on the 13th. He was without fever until the 23rd, when, after a rigor, he had an equally typical pneumonia of the left upper lobe. On the 28th there was a rapid defervescence, but afterward the temperature became intermittent. On February 16th signs of fluid were found at the left base, and pus was withdrawn by the exploring needle. Incision with removal of a piece of the seventh rib was practiced, and a litre of pus evacuated. On March 2nd the temperature again rose. The abnormal signs still present over the left apex had been attributed to delayed resolution. Exploration in the second left interspace revealed pus. The chest was again incised, and a piece of the third rib removed; 2,000 cubic centimetres of

pus were let out. There was no communication between the upper and lower empyema. The subsequent course of the case was tedious. A sequestrum of bone was removed from the lower wound on June 27th, and the patient was discharged well on September 9th. After pointing to the metapneumonic character of this biloculated empyema, the author observes that the adhesions forming the partition must have arisen during the acute pneumonia, as there had been no previous illness. The strength of these adhesions was remarkable. It is the practice at the Magdeburg Hospital, Rudolph says, to resect a rib, and to wash out the pleural cavity in all cases of empyema.—*Brit. Med. Jour.*

ORCHITIS FOLLOWING INFLUENZA.

Briscoe (*Lancet*, No. 3569, p. 192) reported the case of a laborer, thirty-two years old, in which, after an attack thought to have been influenza, orchitis developed, without other complication.—*News*

RAYNAUD'S DISEASE OF SYPHILITIC ORIGIN.

Dr. A. Elsenberg reports the following case: A patient 22 years old, of slight build, and badly nourished, violent diarrhœa. Examination revealed syphilis. On the body there was a syphilitic eruption; on the forefinger of the right hand, as on both legs, there were isolated dark-brown spots, resulting from cutaneous gangrene, from which exuded an offensive, serous liquid. The soft parts of the toes of the right foot partly, and entirely of the left foot, had become mortified. The patient, after having been one month in the hospital, died, and on post-mortem examination gummata in the liver and atheromatous degeneration in the right arteria dorsalis pedis were found. The microscopical examination of the skin taken from the sphacelated parts showed infiltration in the vicinity of the vessels and sudorific glands, thickening of the walls of the vessels, narrowing of their lumen, in some places entire obliteration, in others proliferation of the endothelium, and even development of small gummata between the endothelium and the middle stratum of the vessel. The author, at the end of his article, arrived at the conclusion that Raynaud's disease may arise from various causes, as in the given case from syphilis, and not, as Raynaud thought, exclusively from a reflex spasm of the vessels.—*Gazeta Lekarska*, No. 5. January 30, 1892.

CARCINOMA OF THE BRAIN SECONDARY TO THAT OF THE BREAST.

Patient was a female aged 41; two children; no history of cancer in the family. On June 11th, 1877, right breast was amputated for scirrhus, the tumor being the size of a hen's egg and situated in the upper part of the breast. No glands could be felt in the axilla. Subsequently there were several small glands removed. Since leaving the hospital patient has suffered from headache, which has been very severe, more severe during the night; absent during the day; referred to vertex and frontal regions. No vomiting, but complains of weak eyes. Is dull and forgetful. General paralysis with rigidity of arms; paralysis has been very gradual in its onset. Ptosis of left eyelid. Necropsy showed the brain to be of normal size; no tumor to be seen externally. Situated in the posterior of the occipital lobe of the left cerebral hemisphere was a large deposit of carcinoma; it was of a considerably firmer consistence than the normal brain substance, was somewhat granular on section and of a grayish-white color; was nearly two inches in diameter antero-posteriorly and the same vertically, and reached the posterior surface of the brain, where it was adherent to the dura mater. The upper limit reached a little above the level of the roof of the lateral ventricle. Another carcinomatous deposit, an inch in diameter, was situated in this hemisphere above the anterior to the Sylvian fissure at Broca's convolution. The points of interest are, as it will be seen, that the tumor occupied what is known as the visual centre in the occipital lobe. Unfortunately the eyes were never very satisfactorily examined, although several attempts were made, but slight optic neuritis existed on the right side—opposite to that of the tumor. The other tumor was situated at what is known as "speech centre"—viz., the posterior fronta of the third convolution, and adjacent parts of the ascending frontal and left cerebral hemispheres, which will account for the loss of speech. There was partial recovery of speech a few days before death, probably due to the right cerebral hemi-

sphere taking on that function. It is worth nothing that loss of speech from disease of the left hemisphere is, as a rule quickly recovered from in children by the compensatory use of the right hemisphere. This takes place in some adults, but in others not.—*Lancet*, Oct., 1891.

ILLUMINATION OF THE STOMACH.

Renvers (*Münch. med. Woch.*, April 12th, 1892) recently demonstrated to the Berlin, Medical Society an apparatus which consists of a small Edison's lamp fixed to the end of a bougie and covered by a small glass case filled with water. The electric current is obtained from a battery of twenty cells. If the stomach is full of food illumination is impossible, but if it is quite full of water when the lamp is passed into the stomach an illuminated area is seen which corresponds exactly to the limits of the organ. The apparatus can only be used in the erect posture, when the greater curvature is usually seen a little below the level of the umbilicus. Abnormal dilatation of the stomach can be readily detected, and a case of carcinoma of the organ has been diagnosed by the use of this apparatus, the diagnosis being confirmed by *post mortem* examination. The tumor appeared as a dark spot in the light field.—*Brit. Med. Jour.*

TREATMENT OF TABES-DORSALIS.

Leyden (*Berl. klin. Woch.*, 1892, Nos. 17 and 18) first refers to the drugs most commonly employed. With regard to mercury, he would not oppose its use, but he rejects altogether the syphilitic origin of the disease. Many of the cases which have got well under mercury have been examples of peripheral-neuritis. The treatment by baths sometimes yields good results. Electropathy is, in the author's opinion, a valuable method of treatment, but massage can have but little effect. Leyden does not believe much in suspension, nor in nerve-stretching, nor yet in the orthopædic treatment. He lays considerable stress on what is called the compensatory treatment of this disease, namely, that when the disease is incurable, the disturbance of function should be minimized as much as possible. In tabes-dorsalis the ataxy is one of these disturbances, and this may be in great measure compensated by the use of gymnastic exercises. The very valuable paper by Fraenkel (*Münch. med. Woch.*, 1890, No. 52) on the use of these graduated exercises in disordered co-ordination is referred to. Under the head of complications the pains and gastric crises are chiefly alluded to. The author cautions against the indiscriminate use of morphine. The loss of weight often occurring rapidly if the gastric crises last long, must be counter-balanced by good feeding in the intervals. The avoidance of over-exertion, exposure to the weather, and excesses of all kinds is naturally insisted on.—*Brit. Med. Jour.*

GONORRHŒAL CYSTITIS.

Much controversy has arisen in regard to the real existence of specific gonorrhœal cystitis. Du Mesnil holds (Virchow's *Archiv*) that there is no such thing, and states that when gonococci are present in the urine they have, in all probability, come from urethral pus, and are not products of a true specific inflammation of the vesical mucous membrane itself. In women, he says, pus might easily get into the bladder from the urethra or the vagina, and maintains, on the strength of recent researches, that gonococci have no effect on the composition of the urine, and that cystitis with ammoniacal urine is not produced by these bacteria. On the contrary, it is held that the urine renders the gonococci harmless, or even kills them entirely.—*Merck's Bulletin*, May, 1892, p. 286.

SURGERY.

RESECTION AND SUTURE OF THE URETHRA.

Jouon, of Nantes (*Sem. Méd.*, May 4th, 1892) reports a case of rupture of the urethra followed by urinary abscess and considerable induration of the tissues, which he treated successfully by resection and suture. The resected segment measured ten millimetres at the upper and eighteen millimetres at the lower part. The cut surfaces were brought together with nine fine catgut sutures. The immediate results of the operation were per-

fect, and Jouon thinks that the method should be applied to all undilatable sutures, whatever their origin. Quénu (*Sem. Méd.*, May 11th, 1892) has resected the urethra with indifferent success. The patient was a horseman who had sustained a traumatic rupture of his urethra, and during a period of ten years had undergone internal urethrotomy five times and dilatation on several occasions. The man was in a wretched state, the urine being purulent and ammoniacal, and the bladder the seat of infective lesions. Resection of the strictured portion of the urethra was performed, one centimetre and a-half being excised. A fistula was left, however, and the condition of the urine was but little improved, and Quénu thinks it probable that this was the cause of the failure of the operation. In any future similar case he proposes to prevent the infection of the operation wound by the urine by first making a provisional buttonhole opening in the membranous portion of the urethra. Desprès (*ibid.*) points out that resection of the urethra is not a new operation, having been practiced by Bourguet, of Aix. He thinks suture unnecessary after resection, as healing takes place by granulation when a catheter is tied in. In this way he cured a patient with a strictured and fistulous urethra, two centimetres of which he resected. The fistula left by the operation closed spontaneonsly in a few months.—*Brit. Med. Jour.*

CURETTING OF THE LACHRYMAL SAC

Dr. F. Despagnet urged this before the Congrès Français d'Opthalmologie (*Recueil d'Opthalmologie*, ann. xiii., No. 5), his conclusions being that: Whenever the overflow of tears arises from catarrh of the lachrymal sac (this being the most frequent cause) the alteration of the mucous membrane was the principal factor, and by catheterizing and the injection of astringents the attempt should be made to modify this. If this treatment, practiced through a greater or less period, does not produce the desired result, curetting of the mucous membrane is the operation to be chosen, because it attacks directly and without complication the diseased part and allows the preservation intact of the lachrymal excretory apparatus. If the epiphora coexists with great dilatation of the sac, the curetting should be preceded by the excision of a portion of its anterior wall. Curetting is also indicated in the case of abscess in the sac.—*Amer. Jour. Med. Sci.*

A NEW TREPHINE.

Tauber describes a new form of trephine, by means of which a disc of bone in the shape of a truncated cone can be removed from the skull. The advantage claimed for this shaped button is that on replacing it the level of the skull is preserved, that is, the button does not tend to fall in, also its margin is in close contact with the hole from which it was removed. The author believes that with this instrument, a surgeon may safely remove a series of dics and thus expose a large extent of the surface of the brain. The openings which are not united may be immediately filled up with every confidence of complete closure by speedy osseous reunion.

EXCISION OF AN ŒSOPHAGEAL DIVERTICULUM.

Von Bergmann, of Berlin reports (*Arch. f. klin. Chir.* Bd. 43, Heft 1) the following case, which he believes to be the first in which extirpation of an œsophageal diverticulum has been performed. The patient was a woman aged 38, who for four years had suffered from disordered digestion. She vomited all food almost immediately after taking it, and could feel her neck become thicker as she swallowed. The sound passed sometimes with perfect ease, and at other times was arrested a little way down. As nutrition was seriously affected, and as the prognosis of such cases is bad (13 deaths in 21 cases), Von Bergmann determined to attempt excision of the pouch. A long incision was made along the anterior border of the left sterno-mastoid. The deep cervical fascia was next divided, and a large goître, which seriously hampered the operator, partly separated from its attachments and turned aside. The superior and inferior thyroid arteries, and several veins were tied. The retro-œsophageal space was now exposed, and after a little search the diverticulum was found and freed from the surrounding tissue with the handle of the knife and forceps. It could then be seen hanging from the gullet

like a small pear. It was removed, after which the mucous membrane of the œsophagus was brought together with stitches. The lower part of the operation wound was closed with sutures, the remaining portion being plugged with idoform gauze. Although the patient had a drink immediately after the operation, the œsophageal wound healed by the sixth day. A small fistula which remained closed up after a few applications of the galvanocautery. The wound in the neck then healed up by granulation without further trouble, and the patient was completely cured. As the pouch had a muscular covering on the outer surface, and as the patient had probably suffered from a cervical fistula in infancy, von Bergmann thinks the diverticulum was congenital in origin.—*Brit. Med. Jour.*

AURAL CATHETER STEAM STERILIZER.

Bark, *Journal of Laryngology, Rhinology and Otology*, July, 1892., states that the instrument consists of a metal globe, to which is attached by means of a screw a bent tube with a conical nozzle covered with rubber tubing. A small metal ring is attached to the globe for the purpose of holding it. The globe is then half filled with water, and the bent tube screwed firmly down. The large end of a catheter is then placed upon the nozzle, and the globe held over the flame of a spirit lamp. A powerful steam jet is in this way forced through the catheter, thoroughly cleansing it. The catheter is then immersed in some antiseptic fluid.

FRACTURE OF THE BASE OF THE SKULL.

Dr. Leopold Schiller reports the case of a laborer. While lowering, by means of a rope, an iron column, was struck above the right ear by a swinging column and thrown on his head against a four-by-four beam. Became unconscious. There was a severe scalp wound, bleeding from both ears, nose and mouth, and there was paralysis on both sides of the face and fauces. Bilateral lagophthalmus and a convergent squint of the left eye, the pupil of which was larger than that of the right and sluggish in action. Severe headache, which continued five or six days, but gradually disappeared. Sensation of dizziness which lasted several weeks. Right side of face soon began to regain mobility, and in three weeks patient was able to close right eye and wrinkle forehead on right side. Left side showed no sign of improvement, but later regained considerable mobility. Strabismus disappeared, but still had dizziness and ringing in the ears, also slight parasthesia of the tongue.—*Med. News*, Mar. 5, 1892.

DERMATOL IN SURGICAL PRACTICE.

At a meeting of the Spanish Medico-Chirurgical Academy, Azna (*Revista de Med. y Cir. Pract.*, March 7th, 1882) gave an account of his experience of dermatol in surgical practice. Even when employed in large quantities he said it does no harm; it stimulates granulations, and is particularly useful in skin affections, such as eczema, which are characterized by much discharge and if dermatol is applied to the wounds which have already begun to granulate it greatly stimulates the process, and similarly in the case of soft chancre after the ulcers have been cleansed with antiseptic lotions, dermatol hastens repair, and brings about rapid and thorough healing.

In diseases of the skin Azna things that dermatol, with its drying and astringent properties, its absolute harmlessness, and the ease with which it can be used, may advantageously replace starch powder, oxide ef zinc, etc.

It is also useful in the affections of the female genitals.

THE MECHANISM OF CONCUSSION OF THE BRAIN.

In *Brain*, part i of volume xiii, there is a paper by Dr. Alexander Miles supporting and confirming the conclusion published by Duret, that the group of phenomena commonly spoken of as "concussion of the brain" is the result of a temporary anæmia of that organ. This anæmia is the reflex result of stimulation of the restiform bodies, and perhaps of other important centers in the region of the bulb, produced by the wave of cerebro-spinal fluid which rushes through the aqueduct of Sylvius and the foramen of Magendie from the subarachnoid space of the brain to that of the spinal cord when a severe

blow is dealt over the skull. In accordance with the laws of hydrostatics this cerebro-spinal wave will disturb the equilibrium of the ultimate nerve cells throughout the central nervous system. The hæmorrhages found throughout the brain substance and on its surface are to be ascribed to the recession of the cerebro-spinal fluid, which naturally supports the blood-vessels of the cerebrum. These petechial hæmorrhages are not the proximate cause of the symptoms of concussion, but are rather to be looked upon as an index of the force that produced the injury.—*N. Y. Med. Jour.*

A SIMPLE METHOD OF TREATING MANY CASES OF LACHRYMAL OBSTRUCTION.

Dr. George M. Gould (*New York Medical Journal*, June 4, 1892) gives his method as follows: "First empty the sac and canaliculi by dexterous pressure, and cleanse the eye and palpebral pockets of this unhealthy material, (water, mucoid and purulent.) Then cast the patient's head back and to one side, or have him lie so that a teaspoonful of liquid will be held in the depression formed by the nose, orbital border and superior maxilla. Fill this space with a solution of boric acid, and with the little finger again empty the sac and canaliculi by pressure, and then as slowly lessening the pressure, allow these spaces to refill, by suction and capillary attraction, with the solution under which the puncta are submerged. Again in half a minute empty the canaliculi and sac by pressure, but this time beginning the pressure from the canthus toward the nose and downward, so as to force the antiseptic solution downward into the duct. These emptyings and refillings of the sac may be repeated several times and as often as desirable to meet the indications of the case. It will be usually found that the sac will soon become healthy, and that pressure upon it will not cause regurgitation of morbid material through the puncta."

The solution which Gould uses is composed as follows: "To the ounce of distilled water; of boric acid, ten grains; common salt three grains; chloride of zinc one grain—all deeply tinted with pyoctanin-blue, and doubly filtered after long standing."

Gould adds: "A certain number of cases will not yield to this treatment. There is too great stenosis of spasmodic contraction of the muscular sphincter of the punctum, etc., so that the cleansing solution cannot be forced into the sac and duct. In such cases I am accustomed to insert one sharp point of the iris scissors into the punctum and snip it open one eighth of an inch, perpendicularly downward toward the conjunctival fold. This gives a larger opening for the indrawal of the solution."

Gould states that he is astonished to see how rapidly cases recover under this simple treatment, that formerly would have seemed to demand slitting of the canaliculus and probings."

RUPTURE OF THE BLADDER.

Schlange, in the *Archiv für klinsche Chirurgie*, Bd. 43, H. I., discusses the treatment of rupture of the bladder, and gives the history of a case. He collected 32 cases treated by operation. In 22 of these the rupture was intraperitoneal, of which 10 recovered and 12 died. Of the remaining 10, 7 were cured and 3 died. His own case was as follows: A man aged 34 years, was run over by a wagon, the wheel passing over the abdomen, the bladder being at the time distended. He was brought to the hospital the next day. His breathing was shallow and pulse rapid. The abdomen was distended, and desire to urinate and pain were marked. The catheter only withdrew a few drops of bloody urine. On operating, the prevesical tissue was found infiltrated with bloody urine; the bladder was darkly colored, collapsed, and contained a few blood-clots. On the left side, posteriorly, near the prostate, was a tear five cm. long, and connecting with it, a cavity between the rectum and bladder. Another and somewhat larger tear was found in the apex of the bladder. The abdominal wound was enlarged up to the umbilcus, another cavity containing bloody urine being opened in so doing. Irrigation was not employed, as the extravasated urine was regarded as being only a chemical irritant and not of an infective nature. The posterior opening in the bladder was closed with catgut sutures and the edges of the interior one sewed to the skin. The cavity of the bladder was loosely filled with gauze, one end being brought out of the wound for drainage.

The subperitoneal cavities were tamponed with gauze. In fourteen days the tampons came away and the wound granulated shut—the man remaining permanently cured.—*Uiv. Med. Mag.*

PEDIATRICS.

GLYCERITE OF BORAX IN INFANTILE DIARRHŒA.

G. Mansal Simpson reports in the *Lancet*, April 1892, his experience in the treatment of infantile diarrhœa, by means of glycerite of borax. Glycerine and borax, both possessing antiseptic and soothing properties, soon correct the fermentation of the contents of the alimentary canal, the stools soon losing their offensiveness and becoming normal. The ordinary dose for a child is about 20 minims, administered every two or three hours, according to the severity of the symptoms. The medicine should be diluted with water, and may be flavored to suit.

THE TREATMENT OF INFANTILE DIARRHŒA OF WARM COUNTRIES.

Dr. F. Roux divides the diarrhœas into four classes: 1. Simple catarrhal enteritis, frequently developed by cold, requires only rest, restricted diet, soothing applications to the abdomen, and graduated doses of paragoric. 2. Diarrhœa dependent upon digestive insufficiency, requires a small amount of magnesia in a half-glass of Vichy (St. Yorre) as a purgative, a milk diet, and soups devoid of fat. If the stools are offensive, a powder consisting of equal parts of the salicylates of bismuth and magnesia; naphthol being here contra-indicated because of the irritation which it produces. The return to the ordinary diet must be gradual, and before each meal he directs small doses of nux vomica, rhubarb, anise seed, and calumba, in a claret glass of Vichy or Vals. During the meals hydrochloric acid, and afterward pepsin, diastase, and pancreatin. He counteracts diarrhœa and vomiting by opium, the constipation by rhubarb. 3. The diarrhœa that follows dysentery calls for enemata of boric acid, nitrate of silver, or tincture of iodine, and the prescribing of a strict diet. 4. In true tropical diarrhœa the small intestine is the seat of disease, and it is necessary to insist upon intestinal antisepsis, salicylate of bismuth, sulpho-carbonated water, enemata of boric acid, or, better, of borated infusion of eucalyptus, with abdominal counter-irritation, as by tincture of iodine, or gentle friction with flannel moistened with turpentine. The only method of satisfactory cure consists in an absolute milk diet, to which is added lime-water or Vichy salt. As soon as the stools are formed, beef-tea, peptones, slightly cooked white of egg, raw beef, eggs and milk, and, last of all, rice in milk can be tried. At all times remedies which assist digestion must be employed, while wine and every form of alcohol is absolutely prohibited. When the disease is cured, it is necessary for a long time to watch over the diet, and use remedies that build up the general condition.—*Amer. Jour. Med. Sci.*

TRACHEOTOMY STATISTICS AT L'HOPITAL DES ENFANTS-MALADES SINCE 1886.

Year.	Number of Tracheotomies.	Died.	Cured.	Proportion per cent.
1886.....	356	297	59	16.57
1887.....	365	307	58	15.89
1888.....	360	310	50	13.88
1889.....	261	202	59	21.60
1890.....	296	227	69	23 27
1891	256	175	81	31.64

These statistics show at a glance, notwithstanding the absence of details, the increase in the proportion of recoveries during the last three years. This statement was prepared by Mlle. Deaussoir, Superintendent of the Diphtheria Pavillion, to whose care is owing in no small measure the improvement noticed in the statistics.

As is known, the service in this pavillion passes every three months to the different members of the Visiting Staff in turn, whose methods of treatment vary necessarily; moreover, no mention is made of the different topical applications employed. But, whatever application is used locally, the tonsils and pharynx are always cleansed with the greatest care. Tracheotomy is performed on the upper portion of the trachæ without chloroform. —*Revue des Maladies de l'Enfance*, May, 1892, p. 229.

INSOMNIA IN AN INFANT.

If there exists in the literature any record of real insomnia in very young infants, the fact has escaped my observation. The natural tendency of early infantile life is

to spend itself mostly in sleep. The neurologically healthy babe during the first few weeks of its extra-uterine life is kept awake just as it is caused to cry by some unpleasant or disagreeable excitation. Much of the first six weeks of its existence out of the mother's womb is passed in sleep, A sleepless babe, not subjected to sufficient corporeal pain or irritation to provoke crying, is an anomaly. Yet such is the fact which I have to record of a female infant, five weeks of age, who, without physical or mental provocation, would lie awake with eyes wide open and gaze about in placid contentment throughout the night, unless sleep were induced, as in the more aged, by hypnotics. The child was quiet and tranquil and free from pain or other source of bodily discomfort.

It was well cared for by a faithful and intelligent nurse. Its napkins were always dry and soft, the umbilical cord had separated and the naval had healed, having been carefully dressed with simple cerate and patent lint; colic and constipation had been carefully guarded against. The babe nursed well, the mother had sufficient milk, and its evironments were all favorable to rest and sleep, yet it slept not for several nights and not then until after receiving treatment for insomnia, as an adult would, only in proportion diminished to suit its age.

This insomnia would recur if the treatment were omitted, until about the end of the tenth week. The child then slept without medical assistance and became a vigorous and neurotically tranquil babe.

Sleep was only induced by five-grain doses of bromide of sodium and three-grain doses of chloral put into a small amount of milk and given the babe from a bottle. the chloral once at night and the sodium salt twice or thrice daily for a brief period. Celery and catnip teas and the hypophosphites were also given freely.

This child's mother had been much excited, mentally and nervously, verging on mental aberration, during the period of gestation and before, and required the skill of a practised alienist to avert a puerperal psychical climax after the birth of this infant. The mother was given hypnotics and the bromide salts quite freely during the first few weeks after the birth of the child, which may account for the insomnia not having appeared earlier as a hereditary condition, as it appears really to have been. To my mind, the mother's neuropathic condition before and after the birth and at the time of conception, explains the state of the child. Before the insomnia was arrested some slight chorea became manifest, but this disappeared with the restoration of normal sleep and neural recuperation and central nerve stability.—Dr. C. H. Hughes, in *Alienist and Neurologist.*

HYGIENE.

THE DANGERS OF READY-MADE GARMENTS.

No term, perhaps, possesses a more familiar meaning than the word "parasite." Happy, indeed, would be that animal which, however unconscious of etymology, had not the most intimate relation with it. It seems an almost hopeless task to search for this enviable creature. We should despair of finding it even among the animalcula or in the cell world of histology.

> "So, naturalists observe, a flea
> Has smaller fleas that on him prey:
> And these have smaller still to bite 'em,
> And so proceed *ad infinitum.*"

It is not numbered with the greater beasts. It is not man, whether of high or low degree. The Scottish poet describes, in a humorous poem which is frequently quoted for the pointed lesson it conveys, the career of one well-known parasite which he observed, "plump and gray," strutting on a lady's bonnet at church. A correspondent writing in a somewhat similar vein, confesses to a like experience. She dilates upon "some exceptionally dainty and befrilled hand-made *lingerie,* snowy, spotless, crisp, and garnished with lace," but, she pathetically adds, with "a something half hidden under a tuck." It was, in her servant's *patois*, a "death louse." Need we be surprised that our correspondent adds to her graphic description the warning that all bought underclothing should before wearing be made to undergo "the full laundry process," the more especially since it appears to be quite customary (may the custom early become extinct!) for firms to send even such articles "on approval" to be tried on? What possibilities does this practice open up, not only of parasite migration, but of

the actual communication of disease. It is a veritable method of infection and it has doubtless acted as such more often than we are aware of. The only real remedy, of course, consists in its entire discontinuance. Less than this ought not to satisfy a wholesome public opinion. Until, however, the usage of trade in this particular is above suspicion a careful examination and free ventilation of all purchased clothing should not be omitted, while such further measures as "the full laundry process," and, beyond this, antiseptic fumigation, can never be superfluous.—*Lancet.*

DISINFECTING FOOD.

The Governor-General of Kiév appointed committees last fall to gather the morsels that are left on the table after meals in the large cities, and to send them to the famishing peasants. A large portion of this food comes from communal institutions, such as casernes, hospitals, and from social repasts. The question arose whether it would be possible to disinfect these fragments so that the contagious diseases of the eaters who left them on the table might not be conveyed to the beneficiaries without at the same time destroying the food. The question was referred to the Bacteriological Institute of Odessa, and the following instructions were received in reply: "Morsels of bread left over by persons infected with diphtheria, typhoid, or other contagious diseases, become perfectly disinfected if dried at a temperature of 250° F. But if such a degree of heat cannot be obtained in the drying process, the morsels, before drying, must be submitted to a current of steam of that degree for at least one hour."

THE DISINFECTING POWER OF LYE.

According to the *Revue d' hygiène* for January 20, 1892, Dr. A. Montefusco and Dr. O. Caro have published (*Rivist. internaz. d'igiene*, 1891, fasc. 10, 11) a paper on practical, domestic, and economical disinfection by ordinary lye. After an immersion of twelve hours in a solution of boiling lye, cholera and typhoid bacilli and charbon spores were invariably destroyed. If the solution was kept at a temperature of 20° C., sterilization resulted in in six hours; at 50°C., one hour's immersion produced sterilization; the spores of charbon were not destroyed in one, two, or less than six hours at a temperature of 100° C., whereas in that time the same result was obtained at a temperature of 25° C. The alkalinity of a litre of this solution of lye was exactly neutralized by 315 cubic centimetres of a normal solution of pure oxalic acid. Frequently in Naples and at many Italian hotels linen is bleached by immersion in a solution of lye that requires 500 cubic centimetres of a normal oxalic-acid solution to neutralize it. The destruction of bacilli is equally assured by six hours' immersion in this liquid prepared for domestic use. Gerloczy, of Buda-Pesth, published a paper some years ago recommending lye as a microbe destroyer for fæcal matters; and recently Schimmelbusch and Behring have confirmed his results in experiments made with various micro-organisms.

EARTH-WORMS AND TUBERCULOSIS.

Dr. Lortet and Dr. Despeignes have published (*Lyon Médical*, No. 29, 1892) a report of their investigations regarding the possibility of earth-worms carrying to the surface tubercle bacilli from inhumated corpses, as Pasteur has shown they do with charbon spores. Tubercle bacilli in sputa and sections of tuberculosis organs were buried in the soil of large flower-pots in which several worms were placed. At the end of some months the worms were removed and inoculated in guinea-pigs, which rapidly succumbed to acute tuberculosis. The organs of the worms contained tubercle bacilli, although no lesion was apparently produced by their presence. These results seem to show an additional desirability of cremation.

CONTAGIOUSNESS OF ACUTE TONSILITIS.

Acute tonsilitis is now considered a general disorder from the beginning infectious, and probably of microbic origin. In certain cases infection is manifested by visceral complications (purulent pleurisy, albuminuria, etc). The pus of tonsillar abscesses contains staphylococci and streptococci. In acute superficial tonsilitis the intensity of the fever, prostration and tedious convalescence, militate in favor of infection. The author has noted several cases of acute sore throat following in about eight days, the appearance in the

waiting-room of the "throat" department of the hospital, of a case of tonsilitis. There had been no previous cases for a long time. These facts seem to prove its contagiousness, although this is not the sole means of the spreading of the disease.

He considers that antiseptic treatment should be instituted and the predisposed persons should be removed from the locality.—Richardiere, *Rev. de Laryngol. d'Otolog., etc.*

MEDICAL CHEMISTRY.

REAGENT PAPERS FOR URINE TESTING.

The pharmacist may do his physician friends a service at but slight expense to himself by preparing and keeping on hand reagent papers for testing urine for albumin. These are made of good thick filter or blotting paper, as follows: Saturate a sheet of paper with a concentrated solution of citric acid, and let dry. Saturate another sheet with a 3-per-cent solution of corrosive sublimate in a twelve-per-cent solution of potassium iodide (mercuric chloride 3, potassium iodide 12, distilled water 100 parts. Dissolve the potassium iodide in the water, and afterward add the chloride, and dissolve.) Dry this sheet also, and cut both sheets into strips two inches long by one-half wide. Put them up in separate packages and label one "acidifying paper," and the other albumin test paper. In use first acidify a small amount (say 1 ccm.) of the urine with the acidifying paper, then add the test paper, and shake. If albumin be present in a greater proportion than 1:10000 it will manifest itself by separating in flocculent masses.

SPURIOUS SALOL.

It appears that recently some spurious mixtures have been retailed as pure salol. The pure article is found to be readily identified by placing a few drops of nitro-sulphuric acid in a watch-glass and adding a little salol powder. The mixture soon takes a yellow color and, on being stirred about with a glass rod, this color passes to brown, and then to green. As soon as this coloration has been noticed, the watch-glass and its contents are placed in a porcelain measure with about three-quarters of an ounce of water, and the mixture shaken up. The liquid then takes a rose color, and the green color again appears if ammonia is added to the liquid. When resorcin is treated exactly in the same manner, the mixture becomes immediately of a very dark blue color. If then it is treated as above with water, a red color derived from resorcin, is produced, but by the addition of ammonia, it turns blue and not green, as is the case with salol.—*American Lancet.*

RAPID AND ACCURATE METHOD OF DETERMINING FAT IN MILK.

The following paper on this subject was presented by Dr. Henry Leffman and Dr. W. Beam, of Philadelphia, to the Society of Public Analysts at a recent meeting held in London:

Among the processes for the rapid determination of fat in milk, those employing centrifugal machines have been most satisfactory. A procedure devised by us has proved, in the experience of others as well ourselves, rapid, accurate and economical.

For the test we employ a bottle holding about 30 cc., the neck of which is graduated so that a volume of 1½ cc. is divided into 86 equal parts. Fifteen cc. of the milk being taken, each of these represents 0.1 per cent. by weight, of butter fat. The test is made as follows:

Fifteen cc. of the milk are put into the bottle, 3 cc. of a mixture consisting of equal parts fusel oil and strong hydrochloric acid are added, mixed, and strong sulphuric acid poured in slowly, with agitation, until the bottle is filled nearly to the neck.

The liquid becomes hot and the casein is completely dissolved, a dark reddish-brown solution being formed. The neck is filled to near the zero point with a hot mixture of sulphuric acid and water, and the bottle whirled in the centrifugal machine for from one to two minutes. Milk very poor in fat may require from three to four minutes. The volume of fat which rises in the neck can be read off directly or by the use of a pair of dividers.

The points of these are adjusted at the upper and lower limits of the column of fat, allowance being made for the meniscus; then the dividers being placed so that one point coincides with zero of the scale, the exact volume can be read off. If but one test is to be made it will be necessary,

of course, in order to preserve the balance of the arms of the machine, either to make duplicate mixtures or to fill the other test bottles with diluted sulphuric acid.

We give herewith the results of comparative tests with the Adams method, care being taken that the paper used was free from any extractable matter.

The bottles employed in these tests were divided into 100 parts, and the figures here given were obtained by multiplying by the factor 0.86. (As noted above, we now use a bottle divided into 86 parts, and thus save calculations.)

SKIMMED AND WATERED MILK.

No. 4.	0.56	0.51 0.51

Another determination was made of sample No. 4 by boiling down to one-half volume and treating by the method, the results being calculated to the original volume. This gave 0.55 per cent of fat.

Tests were made to determine the effects of longer rotation in the examination of milks poor in fat. Thus, by four minutes' whirling the last sample gave, with previous concentration, 0.55 per cent of fat.

Comparisons have also been made between the results of this method and the figures for fat as determined by calculation from the specific gravity and total solids, basing the calculations on the Hehner and Richmond tables, and the results of the comparisons are tabulated below:

Sample.	Fat by calculations H and R.	Fat by centrifugal method.
No. 5.	3.60	3.61
No. 6.	4.15	4.10

We find as a result of many tests, that with bottles accurately graduated, and reasonable care in manipulation, especially sufficient rotation, results will be obtained within 0.1 per cent of those of the standard methods.—After *The Analyst*.

NEWS AND MISCELLANY.

CARRIER-PIGEONS AND VACCINATION.

At the last meeting of the Academie de Medecine, Dr. Hervieux, who presides over the Public Vaccination Department at the head-quarters of that learned body (vaccinations from the calf are performed gratuitously at the building in the Rue des Saints-Péres every Tuesday, Thursday and Saturday) read a report by an army surgeon, M. Stroebel, on the transport of vaccine by carrier-pigeons. It appears that one pigeon is capable of conveying in one journey from five to six tubes. The utility of this means of transport in times of war is very obvious, and one can imagine the joy of the representatives of the Army Medical Department at the apparition of a flock of these swift vaccine carriers in a besieged town.—*Lancet*.

THE BACILLUS OF SOFT CHANCRE.

About three years ago *La Riforma medica* published a description by Dr. A. Ducrey of a microbe that he had found in soft chancres, and that he regarded as the cause of that disease. He inoculated, with antiseptic precautions, pus from soft chancres in a series of five or six subjects. While the sores resulting from the first inoculations contained numerous microbes, he did not find more than a single one in the last. The bacillus was short and thick, having rounded extremities, often with a lateral groove, and was either isolated or in chains. He was not able to cultivate it in any of the media employed in the laboratories.

In the June number of the *Annales de Dermatologie et de Syphilgraphie*, Dr. Pusey reports the discovery by Dr. Unna of a bacillus that seems to be the pathogenic agent of the soft chancre. It occurs in the form of chains of two or more bacilli, and is most numerous in ulcerated tissue, though it is found between the cells of the environing tissue. It may be isolated in microscopic preparations by coloration with methylene blue, and then declorized with stryone or ether and diluted glycerin.

This is the only bacillus encountered, and Unna has found it in every soft chancre excised and examined by him. It is found in the tissue alone, unassociated with other microbes, being distributed in a

peculiar manner, and it is not found in simple ulcers or in initial indurated sores. Apparently no effort has been made by Unna to cultivate this organism, or to demonstrate its pathogenic character by inoculation. Ducrey's inoculation experiments were a repetition of the oft-repeated experiments of inoculating the pus of a soft chancre, and they can not be regarded as demonstrating the pathogenic character of the micro-organism be found. In a recent number of the *British Medical Journal* there is a note stating that Quinquaud has confirmed Unna's discovery, having found a bacillus present in prodigious numbers in the lymphatics and intercellular spaces. The question is well worth further investigation, if only to demonstrate that the micro-organism causing soft chancre is but a more virulent form of some well-known bacillus.—*N. Y. Med. Jour.*

THE CONGRESS OF TUBERCULOSIS IN 1893.

According to the *Revue General de Clinique et de Therapeutique* for July 13, 1892, the following questions are to be discussed at the Congress of Tuberculosis in July, 1893: 1. The respective rôles of contagion and heredity in the propagation of tuberculosis. 2. Infectious diseases as agents provocative of tuberculosis; the rôle that is played by certain of them in the localization of tuberculosis, such, for instance, that of gonorrhœa in the development of tuberculosis of the testicle, and that of grippe in the development or aggravation of pulmonary tuberculosis. 3. Remissions in tuberculosis; the duration of these remissions; the methods of recognizing them and of preventing their cessation; the causes of recurrence. 4 The various methods of diagnosticating bovine tuberculosis, especially in determining if inoculation is a sure and certain method of establishing the diagnosis of tuberculosis in cattle. 5. The dangers that may follow the inhumation of tuberculous corpses; the opportuneness of substituting cremation for inhumation; the necessity of destroying the tubercle bacilli in corpses. 6. New methods of prophylactic and curative treatment of tuberculosis, based on its ætiology. 7. The utility of a general inspection of meat. A prize of $600 (3,000 *f.*) will be given for the best work on the question of "The methods of diagnosticating latent tuberculosis before its appearance or after its cure."

THE MORAL SIDE.

In an address before the Marion-Sims College (*Alienist and Neurologist*, July, 1892) Dr. C. H. Hughes says:

The study of the physician includes the moral as well as the physical well-being of man, for the purity of the soul has much to do with the health of the body. The purity of the heart and the dominance of the body by principles of rectitude has much to do with the health and consequent happiness of present and succeeding generations. The direct and hereditarily entailed diseases which are the offspring of sin, and *vice versa*, which have filled and are filling the land with misery and woe, both physician and divine are alike especially interested in preventing. The psychology of sin and the pathology of crime are studies alike for doctor and divine.

The man who is sick in his soul is seldom well in his body, and the soul's affairs do not prosper well when the body is disordered.

Like the divine, the physician may also aid in healing "the wounded in spirit and the broken-hearted," and in "binding up their wounds." He may "minister to a mind diseased," and "with sweet oblivion's antidote cleanse the stuffed bosom of that perilous stuff which weighs upon the heart." He does this effectually through the modern successful management of melancholia.

SIR JOSEPH LISTER.

The retirement of Sir Joseph Lister from his post as Lecturer on Clinical Surgery at King's College marks an epoch in the history of the branch of medicine in which he has made such an indelible mark. The rule which provides for the resignation of teachers on attaining the age of sixty-five—salutary enough under ordinary circumstances to make one wish that even less latitude were allowed—occasionally strikes one as harsh and oppressive. In spite of the tendency to physical degeneration which pessimists recognize as the product of an advanced civilization, Sir Joseph Lister still appears as active and as able as when his fertile discovery opened

up fresh horizons in surgery and gave the British School of Surgery an *éclat* which it has since fully maintained. Sir Joseph retains by special grace, his post as surgeon to the hospital for another year.—*Med. Press.*

FOLK MEDICINE IN RUSSIA.

Slovo, of Kiév, reports some curious instances of popular doctoring in South Russia. The rural dentist places his patient upon a little stool and examines him. If an upper tooth is to be pulled he preforms the operation with a simple pair of tongs like that used by cobblers. But if a lower tooth is to be extracted the operation is more complicated. The tooth is tied very skilfully with a violin string. The other end of the string is fastened to a hook in the ceiling. Then the stool is removed with a jerk from beneath the patient, who falls, his tooth remaining on the string, sometimes with the flesh around it. Intermittent fever is cured either by live frogs or by fright. When the sickness breaks out the patient is made to carry about him as many live frogs as can be put in his clothes. If that treatment does not help the patient his fellow-villagers try to frighten him. The most popular method of doing that is known by the name of Likaniye. A crowd of men and women come into the house and raise a quarrel with the patient. They treat him to the loudest and most offensive terms of reproach. That naturally irritates him, and he answers in similar terms. The crowd takes offence at his rude expressions and resolves to lynch him. A rope is put around his neck and he is dragged about until insensible on account of fright.—*The Sun.*

PROFESSOR VIRCHOW ON SICK NURSING.

Where the State controls and subsidizes hospitals, many difficulties occur from which our voluntary system happily exempts us. Among these is what is called "the religious question in nursing." Occasional differences have arisen from time to time in one or other of our hospital establishments, but the strength of the voluntary system is that it admits of great variety and individual adjustment; so that each form of opinion finds the opportunity of development and representation at one place or other, and in its own appropriate form. In Paris the forcible intervention of the municipality has been a great source of heart-burning and dispute, which is not yet allayed, the religious sisterhoods having been evicted from most of the hospitals. In Berlin the same conflict is arising, and in the course of a recent debate in the Berlin Municipal Council, Professor Virchow is reported to have said: "Everybody knows how the struggle between creeds and creedlessness has developed in our days, and how it is constantly becoming keener. Everybody knows that creeds claim supremacy in the tending of the sick, but we are profoundly interested in keeping away this conflict from the sick bed and in permitting the spirit of humanity alone to assert itself there. It is not easy effectually to accomplish this, but the community can and ought to interfere positively in this matter, for it establishes numerous hospitals, and thus has an opportunity of providing for the training of sick nurses without regard to creed. No patient is asked of what religion he is, but is only examined to ascertain whether he is ill and needs to be received into such an institution. Similarly, the sick nurses, who self-sacrificingly devote their services to the sick, ought to be shielded from all religious controversy. We must also not overlook the private tending of the sick in the city, and by means of our schools for sick nurses in the hospitals we ought to provide persons who will protect the patients from the intrusion of religious arrogance. I remark, however, that I am far from accusing religious attendants on the sick of inhumanity or deficient sense of duty." This naturally gives great umbrage to the orthodox and Ultramontane journals, who discuss this utterance with bitter indignation, and complain that while spoken in the name of freedom, it savours of intolerance.—*Brit. Med. Jour.*

NEW METHOD OF EXAMINING SPECIMENS OF BLOOD.

A method of making permanent preparations of blood has recently been described by Dr. R. Muir in the *Journal of Anatomy*, which promises to be of great

use in clinical investigation. The specimens thus prepared can be preserved indefinitely, and compared with others obtained from the same patient at subsequent periods. The method is quite simple. The films are prepared on cover-glasses in the usual way, and, before they have time to dry, are placed in a saturated aqueous solution of corrosive sublimate (to which a little common salt may be added) for half an hour. The corrosive sublimate is then washed away with a three-quarter per cent. solution of common salt, and the film is further hardened by a few minutes' immersion in methylated spirit and then absolute alcohol. The specimen can then be stained by the ordinary reagents, very good results being given by double staining with eosine and hæmatoxyline, the red corpuscles being stained by the eosine, while the nuclei of the leucocytes are prominently revealed by the hæmatoxyline.—*Lancet.*

TRAINING BY HYPNOTISM.

The present system of keeping criminals in prison in order to ensure a brief respite from their evil practices is obviously open to criticism from a moral as well as from a prophylactic point of view. The delinquent leaves durance vile a sadder, but not by any means a wiser, man. Hence any method of "suggesting" the propriety of reform becomes a matter of interest. Dr. Bérillon, of Paris, claims to have had great success in the treatment of various bad habits in children by hypnotic suggestion. He finds that eight out of ten healthy children are readily amenable to hypnotic influence, and can thus be effectually weaned from their evil practices, whether these be of a minor and physical form, such as nail-biting, or stammering, or a more serious form, such as a preference for untruthfulness, kleptomania, mere laziness, or cowardice or moral perversity. The next step will doubtless be to galvanize lads afflicted with a chronic indispositon to exertion into a commendable love for study. In the meantime, Dr. Bérillon should be invited to "try his hand" on kleptomaniacs and perverters of the truth who have long since left school. In spite of the fact that the merit of good conduct is minimized by the reform being made compulsory, it would be a boon if, instead of sending kleptomaniac ladies of birth and education to prison, the magistrate were empowered to order them to undergo a hypnotic *séance*, the hypnotizer being required to go bail for their future good conduct. Other things being equal, hypnotism might be preferable to circumcision as a cure for onanism or genito-urinary incontinence, while as a remedy for stuttering, it would have the merit of restoring speech without the tedious course of training which Mr. Behnke and his congeners have found necessary. One is disposed to take a less pessimistic view of life in view of the possibility of hypnotizing children out of the habit of throwing stones at trains, of rendering them truthful, industrious and cleanly, and of desisting from the habit of worrying adults of peaceful proclivities. If Dr. Bérillon can effect this, or even a small proportion of it, he will have earned the gratitude of future generations.—*Med. Press.*

THE EVILS OF MEDICAL EXPERT TESTIMONY.

In a paper published in the July number of the *New York Medical Examiner*, Dr. B. Sachs has called attention to some of the evils attending the methods of eliciting medical expert testimony in our courts at the present day. The principal evils are that the experts are called by the parties to an action instead of by the court itself; that the medical testimony is elicited on verbal examination and cross-examination in court; that the object of such cross-examination is not so much to prove that the data upon which a judgment was founded are wrong as that the person who has passed this judgment has improper motives for appearing in the case or is ignorant of, or has possibly forgotten, some facts, of minute anatomy, that are entirely irrelevant to the case. The author suggests that a law be enacted that will reform the present condition of affairs, and that the expert should be called by the Court, so as to secure impartial testimony and unbiased judgment. —*N. CH. MARCHAND'S

PEROXIDE OF HYDROGEN.

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

THE MOST POWERFUL BACTERICIDE AND PUS DESTROYER.
ENDORSED BY THE MEDICAL PROFESSION.
UNIFORM IN STRENGTH, PURITY, STABILITY.
RETAINS GERMICIDAL POWER FOR ANY LENGTH OF TIME.
TAKEN INTERNALLY OR APPLIED EXTERNALLY WITH PERFECT SAFETY.

Send for free book of 72 pages giving articles by the following contributors:

DR. JOHN AULDE, of Philadelphia, Pa. "Hydrogen Peroxide—Résumé." *New York Medical Journal.*

DR. E. CHAREST, of St. Cloud, Minn. "Peroxide of Hydrogen for Gonorrhœa." *Medical World* of Philadelphia, Pa.

NOTE.—Avoid substitutes—in shape of the commercial article bottled—unfit and unsafe to use as a medicine.

Ch. Marchand's Peroxide of Hydrogen (Medicinal) sold only in 4-oz., 8-oz., and 16-oz. bottles, bearing a blue label, white letters, red and gold border, with his signature. Never sold in bulk.

PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.

PREPARED ONLY BY

SOLD BY LEADING DRUGGISTS.

Laboratory, 28 Prince Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{75}$ gr.), Atropiæ Sulph. ($\frac{1}{100}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{75}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

REMARKS ON HAFFKINE'S METHOD OF PROTECTIVE INOCULATION AGAINST CHOLERA.

By E. H. HANKIN,

FELLOW OF ST. JOHN'S COLLEGE, CAMBRIDGE; CHEMICAL EXAMINER, ANALYST AND BACTERIOLOGIST TO THE NORTH-WEST PROVINCES, INDIA.

As I have recently been subjected by M. Haffkine to his anti-cholera inoculations, I propose to give an account of my experiences and a description of the method employed in the production of the vaccine.

In the course of his researches on the cholera vibrio which have been carried on during the last two years, M. Haffkine has met with many facts which tend to remove the difficulties that have hitherto stood in the way of accepting this microbe as the cause of cholera. Among these difficulties may be mentioned the impossibility of reproducing a disease in any way resembling human cholera by injections of Koch's vibrio into animals. M. Haffkine has recently succeeded in doing this in rabbits by a very simple and ingenious method. It is well known that the blood serum of the rabbit has the power of killing the cholera microbe. By cultivating the vibrio, first in diluted and then in undiluted rabbit's serum, M. Haffkine has succeeded in "acclimatising" it, so that at length it is completely unharmed by the bactericidal action in question. If a small quantity of a culture in rabbit's serum of these acclimatised vibrios be injected into the veins of the rabbit, the animal will succumb, showing symptoms which M. Haffkine assures me are extremely similar to those of typical cholera. During the collapsed condition that precedes death, cramps are frequently observed, and on *post-mortem* examination the intestine is found to be filled with the typical "rice-water" secretion. The latter, and also the mucous membrane of the intestine, contain the vibrios in large numbers. In some cases they have been found in the bile duct and ureter, but never in any other part of the body. Generally these symptoms appeared within a few days of inoculation, but more rarely the animal remained in apparently good health for periods extending to a couple of months before the symptoms developed. These latter experiments suggest an explanation of those anomalous cases in which a patient has been observed to succumb to a second attack of cholera during the same epidemic. Perhaps he had never been really free from the virus after his first attack. The cholera may have existed in a latent condition, as was the case with these rabbits. I owe my best thanks to M. Haffkine for his permission to mention these results. It is to be hoped that he will soon publish an account of them in detail.

In this, as in many other cases, the first step towards obtaining a protective vaccine was the preparation of an abnormally virulent form of the microbe, the so-called *virus fixe* or *virus exaltè*. M. Haffkine succeeded in this by passing the microbe through a series of guinea-pigs. If a guinea-pig is inoculated into the peritoneum with a suspension of an agar culture of the microbe, it will succumb, and in the peritoneum is found an exudation containing a larger or smaller number of the vibrios. If this exudation is injected into the peritoneum of a second guinea-pig, the latter will also succumb, and so on with a third; but, unless certain precautions are taken, the series cannot be kept up. Each successive exudation will be found to contain fewer and fewer microbes,

and at last the total number of microbes present will not be sufficient to kill the next guinea-pig in the series. To avoid this result a procedure has been adopted based on the following facts: The quantity of exudation formed varies in different cases. Usually, if a large guinea-pig is employed, a copious exudation, containing relatively few microbes, is produced. A small guinea-pig, on the other hand, yields a small quantity of exudation rich in microbes. Apparently the quantity of the exudation is a measure of the power of resistance possessed by the individual. M. Haffkine has based, on these facts, his method of passing the microbe through a series of animals. A guinea-pig is inoculated into the peritoneal cavity with cholera vibrios from an agar culture. On its death the peritoneal exudation is removed with a pipette, placed in a test tube, and left for several hours at the temperature of the room. If it is abundant (several cubic centimetres), it is then injected into the peritoneum of a small guinea-pig. If, on the other hand, it is small in quantity (1 cubic centimetre or less), it is injected into a fully-grown animal. On the death of the animals in the former case, the liquid injected will be found to have become concentrated; in the latter case, an increase in quantity will be observed. By attending to these precautions, the cholera virus can be passed through an indefinitely long series of animals. From each exudation in a series, an agar culture is made for the purpose of controlling the purity. Each successive culture will be found to be more virulent than its predecessors; also the guinea-pigs in the series die in shorter and shorter times after injection of the exudation. Between the twentieth and thirtieth passage the maximum degree of virulence appears to be reached. At this stage the peritoneal exudation is fatal to guinea-pigs in six to eight hours after its injection into the peritoneum. Agar cultures made from such an exudation also possess and retain this increased degree of virulence. Microbes from these cultures can kill rabbits and pigeons in doses which would be perfectly harmless if given in cultures of the ordinary degree of virulence. In fact, this *virus exalté* appears to be about twenty times as virulent as the ordinary form of the microbe.

As above stated, this *virus exalté* is rapidly fatal to guinea-pigs when injected into the peritoneum. It also kills them with certainty when introduced into the intestine or when given *per os* after neutralization of the gastric juice with soda and quieting the intestines with opium according to Koch's method. It also differs from the ordinary form of the microbe in that it kills guinea-pigs when injected in small doses into the depth of the muscular tissue of the thigh.

If, however, it is injected under the skin, the *virus exaltè* does not kill the animal; it produces a purely local malady. After a few hours an extensive œdema develops. In a few days the necrosed mass of tissue drops off, leaving a granulating wound. This at length heals completely. The animal is now found to be immune against inoculation with cholera in any way whatever, whether it is tested with ordinary or with strengthened virus, and whether it is introduced into the peritoneum, the intestine, or the muscular tissue. Obviously, however, such a method of inoculation could not be practically employed. It is necessary to devise some method of first protecting the guinea-pig against the necrosis produced by the *virus exalté*. This can be accomplished readily by a previous treatment with attenuated virus.

The attenuated virus is prepared by growing the microbe in a slow current of air. About 10 cubic centimetres of bouillon is placed in a flask having two lateral tubulures, and inoculated with the strengthened virus. The flask is placed in an incubator at a temperature of 39° C., and by means of a tube connected with one of the tubulures at one end, and, passing outside the incubator to a water-pump at the other, a slow current of air continually passes over the surface of the bouillon. The other tubulure of the flask is connected with a wash-bottle containing water and placed in the incubator, in order to saturate the entering air with aqueous vapor. This precaution is necessary to prevent undue evaporation, as the bouillon only forms a shallow layer at the bottom of the flask. Under these conditions the microbes produce a culture, but then rapidly die. It is therefore necessary to reinoculate them every third day into a fresh flask of bouillon. After each passage the microbes are found to be more and more attenuated. At last, after a series of passages under these

conditions, the microbes are found to be so altered that they have completely lost the power of producing necrosis in guinea-pigs even when injected under the skin in exaggerated doses. They however, retain the power of still killing these animals when injected into the peritoneum in quantities only slightly larger than is necessary to attain this result with the ordinary virus.

If a dose of this attenuated virus, (say one-eighth of a twenty-four hour old agar culture) is injected under the skin of a guinea-pig an extensive œdema develops within twenty-four hours. During the next few days this diminishes in size, leaving, however, a hard nodule, which persists for a considerable time. If a week later the animal is inoculated with a similar quantity of the strengthened virus an œdema develops, which is less than in the first case and does not lead to necrosis. When tested a few days later the animal is found to have acquired an immunity against the cholera microbe in whatever way it may be inoculated. This immunity has been found to be undiminished a couple of months after treatment.

Rabbits have also been made immune by the same method. They then show themselves refractory to every form of inoculation, including the method above described, which in the control animals leads to a disease resembling the cholera of human beings. M. Haffkine has also produced this immunity in pigeons. These facts led M. Haffkine to try the effect of these inoculations on himself, and afterwards on seven other gentlemen. The following is the account of my own case:

August 16th, midday, Dr. Roux inoculated me with one-eighth of a 24-hour old agar culture of the attenuated virus suspended in 1 cubic centimetre of bouillon in my left side, about 2 inches above the crest of the ilium. 1 P. M. Slight pain locally. 4 P. M. Swelling noticeable, and pain on movement. 8 P. M. Owing to pain on moving found walking about difficult. 10 P. M. Temperature began to rise; noticed a feeling of *malaise*. 12 midnight. Noticed temperature of 100°. This was the highest point reached.

August 17th. 7 A. M. Woke up; felt better; temperature normal. The swelling formed an area about 9 inches long and 2 or 3 wide, extending towards the inguinal lymphatic glands; painful on pressure, and reddened. 12 midday. During the day I worked as usual in the Institut Pasteur, but had a bad appetite and a feeling of fatigue, which once or twice impelled me to lie down for a short time. 3 P. M. The swelling extended during the day to the crest of the pubes and to within an inch of the umbilicus. This secondary extension of the swollen area was not painful on pressure, or reddened. 7 P. M. Felt bilious. 9 P. M. Took four capsules of castor oil.

August 18th. Woke up, feeling all right after a sound sleep; pain notably diminished; could walk about with ease, and went to a swimming bath.

August 19th. Swelling and redness of skin greatly decreased; pain on pressure trivial.

August 21st. 6 P. M. Inoculation with one-eighth of an agar culture of *virus exaltè* suspended in bouillon. The injection was made on the center of the inner side of the left arm. 11 P. M. Painful area extended to axilla; slight and occasional headache.

August 22. 4 P. M. Woke up; found it difficult to get out of bed owing to pain, but in a few minutes became accustomed to change of position, and walked about with ease; a slight *malaise* and fever. 6. A. M. Felt better. 9 A. M. Breakfast, good appetite. During the day, August 22nd, slept most of the time, but was awakened every hour to take my temperature; in the evening felt bilious and constipated; took about ½ ounce of liquorice powder; the swelling now extended from the axilla nearly to the elbow; this area was very sharply defined by the redness of the skin. Slept well all night.

August 23rd. Woke up feeling quite well. Pain had decreased, but the swollen area had extended, reaching about 3 inches below elbow. This secondary extension of the swollen area was not painful on pressure, and the skin had a normal color.

August 24th. Pain and swelling notably decreased. Skin beginning to assume a yellow hue.

August 25th. Further decrease of swelling. For an area measuring about 5 inches by 3, the skin was colored yellow.

No enlarged glands were noticed all through the experiment. At present the only trace of the inoculation is a small hard nodule, less than half an inch in diameter, at each seat of injection.

With regard to these inoculations I should like to point out that although the œdematous swelling develops with startling rapidity, there is no reason for considering it as likely to lead to any dangerous inflammation. The cholera microbe is not one that is capable of producing pus. Knowing this fact, neither M. Haffkine or I made any attempt to keep quiet or rest ourselves after our inoculation. M. Haffkine happened to be busy after his first inoculation, and in spite of his fever worked for twenty-four hours continuously in the laboratory without food. Two hours after my second inoculation I experienced the first part of my fever. It is noteworthy that both M. Haffkine and I had more fever after the second inoculation than after the first. All the other gentlemen who have been inoculated experienced only a trivial elevation of temperature and

of discomfort after their second inoculation. Probably this is due to the fact that M. Haffkine and I had our second doses at comparatively short intervals after the first (five and six days respectively), and, as experiments on guinea-pigs indicate, these intervals were too short for the immunifying effect of the first dose to have completely developed.

The seven other cases presented symptoms essentially similar to my own, only, as above mentioned, the second inoculation (which was made after seven or eight days) produced far less general and local disturbance than the first. In two or three cases a transient constipation has been observed to follow the inoculation. In one case diarrhœa had been present for some days before the first inoculation, and vanished the day after it was performed.

M. Haffkine finds that it is also possible to vaccinate guinea-pigs by means of cultures previously sterilized by heat. In these cases the local reaction appears to be less than occurs after inoculation with living cultures. The immunity produced, however, does not seem to be of such a permanent character as that produced by the living microbe. It is possible, nevertheless, that for inoculations on human beings it may be well to commence with sterilized cultures, in order to diminish, as far as possible, the discomfort produced by later inoculations with the living virus.

I may mention here that in all his experiments M. Haffkine employs cultures on agar in preference to those in bouillon. The latter contain far more soluble poisons than the former, and there is reason for thinking that, as with the allied microbe the vibrio Metschnikovi, it is the less readily soluble substances contained in the bodies of the microbes that are concerned in the production of immunity.

What proof have we that these inoculations are of any value whatever in protecting human beings against cholera? If the cholera vibrio is really the cause of this disease, the conditions of infection that obtain in Nature and in the laboratory must be widely different. How, then, can success in producing immunity against "laboratory infection" of a guinea-pig justify us in concluding that we have obtained immunity against "natural infection" of a human being? Obviously we have no direct and absolute demonstration of the value of these inoculations, and no doubt those people who need such proof before they are convinced will feel themselves justified in being "dead certain" of the futility of M. Haffkine's method for a considerable time to come.

In the first place it may be noted that the fact that there is a difference—it may be a great difference—between artificial and natural infection, though suggesting a source of error, is not of itself a reason for thinking that immunity against the one is not immunity against the other. In discussing the probability of an animal or a human being being immune against a particular microbe, we are concerned not so much with how the microbe can get into the system, but with what it does or does not do when it gets there. If any animal has been made immune against the cholera microbe, it has always been found to be capable of resisting it, in whatever way it may have been introduced into the body. Consequently, if a human being has been made immune against the offects of the cholera microbe when injected under the skin, analogy suggests that he is immune against the same microbe when it seeks to enter the system by the natural way, whatever that may be. But are those gentlemen who have been inoculated by M. Haffkine immune to the effects of the cholera microbe when inoculated under the skin? This is a matter which can be put to the test with great facility. The effects of a subcutaneous inoculation of the attenuated cholera microbe on a human being may be said now to be well known and easily recognised. There is a widespread and rapidly developing œdematous swelling and redness, which only vanish gradually after the lapse of several days. A small hard nodule also appears at the seat of inoculation. These changes may be regarded as a distinct character of the cholera inoculation. The fever and *malaise*, on the other hand, can not be so regarded; probably a similar injection of almost any microbe would produce a similar elevation of temperature.

Consequently, the presence or absence of a "local immunity" in a human being who has been subjected to M. Haffkine's treatment can be readily tested by a repetition of his first injection, namely, that of the attenuated virus. M. Haffkine has conceived the good idea of performing this experiment five weeks after his inoculation with the strengthened virus. After

the injection a swelling rapidly developed, and as rapidly disappeared. It had almost gone in twenty-four hours, leaving no hard nodule, as had been the case with the previous inoculations. The result is sufficiently striking when it is remembered that the œdema produced by the first inoculation in M. Haffkine's case took nine days to disappear. As might have been expected, a passing rise of temperature was produced, but this also took place in a guinea-pig that had received the same repeated inoculation, and that had previously been proved to be perfectly immune against cholera on several occasions.

Another objection suggests itself. Dr. Cunningham has isolated several distinct and permanent varieties (or as he prefers to call them, species) of the cholera microbe. Will immunity against one of them confer immunity against another? M. Haffkine's vaccines have been prepared from a cholera microbe of Indian origin, and his inoculated guinea-pigs have shown themselves to be immune against this race. Considering the number of different varieties—a dozen or more—that Dr. Cunningham has described, it is, to say the least, improbable that a chlorea microbe isolated two months ago from a case in the Necker Hospital in Paris should be of identically the same race as the one of Indian origin that has been so long in use in the Pasteur Institute. M. Haffkine finds that a guinea-pig that has been prepared by his method is just as refractory to one microbe as to the other.

Is this method of inoculation likely to confer a permanent immunity? To this question no definite answer can be given as yet. Guinea-pigs inoculated by the same method as has been employed for human beings have been found after two months to have lost none of their immunity. *A priori,* it is far more probable that an inoculation with *virus exalté* should confer a lasting immunity than a slight attack of cholera. In human beings the immunity can always be tested from time to time by a subcutaneous inoculation. In the event of a lasting œdema being produced by this test inoculation, it can form the starting point for a repeated treatment. It may be noted that there is no reason for thinking that this method of inoculation could be any sourse of danger to other individuals. There is, on the other hand, every reason for believing that the microbes injected are rapidly destroyed in the body, most probably *in situ.*

Lastly, it is important to remember that very probably after the first inoculation, less probably after the second, there may be a temporary diminution in the power of resisting the entry of the cholera microbes. Most probably within three or four days of the injection the power of resisting the attack of the cholera microbes has returned to normal, and after that time will continue to increase. If this is so, these inoculations should not be practised in a given place at the time that an epidemic is raging, without great caution. Before forming a definite conclusion with regard to this, further experiments on animals are needed.

The evidence at present existing shows that M. Haffkine's method of inoculation is not attended by any grave disturbance of health, and that it can be practised on human beings with perfect safety. The fact that it produces immunity against cholera in any form, in animals of such widely different organization as guinea-pigs and pigeons, gives reason for hoping that it may produce an equally good effect in human beings, but it must necessarily be a long time before we can possess any evidence of any value on this point.—*Brit. Med. Jour.*

SALOPHEN.

Siebel (*Therap. Monatshefte,* January, 1892) says that salol was introduced on account of some of the unpleasant symptoms produced by the salicylates. Salol, however, has not been found harmless, and is contraindicated in cases of renal disease. Salophen is a combination of salicylic acid with acetylparamidophenolether.

It is split up into these two constituents by pancreatic ferment, but not by the acid gastric juice. Any of the drug not so decomposed has been found to be excreted with the fæces. Salophen hinders decomposition when in such quantity as to provide sufficient salicylic acid. It is without taste or smell, and has very feeble toxic properties. At most, symptoms of salicylic acid intoxication would be produced, for the other constituent is without poisonous qualities. Dr. Guttman has spoken favorably of the clinical properties of salophen.—*Brit. Med. Jour.*

Communications.

WHEN SHALL WE TREPHINE IN FRACTURES OF THE SKULL?*

By EMORY LANPHEAR, M. D., PH. D.,
KANSAS CITY, MO.

SURGEON TO EAST SIDE DISPENSARY; PROFESSOR OF ORTHOPÆDIC SURGERY IN THE UNIVERSITY MEDICAL COLLEGE.

Not so very long ago (a dozen years) the only indications supposed to demand operation, in fractures of the skull, were embraced in these rules:

1. In *compound*, *comminuted* fractures, *with or without brain symptoms*, the depressed bone should be elevated and the fragments removed to be rid of the irritation the spiculæ will produce and to avoid the inflammation of the brain and its membranes such irritation would be likely to set up

2. In all cases of *local* injury to the skull whether fracture or bruise, followed by a clear evidence of inflammation of bone and persistent symptoms of brain irritation, or of pus between the bone and dura mater, the trephine should be resorted to.

3. Punctured fractures almost invariably lead to inflammation of brain, sooner or later—are the most dangerous of all fractures—and require the use of the trephine *with or without* the presence of brain symptoms.

Upon the contrary it was thought: "Never operate unless the symptoms *are urgent*" (with the above exceptions); in diffused injuries to the cranium and its contents, "operative procedures are *never* justifiable, since the injury is not limited to one point and cannot be relieved by an operation;" and finally "in compound fractures, *even with depression* if not comminuted, an operation should be performed unless the symptoms of compression from local pressure are great;" trephining in gun-shot fractures was almost unknown. Such were the directions of one of our best teachers in 1880.

Now we know that we should operate *in every case* of fracture with depression, even if there be no symptoms whatever; in many diffused injuries trephining is indicated; gun-shot wounds of the skull should invariably be followed by operation, and some go so far as to say that even simple fissure ought to be treated by trephining. Thus the late Dr. D. Hayes Agnew (*University Medical Magazine*, October 1891) in discussing the subject of traumatic epilepsy says: "It is not saying too much to assume that surgery is responsible for the great majority of traumatic epilepsies. The old members of our profession cannot, of course, be held responsible for not practising those methods which time, observation, vivisection and knowledge derived from collateral branches of study have made possible. They said that human life is too precious a thing to be jeopardized by overstepping the bounds of a wise conservatism. On the other hand no charity can release him from responsibility, who, from being wedded to old traditions and who can discover nothing valuable outside of his own narrow horizon, declines to keep step in the grand procession. The doctrine that depressed fractures of the skull without symptoms require no operative interference, a doctrine which in the past has been so deeply rooted in the professional mind, I hold to be responsible for very many of the unfortunate sequels of head injuries. However small may be the depression which follows a fracture of the cranium, save in one or two localities, it will encroach enough upon the dural nerves to cause more or less irritation, which, though insignificant at first and not at all recognizable to the consciousness of the patient, yet eventually will be propagated to the cortex and brain ganglia until finally the paroxysmal explosion occurs. * * * Whenever, therefore, in my judgment, the profession can accept the doctrine that *all depressed fractures of the cranium, however slight may be the depression, and entirely irrespective of pressure symptoms are proper subjects for trephining,* then will traumatic epilepsy largely disappear; indeed, I am sure that he who shall propose to tabulate at the end of the next twenty-five years the cases of epilepsy will find, as compared with the present time, a meagre supply for his purpose. It is not improbable indeed, in view of the greatly diminished risk from trephining, *that the operation will be extended even to cases of simple fracture or fissure of the skull.*"

The reason assigned by Dr, Agnew is that no surgeon, however skilled, can

*Read before the Jackson County Medical Society.

determine, without operation, what has happened inside the skull, even in a simple fracture; therefore the necessity for inspection of the interior as well as exterior surface; which is in conformity with the statement of Bouillaud that no blow upon the head, however insignificant it may appear to be, is too slight to excite anxiety regarding the future. For the sequel may be long delayed; as says Dr. Allen McLane Hamilton (*Pepper's System of Medicine*, Vol. v. p, 471): "It is quite common to find old fractures, with depressions which have existed for years without any seeming bad effects, suddenly lighting up convulsions under the influence of some new excitement." Nor, as Agnew says, must there be anything more than a simple fracture to produce disastrous results years after the reception of the injury; for these apparently simple fissures may be attended by grave intra-cranial conditions. No man can say that a fracture of the skull, however simple it may appear, will not be followed by meningeal hæmorrhage, or later by epilepsy, insanity, etc. A case which I saw some years ago in consultation with Dr. L. A Berger, of this city forcibly illustrates this point:

Case 1.—C. L.———, of German birth, age fifty-three, a furrier, of powerful build; was quiet, reserved, and modest in demeanor; not a drinking man; family history good. During the Franco-Prussian war (about 1870) he was struck with the butt of a musket (shown by scar over right parietal eminence and anteriorly). There was no apparent injury to skull, no fracture according to history of case, though he was unconscious for two or three days after time of injury; he went again into active service three weeks after receiving the blow. From 1871 to 1881, (when he came to America and married) his history is a blank. Since his marriage he had developed a peculiar condition; he is subject to attacks of vertigo, is seized with most violent fits of anger (from most trivial causes), often lasting two hours and terminating in an melancholic state continuing a day or two. During his last year of life he has been alternately morose, secretive, melancholic and negligent in his business, and extremely restless. On October 18, (1886) he became unusually restless; ran out of house and remained in country all day, walking; returned in evening completely exhausted and unable to account for his disappearance or whereabouts. October 20, no particular change except tendency to talk incessantly; pupils normal; no deviation on protrusion of tongue; no tremor or paralysis; physical functions unimpaired; temperature normal; sleep little and disturbed. He was given bromides and tonics. During next thirty days there was no perceptible change except that gradually a condition like dementia supervened. November 22, he became suddenly unconscious, stertorous breathing, pupils dilated, inability to swallow, pulse 120, temperature 100°. During day breathing assumed Cheyne-Stokes character and death occured twelve hours after onset of coma. *Autopsy.*—Post-mortem examination was made eighteen hours after death; present Drs. Berger, Eggers, Adams and Lanphear. Calvaria removed with difficulty, dura mater adherent; cloudy exudate beneath dura, at site of injury; also in pia. Dura thickened, opaque and inseparable from arachnoid from point of injury up to longitudinal sinus; here was a small piece of bone driven across longitudinal fissure and penetrating the falx cerebri; size of fragment, one inch long and one-sixth inch wide; no effusion or hæmorrhage in brain or ventricles; no other lesions discoverable upon most careful examination.

Here was a case of injury to the skull, with no fracture discoverable at time of accident; yet insanity resulted two years later and death from pachymeningitis sixteen years afterward. It is not improbable that if trephining had been done at time of injury no subsequent trouble would have occurred. The history of this case emphasizes the point I shall presently make, that all cases of local injury to the skull, accompanied by unconsciousness of more than an hour's duration should be trephined.

Another case in which there was no evidence of fracture at time of reception of injury—save prolonged unconsciousness—yet one in which trephining would probably have prevented development of mental trouble, was the following (noticed in the *Kansas City Medical Index*, August 1888):

Case II.—Isaac F———, age forty-one, laborer, family history unknown, previous health excellent, was in September 1887, struck upon the head by falling timbers. The external injury was not great, but he

was comatose for a time, and the attending surgeon, Dr. N. J. Pettijohn, of Kansas City, desired to trephine near the site of the injury; the consulting surgeons, however, demurred because the symptoms present were not of an alarming character, and he showed evidence of rallying. He eventually recovered consciousness, and was restored to fair physical health; but his mental condition is one of serious aspect. He was for some weeks recently under my care, with the object of determining, if possible, the justifiability of trephining now, and the point of selection for operation. I was unable to decide that there is *now* any local point of excitation (the only peripheral symptoms being a tingling and numbness of one little finger)—in other words, there seems to be evidence of general periencephalitis (chronic), and as there was absolutely no improvement under proper treatment, I had him committed to the state lunatic asylum, where he will probably pass the remainder of his days.

Such cases as these are not rare and they are not without their lesson. They teach that in *all cases* where there is even a *suspicion* that there is depression of the internal table the trephine should be employed, notwithstanding the old rule we have been wont to follow. I have used the word "suspicion" advisedly; we cannot, in many instances, be certain that there is a fracture until we cut down to see. As Moulin (*Practice of Surgery*, page 601) says: "Contusions, fissures and fractures do not always admit of proof; and even when the bone is comminuted and the depression considerable, the diagnosis is often a conjecture, owing to the amount of blood extravasated. The gravity of simple fractures arises from the fact that serious injury to important structures is so often associated with them. That I am correct in my assertion that we are justified in trephining even upon a *suspicion* of fracture is proven by the following case:

Case III.—Tod K——, age thirteen years, fell from the bluff, a distance of 65 feet, striking upon his head. The accident occurred about 11 a. m. May 16, 1891. He was not unconscious when conveyed to his home and a physician pronounced his wound not a serious one, washed the lacerated scalp and applied an antiseptic dressing. At 1 p. m. the boy became somewhat drowsy and vomited repeatedly, at which time I was called to take charge of the case. He was quite stupid, pulse very weak, skin of a purple color, "shock" pronounced. Examination showed a cut in scalp about two inches long on the left median line, just behind the parietal eminence; but no special indication of fracture. At 3 p. m., assisted by Dr. John Wilson, I shaved the scalp and enlarged the skin-cut, under chloroform anæsthesia. When the scalp was turned back an extensive fracture of the parietal bone was revealed, with depression two inches or more across. This fracture had been hidden by the scalp's slipping over it entirely and by the boggy swelling of the injured soft parts. A small opening was chiseled in the external plate and an elevator introduced; but the depressed bone could not be raised thus, so a ¾ inch trephine was applied. On removal of the button a very considerable amount of blood came from between the bone and the dura. A large spicula of the vitreous plate projected through the dura and into the brain tissue; this was removed, together with a number of fragments. There was considerable bulging of the brain through the opening and the protruded matter was pulseless. Upon raising the depressed bone into proper position the brain sank and soon pulsation returned and simultaneously the purple hue of the skin gradually disappeared. All clots and fragments having been removed the wound was irrigated with hot water (previously boiled), the wound in the dura closed by a fine catgut suture, a strip of bi-chloride gauze placed next to the dura and projecting through scalp-wound for drainage and the cut in scalp sewed with catgut. The usual dressings were applied and patient put to bed in good condition, color and pulse greatly improved.

At 10-30 p. m. temperature normal, no pain, patient bright and cheerful and talking as if nothing had occurred. Morphine, gr. ⅛, *per orem*, if needed for sleep, was ordered.

May 17th. At 3 p. m. in fine shape—pulse 90, temperature 99.° No pain; free motion in all extremities.

May 18th. Sat up while drainage was removed and dressings applied; no fever; no pain; wound in fine shape, no pus, healing nicely begun. Dressed with iodoform, bi-chloride gauze, cotton and bandage.

May 19th. Condition excellent—no pain; no fever; eats and sleeps well.

May 26th. Dressed head; wound practically well.

May 31st. Patient running about over house. Wound entirely healed. Discharged well.

What the result would have been in this case if the so-called "conservative treatment" of the first doctor had been continued can, of course, be only a matter of conjecture. But I feel sure that if death had not occurred within a day or two, an inflammatory process would have occurred which would have necessitated operation a week or two later when there would have been far more danger; or, if this had fortunately been escaped, an epilepsy would probably have arisen in later years. The objection of Brodie which strange to say, is supported by Ashhurst, (*Principles and Practice of Surgery*, 1889, page 339) that it is better to leave imbedded in the brain, a foreign body or fragment of bone rather than use any force in its removal, is one that can not be too strongly condemned. If the surgeon be *absolutely clean*—i. e., surgically clean—he is not going to do much mischief provided he is reasonably careful. Ashhurst's assertion that meningitis and encephalitis are likely to occur from surgical handling is as utterly false as many other fallacies of ancient pathology; an experience in a large number of cases of operative brain surgery has lead me to know that inflammation is an accident due to infection prior to operation, or to carelessness on the part of the surgeon. A clean wound of the brain or of the meninges will heal without the least sign of inflammation, just as will one in the broad ligament and abdominal walls. Inflammation is not necessary to healing and should not be found in any wound made by a surgeon. As Senn says (*Principles of Surgery*, page 1): "Studied from a surgical standpoint, regeneration includes the process observed in the healing of wounds and the complete or partial restoration of parts damaged. * * * Regeneration and inflammation are distinct conditions, which should no longer be confounded or considered from the same etiological and pathological standpoint. An ideal regeneration takes place without inflammation provided the seat of injury or tissue destruction remains aseptic; that is, free from pathogenic organisms."

We being, then, able to open up the scalp freely, or the skull also, without additional danger, I am not sure but Agnew is correct in asserting that we would be justified in operating in even simple fissure; we certainly ought to do so in every suspicious case. On the other hand, no case, unless the patient is seen to be dying, should be considered too grave for operation. An illustrative case is this:

Case IV.—George E.——, aged twenty-four, was struck by a locomotive on the morning of April 2, 1891. During the day he was seen by at least three prominent surgeons who said that recovery was impossible and all refused to risk an operation. I saw him in consultation with Dr. W. S. Allen, at 6 p. m. At that time he was partially conscious and begged me to do something to give him even a slight chance of recovery. His appearance was frightful; the whole scalp and periosteum was torn away, i. e., the scalp at the margin of the hair was broken loose and hung by a piece not more than three inches wide at the back of the neck; the flange of the drive-wheel had struck him near the coronal suture on the right side, driving the bone down into and fearfully injuring the right frontal convolutions; a fracture extended downward into the orbit, widely gaping and blood still oozing from eye and nose. This was a "diffuse injury" to the skull in which the books direct not to operate. Nevertheless he was chloroformed by Dr. Callaghan and we removed the cinders, broken bones and clots, raised the depressed bone, pushed together the bones which were separated by the long fracture from junction of saggital and lambdoidal sutures to point of crushing, and into orbit, and put in large drainage tubes, replacing scalp and holding it in place by continuous catgut suture.

April 3d. Slept nicely all night; no nausea, no fever (99+), no paralysis, but considerable frontal headache.

April 5th. Drainage removed. Patient doing well.

April 17th. Patient has made an uninterrupted recovery. Discharged from hospital well, though still weak.

In view of such an ideal result can anyone say that any case is too severe to justify an attempt to save life? Yet there are surgeons of eminence who refuse to jeopardize their reputation by operating in such cases. As for me, I believe one

patient's life better than any reputation I can ever acquire as a surgeon.

To summarize the whole matter I offer the following:

RULES FOR TREPHINING IN INJURY OF THE SKULL.

1. All cases of depressed fracture, either simple or compound, require trephining and elevation, whether there be pressure symptoms or not.

2. All punctured fractures and gunshot wounds imperatively indicate the use of the trephine.

In simple fracture of the skull where any symptoms of brain trouble persist exploratory operation should be done.

4. In all cases of local injury to the skull, whether fracture or bruise, followed by evidence of inflammation of bone or persistent symptoms of brain irritation, or of pus between the bone and dura, the trephine should be resorted to.

5. In every case of localized injury to the head where unconsciousness persists for more than an hour, exploratory operation, including opening the skull if necessary, should be done.

6. The appearance of stupor some hours after a head injury indicates meningeal hæmorrhage and requires trephining at the point of injury if known, or at point indicated by cerebral localization; the middle meningeal being the usual source of trouble.

7. Even in very extensive injury to the head, operation should be made, since removal of *dèbris*, restoration of normal contour and cleaning of injured tissues can add but little to the danger and may save life.

8. In every case of doubt exploratory operation is justifiable.

9. Compound fractures, with or without apparent depression, demand enlargement of the wound and careful exploration.

COLD IN THE HEAD.

For cold in the head while in the acute congestive stage, there is no better remedy than gelsemium. One good large dose, say ten minims of the fluid extract, taken upon going to bed will effectually dispose of this troublesome and uncomfortable affection. One dose is usually sufficient.

PRURITUS ANI.

J. E. PRYOR, M. D,
OCEAN CITY, N. J.

No local affection is more annoying and troublesome to a patient than this disease, and often the physician will be put to his "wit's end" to find means of relief. This disease is characterized by an intense, itching, burning and lancinating pain, in and around the anus, the pain often coming on in paroxysms, usually being much worse at night, after the patient has retired. The affection often extends to the surrounding tissues, the germs multiplying rapidly and burrowing in different directions, irritating the sensitive nerves, causing most intense itching. In a large number of cases, we find associated with it fistula in ano—hæmorrhoids, irritable fissure and small ulcers, each adding to the misery of the patient. A patient suffering from this trouble usually exhausts all local means he knows or ever heard of. He refrains from consulting a physician as long as he can, consequently he has become nervous, emaciated, and I may say, almost skeptical, as regards getting well.

The treatment of this trouble is varied, every physician having his own formula, besides every case must be treated on its own merits from the conditions presented. That which I have found most successful in a considerable number of cases, is as follows: When patient comes to consult me, I endeavor to get his confidence and instill him with hope, the bowels are freely opened with a saline purge, or calomel, and he is directed to report for a thorough examination, when such complications as fistula, hæmorrhoids, fissure, etc., are carefully sought for. Of course when any of these are found, they each call for their respective treatment. In a simple case of pruritis ani I order an injection of a solution of the following, which I have found to be a good antiseptic and local stimulant:

℞ Listerine ..... ℥iv
Glycerine ..... ℥vi
Acid Carbol..... gttxx
Aqua..... ad ℥vi
M. Sig. ℥ss injected in rectum once daily.

It is necessary to medicate the internal sphincter and rectum in all cases of pruritis as there is more or less irritation of these parts. I also use the different ointments and antiseptic solutions, with good results in some cases and none in others.

Lately I have employed tincture of iodine. Before using, however, I direct the patient to have the bowels thoroughly moved, and an injection of warm soap and water to be taken, the external parts to be washed and dried. Then I apply the iodine thoroughly to the diseased surface, if it is too severe, a small amount of tr. opii can be added, or the parts may be covered by vaseline protected by absorbent cotton.

After having made from four to six applications, I begin to find my patient rapidly improving, or nearly recovered. I direct him to keep the parts clean, use the injection once daily, keep the bowels open, take plenty of outdoor exercise and eat good, nutritious food. Complications, if present, must be treated according to the regular surgical methods.

VINUM IPECACUANHÆ IN WEAK LABOR PAINS.

Stillmark (*St. Petersburger medicinische Wochenschrift*, No, 18, 1892,) contributes the notes of a case of uterine inertia in which the contractions was re-established by the administration of wine of ipecac. The patient was a IV-para, with a history of easy previous labors. Three weeks before the presumptive termination of her labor the membranes spontaneously ruptured and one or two weak pains were experienced. The next morning Stillmark examined her and found head presenting in second position, os admitting two or three fingers. There were no pains. The patient was placed in a bath. Nine hours later, as the pains had not yet occurred, warm vaginal douches were applied without result. During the following night patient slept. Next morning, after a bath, warm vaginal irrigations were again used, with gentle massage to the uterus. As all this failed to establish the pains, wine of ipecac was administered in a 15-drop dose. Half-an-hour afterward the patent exclaimed that her abdomen felt hard. At 1.30 P.M., 15 drops were again administered. In three-quarters of an hour, after the second dose, strong normal pains began. In the evening the pains were weaker, and about ten o'clock had almost ceased. Five drops were now given, as vomiting had occurred after the second dose. Energetic labor pains were soon established and at 12 o'clock the child was delivered. The placenta soon followed. —*University Med. Magazine.*

LACQUER POISONING AND NOTES.

By ALICE MAC LEAN ROSS, M. D.,

PHYSICIAN TO THE MICHIGAN WOMAN'S HOSPITAL, SWATOW, CHINA, FORMERLY RESIDENT PHYSICIAN IN WOMAN'S HOSPITAL, DETROIT.

The *Rhus Vernicifera* or varnish tree as it is popularly called, grows upon every hillside in this vicinity. In Japan and North China it attains the dimensions of a good sized tree reaching twenty feet or thereabouts in height, but here it is stunted and is not tapped for its sap. Its poisonous properties are well known and it is consequently shunned by both natives and foreigners, and most cases of poisoning are caused by contact with freshly varnished lacquer ware or bric-a-brac.

The juice is a resinous substance of tawny or dark brown color when fresh, turning jet black upon exposure to the light. Its characteristic properties are imparted to it by urushic acid, an irritant poison and a peculiar albuminoid which causes it to become externally hard on exposure to the air. The process of hardening takes place much more rapidiy in the presence of moisture, and in the process of manufacture, freshly lacquered articles are covered with wet matting to hasten the process of drying. The trees are cultivated in vast groves, and cuts are made in the bark from which the juice exudes and is gathered. Twenty pounds from one thousand trees is considered a good yield for one night. When applied as a varnish it is mixed with various substances, as pig's gall, vinegar and coloring matter known to certain guilds and clans, and its peculiar property is its hardness. It resists all known solvents and when old will stand almost any amount of violence without scratching or marring.

The susceptibility of different persons to the poisonous qualities of the lacquer varies greatly. Some enjoy perfect immunity, while others cannot enter a room where a freshly lacquered piece of furniture is standing, or pass a clump of varnish trees without experiencing headache, fullness of the head or vertigo. A tolerance can be acquired for it as seen by those who work with it and gather it, although the latter usually cover up face and hands while at work.

Contact of the varnish with the skin causes an eruption similar to that of *Rhus Toxicodendron*, and identical with that of cashew nut. Minute vesicles first appear situated upon a red and inflamed base. They are generally packed closely together and are accompanied by intense itching and burning and a good deal of pain. In from ten to twenty-four hours the deeper tissues swell to a considerable degree, closing the eyes if the face be affected, or rendering a hand useless. The vesicles coalesce forming good sized bullæ, and in about ten days, which is the usual course of the disease, dry down. The skin pulls off, the swelling disappears and no trace of the disorder is left behind.

In the matter of treatment the native Chinese doctors apply a lotion of cinnabar, a favorite application in all skin diseases. This it is needless to say does little good. Carbolized oil is very good, applied over the affected parts, and a carbolized emulsion of either sweet oil or peanut oil with lime water is excellent. In the last case which I saw, stupes of boric acid were applied and the part was bathed or immersed in hot solution of boric acid. This gave more relief than anything else. I regret not having grindelia orbusta in stock as that is said to be a specific in *Rhus Toxicodendron* poisoning. The similarity of the eruption and the close alliance of the species would warrant a trial.

My attention was called some time ago by Dr. Walter J. Cree, of Detroit, to a certain relation existing between complexion and laceration of the perineum and cracked nipples. My observations entirely coincide with his, and I am curious to know if others have observed the same thing. In red-haired women and those brunettes who have red lips, red cheeks, and are inclined to freckle rather than to tan, lacerated perineum and cracked nipples occur most frequently. And in those sallow skinned blondes who tan rather that freckle and who have a tendency to a deposit of pigment in the areola of the nipple, about the neck and armpits are least liable to suffer from these accidents. The first class seem to have friable tissues and thin skin, and the second, tough muscles and thick skin. Other women are liable to suffer or are able to resist as they lean toward one type or the other. This relation is to me marked, and is of value in prophylaxis.

Coffee as a beverage is an agent of considerable potency in drying up the milk of nursing women. In an institution of which I had charge recently in which there were some thirty or so nursing women, coffee was served twice a week. Regularly upon these days the nurses in charge reported a scarcity of breast-milk and there was frequently a necessity for resorting to artificial feeding to eke out. There is every reason why coffee should be an excellent agent in reducing the flow of milk, for caffeine is one of the best known duretics. I have not been able to ascertain the exact mode of action, and whether it is by reducing the amount of fluid in body through the kidneys I do not know, but it seems to have this effect in a marked degree, and is a valuable adjunct to other agents in reducing excessive flow of milk. In the lying-in period, and at the time of weaning, when the breasts secrete more milk than is wanted, and when the mother is abstaining from fluids, her thirst might be quenched with coffee (providing it does not interfere with her sleep), with good result.

Whooping cough is called the "hundred day disease" in Japan.

THE TREATMENT OF ABORTION.

When abortion is threatened, D. W. W. Seymour (*Am. Gyn. Journal,*) keeps the patient in bed, gives full doses of opium, and if necessary fluid extract of black haw. In the early stages this usually suffices. To control the hæmorrhage he uses a tampon of iodoform gauze, as it can be left in place longer without danger than any other material; however it is never allowed to remain longer than twenty-four hours. When abortion becomes inevitable he cleans out the uterus thoroughly. He precedes examination by a thorough antiseptic douche of the external parts as well as the vagina. If necessary he dilates the uterus with a mechanical dilator, never with tents, introduces a Martin's curette or a polypus forceps and removes its contents thoroughly. The success of his treatment is demonstrated by his record of one hundred and fifty cases, in which there was no death and no septic condition developed after the operation.—*Western Med. Rep.*, *Canada Lancet.*

A NEW TREATMENT OF PROSTATIC HYPERTROPHY.*

By G. BETTON MASSEY, M. D,
PHILADELPHIA.

A proper presentation of the subject of the electrical treatment of prostatic inflammation and hypertrophy is divisible into several general propositions and statements. The first and most important statement that I wish to impress upon you is that the methods about to be advocated may be relied upon as a successful mode of dealing with most cases of this troublesome affections. No method is worth the words to describe it unless this is more or less true, yet in this instance the claim of efficiency is specially noteworthy as the affection under consideration is generally regarded as incurable, and condemning its victims to merely mitigated misery for the balance of their days.

The second proposition may be put in the form of the question: Why and how does electricity cure these cases when properly applied? To answer this we must consider the nature of the morbid process and the character of the tissue involved, and apply to these facts the therapeutic deduction derived from the action of electricity in other analogous structures and affections. The prostate gland is a musculo-glandular body, the glandular tissue forming the bulk of its stroma, through which a multitude of muscular fibrils lace and interlace. The glandular tissue is in direct communication by continuity of structure with the glandular lining of the prostatic urethra. The affection under consideration—acute prostatitis and its sequelæ—does not differ essentially from such catarrhal affections as endometritis, rhinitis and other subacute inflammations of glandular mucous membranes; and most probably is caused or accompanied by the same microbic manifestations as those affections. The utility of the direct application of the galvanic current in combating the disease would therefore suggest itself to any one who has observed its value in endometritis. Of the suggestions to be derived from a parallel treatment of rhinitis I shall not speak beyond mention of a series of experiments now being conducted by the speaker which already prove that nasal catarrh is a field of vast importance to the electro-peutist. Mildly cauterant of morbid surfaces and stimulant to the tissue changes of the whole organ, the direct application of the galvanic current to the prostatic urethra is quickly beneficial in changing the character of the morbid process in the glandular tissue. In addition to this resolvent action, another element of remedial power lies in the contractile effect of swelling currents on the muscular fibres so liberally supplied to the organ. It is the development of this constringent power of electric currents in the hypertrophied gland that forms the chief feature of my method, and as it is a most important feature in certain cases I have felt amply justified in designating the method a new treatment, without detriment to the credit due among others, to one of the fellows of this society, Dr. Robert Newman, who has done so much to attract attention to the value of electricity in prostatic disorders. I have seen little or no mention of the prostate as a muscular organ, and a recognition of this important fact is, in my opinion, the keynote to the most successful management of prostatic hypertrophy.

This catarrhal inflammation and hypertrophy are manifested in an organ closely analogous to the uterus, and in its several varieties and consequences, such as hyperplasia proper, true fibrosis, and myo-fibromatous neoplasms. We have almost exactly analogous affections with those occuring in that organ. This being so, it merely follows that the curative treatment must also be analogous. Currents of five and eighteen milliamperes, while useful in combatting the more superficial prostatitis will not cure the hypertrophies. As in fibroids of the uterus, we must bring the hypertrophied and degenerated organ under the influence of from 20 to 70 ma. This I have done frequently, the active pole, negative, being within the prostatic urethra, and the indefferent pad on the back. The only precautions used, in addition to scrupulous cleanliness of the electrode and gentleness of its insertion, being that the current was not permitted to remain at its strongest figure more than a few seconds, as it was turned on and off at the controller to get the greatest constringing action with the least electrolytic irritation. If this be repeated not oftener than five days no irritation will re-

*Read before the American Electro-Therapeutic Association, October 4th, 1892.

sult, but rather a feeling of relief. In the intervals the same current strength is applied daily in the same manner through the rectal wall, the active electrode being an olive of proper size inserted into the rectum and pressed against the prostate, while the indifferent pad is on the abdomen. The primary faradic current should be used after the same method at each sitting, and I am inclined to look on it is an important adjuvant.

Under this treatment the shrinkage of the organ as a whole is soon manifest to the rectal touch, and as soon as a sufficient absorption of morbid products has occurred, with regression of interfering nodules and collars, the power and freedom of micturition will return.

During the progress of the curative treatment the catheter is passed as often as required, the instrument used for treatment serving the purpose of a catheter also at that sitting. Antiseptic flushing of the bladder is also not neglected at such intervals as the condition of the bladder demands.

A point of additional importance in the use of swelling currents of both varieties in prostatic disease is the fact that the expulsive power of the bladder is always below par in these troubles, sometimes overshadowing the condition of the gland itself, and for this condition the treatment described is of great value.

The effect of this treatment is greatest in the symmetrical enlargements of the gland, as it is in this variety that the muscular substance is capable of greatest response. In fibroid nodules in one lobe of the prostate the older method of continuous application is possibly the best, or we may resort to electro-puncture, though this last resort is undesirable on account of the difficulty of maintaining asepsis.

The instrument shown you is made from a silver catheter with large curve, which has been insulated everywhere with fused hard rubber except a bare surface about two centimeters long just back of the eye. Besides having the advantage of serving as a catheter, and thus saving double instrumentation, the eye at the end serves to notify us of the exact position of the bare spot previous to turning the current on. One of the chief advantages of this form of electrode is the ease with which it may be asepticised by heating in the flame of an alcohol lamp, the same heating permitting us also to repair any break that may have occurred in the thin hard rubber coating of the instrument.

THE VALUE OF RESORCIN IN GASTRIC ULCERS.

In the *Provincial Medical Journal* for May 2, 1892, Pope, of Leicester, records the results which he has obtained in the treatment of gastric ulcer by means of resorcin, referring to a paper by Dr. Mackey, of Brighton, which was published in the *Lancet*, vol. i. p. 570, who treated fifteen cases by this method, using 5 grains three times a day. In Mackey's cases it proved very valuable in fourteen. Its employment is based upon the fact that it is antiseptic, analgesic,and hæmostatic. Pope believes that its analgesic property is most valuable, as by this means the stomach is able to tolerate food, when otherwise it would be excessively sensitive, ulcerated or eroded. The antiseptic effect which it produces is valuable in the prevention of fermentation.

The ordinary dose is 5 grains three times a day. Pope also states that he has found resorcin of value in gastric cancer. Under its use he has seen foul tongues become clean, and stomachs which formerly rejected almost all food become tolerant. Under these circumstances, however, it is a drug which modifies the symptoms rather than the disease itself.

THE TREATMENT OF ASTHMA.

Dieulafoy (*L' Union Mèdicale*, No. 48), says: At the onset of a paroxysm by means of a brush an application of a 5 per cent. solution cocaine hydrochlorate is made to the nasal fossæ as high as possible, or the throat may for four or five minutes be sprayed with the same solution. Should the attack not be aborted, from six to twelve drops of pyridine on a handkerchief should be inhaled. If the attack has reached its acme, a twelfth grain of morphine hydrochlorate is administered hypodermatically, if necessary repeated at an interval of a quarter of an hour. For the constitutional condition, potassium iodide, belladonna, and arsenic are indicated In case of emphysema, baths of compressed air should be employed.—*Medical News.*

REMOVAL OF FRAGMENT OF BONE FROM ŒSOPHAGUS THROUGH THE PHARYNX.

A. L. BENEDICT, A. M., M. D.,

ATTENDANT, DEPARTMENT OF GENERAL PRACTICE AND DIGESTIVE DISEASES, FITCH DISPENSARY; CONSULTANT IN DIGESTIVE DISEASES, INGLESIDE HOME HOSPITAL, BUFFALO.

Last month I was called to attend a married woman, aged 50, who said that at breakfast four hours before, she had tried to swallow a piece of meat which had lodged in her throat. The patient had drunk beer with the hope that it would nauseate her—according to her own statement. Other members of the household informed me, however, that she was in the habit of drinking considerable, though she was not positively intemperate. She was in a nervous, almost hysterical state with the feeling of something lodged in the throat at about the level of the greater cornua of the hyoid. A laryngoscopic examination showed that the throat was clear but that there was some chronic pharyngitis, that the tonsils were enlarged and that there were masses of tonsillar tissue on either side of the base of the tongue which might have acted as irritants and which, I was inclined to think, were the cause of the symptoms of which the patient complained since she was certain that she had swallowed no hard substance and that there was no bone in the meat of which she ate at breakfast. Accordingly, after prescribing an astringent gargle and administering a gram dose of potassium bromide, I was about to leave the house when the symptoms became aggrated, the patient gagging and breathing with difficulty. A digital examination of the pharynx and œsophagus was then made, the patient having the least irritable throat which I have ever encountered. The epiglottos, rima glottis, arytenoid cartilages, tonsils and other parts of the throat were carefully explored and then the finger was passed into the œsophagus as far as it would reach and it just touched the upper part of some foreign body. An attempt to remove the obstacle with long curved forceps failed. The patient was then placed face downward on a bed with the head hanging over the edge. Partly by the aid of my finger in the throat, partly by the patient's efforts at vomiting, the foreign body was removed. Notwithstanding the patient's previous statement, it proved to be a fragment of a pork rib, one inch long, three eighths wide, rounded at one end, sharp at the other. No unpleasant after-effects were noted.

CALOMEL IN HÆMORRHOIDS.

For a number of years Dr. J. B. James, of London, has treated hæmorrhoids by the simple process of applying calomel to them with the finger, and claims to have done so with marked success in every case, particularly when the hæmorrhoidal mass was inflamed, which is characterized by mucus discharge and hæmorrhage, accompanied by a painful sensation of weight in the region of the rectum. All these symptoms, it is alleged, were speedily relieved by the simple application of the calomel, which had the still more important subsequent advantage of restoring the patient to perfect ease, enabling him to pursue his usual occupation in happy immunity from all distressing or annoying symptoms.—*Merck's Bulletin*, May, 1892, p. 277.

BORATE OF SODA IN EPILEPSY.

Dr. Mairet finds that compared with the bromide of potassium, the borate of soda is of real value in the treatment of epilepsy. The attacks decrease under its use, and may be suppressed even for many months at a time. It acts better than the bromide of potash in symptomatic epilepsy. The bromide, on the contrary, gives better results than the borate of soda in nervous epilepsies, and in cases of this order it is only when the bromide has failed that borax should be tried.—*Le Progrès Médical.*

PRURITUS ANI.

Dr. Balfour (*Norsk Magazin for Lægevidenskaben*, No. 1, 1892) employs the following formula with success in pruritis ani:

℞ Calomel.....gms. 5.
Vaseline.....gms. 35.

Instead of vaseline one may use lanoline, which of itself acts well in pruritus.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of September 1st, 1892.

The President, Dr. W. H. H. Githens, in the chair.

Dr. Joseph Price presented a paper on "Section for Removal of Tumors Following the use of Electricity." The doctor said that, with our abundant and continually increasing data, we are growing in ability to discuss the question of the value of electro-therapeutics in gynecology with more intelligence. Just where the claims of the electricians are to stop is problematic. The utter failure of many of their claims does not seem to embarrass them. We are led to believe that there is no abdominal or pelvic trouble that the galvanic current is unable to cure. The method of treatment, the operative work, of none of us is uniformly successful, but our surgeons in their work have results that speak for themselves—while in the electric treatment, the failures are repeated and signal. To start with, the treatment is troublesome and tedious, much more so than surgical operation, and it delays, prolongs and generally complicates, where prompt surgical procedure expedites and saves. Up to date, the advocates of the electrical treatment have not furnished a single instance in which the tumor has disappeared, where the disappearance could positively, beyond reasonable doubt, be credited to electric treatment. At the meeting of the American Gynecological Society, held in New York in September 1887, Dr. Apostoli was asked the pointed question: "Have you ever seen a tumor disappear under your treatment?" His answer was manly and frank, "I have not." All he could claim, all he did claim, was amelioration of symptoms. Opium will ameliorate symptoms and at the same time have a like effect with electricity in complicating the trouble. In tumors the claim is "reduction in size." The surgeon's claim is total extirpation, and restoration to health and usefulness. Another claim is "greatly benefited." This could be done by careful general treatment, keeping the bowels open, rest, particularly at the periods.

An eminent English gynecologist says, "The changes following galvano-puncture will be found immediately around the seat of puncture, but similar changes would follow if the thermo-cautery or red-hot iron had been used. In any case the changes are extremely local and do not extend into the substance of the tumor. In some cases the current has no effect whatever on the tumor. In other cases it causes sloughing. This was followed sometimes by absorption of the tumor and sometimes not. In either case the patient was subjected to all the danger of peritonitis, septicæmia, thrombosis, embolism, etc."

An electrician claims that in the treatment of extra-uterine gestation, "it stands with a record unblemished by a single failure or any dangerous consequences." Now, on the subject of extra-uterine pregnancy, Mr. Tait, with the characteristic bluntness of the surgeon, says, "To apply the electric current to every kind of a lump in the pelvis under the suspicion that it is an extra-uterine pregnancy, would be a most haphazard, dangerous proceeding, worthy of the strongest condemnation." He "considered the use of the electric-current as one of the most nonsensical proposals that had ever been suggested to a surgical audience." He said that it was absurd to attribute the maceration of the fœtus to the electric current. When rupture took place, he often found a macerated fœtus, with bones extensively laid bare. In that case the fœtus must have been dead for weeks before the current was applied. And as to the growth of the placenta, the cases he had seen were those in which he had found a macerated fœtus not more than ten or twelve weeks old, while the placenta was the size of a four months' pregnancy. This opinion was confirmed by Dr. Berry Hart and Mr. Knowlsley Thornton.

As to the diagnostic properties and functions of electricity, there is solid ground for our scepticism. Operators with a varied and extended surgical experience and with a clinical knowledge of the multiple nature of pelvic and abdominal disease, have a right to question the ability of the great majority of the followers of the electric treatment to diagnose pelvic and abdominal disease within defined lines of reasonable certainty.

DISCUSSION.

Dr. G. Betton Massey said that as he did not hear the first part of the paper, he wanted to say that his remarks are to be taken in ignorance of the first half of the paper. The paper clearly shows that Dr. Price is opposed to electricity in gynecology. He preferred to see cases from a surgeon who takes that stand, for he had been so unfortunate as to have had some cases from surgeons who believe everything is good and that they are good for everything and that they had as good ability to apply the delicate and powerful agent electricity for the cure of bleeding and large tumors as they had to cut the tumor out with a knife.

The portion of the paper that he heard was simply an attempt to hold up to derision, the claims made for electricity in the cure of fibroids and also the explanation of those claims; but so far as he could see it the derision was merely in the sense that you choose to take it. The claims which were held up to derision, he wished to stand by and point out as true in skilled hands. A man can not get up and say that there is nothing in electricity unless he can tell the difference between the effect of the positive and the negative pole properly applied. He shows that he is ignorant of the first principles unless he can discuss them.

It is folly for any one to compare the removal of the ovaries in fibroid cases with the administration of electricity. The one has been demonstrated by those who have mastered the subject as almost invariably valuable—that is, nearly one hundred per cent. of the cases are benefited more or less. The other, the removal of the ovaries is a pure experiment. Who can say of any given case, that it will be better at the menopause? Hence, who can say that after the removal, the dangerous removal, of these inoffending organs the patient will be better. He knew himself from considerable experience that oophorectomy for fibroids is largely an unnecessary experiment and largely a failure.

And as to the electrical treatment: should any one wish to know about that they should not stop at the opinions of an opponent. He had treated sixty-eight cases of fibroid tumors with electricity, some not well adapted to that agent, as it is now well conceded that there are certain tumors that are not well adapted to the use of electricity. Of these sixty-eight cases, sixty-four were decidedly benefited in spite of the fact that many of them were treated before the time had arrived when he knew how to select these cases. Sixty-four cases were satisfied not to undergo any further treatment, and were satisfied as to the money and time spent. From the point of view of the arrest of the growth, he believed from his present information of these sixty-four cases, that the growth has been permanently arrested. They are therefore successes in that point of view. They have all been successes from the point of view of the removal of pain and pressure symptoms. They were nearly all successes from the point of view of reduction in size, many of them being largely reduced, although he warned them that such good results can only be gotten by patient work.

In these sixty-four cases, the tumor totally disappeared in seven. In one the tumor was as large as his head. That case has been thoroughly spoken of and reported in another society. In view of that statement it seems folly for any sensible man to say that the electrical treatment of fibroid tumors is unwise and is useless. He was prepared to exhibit that patient to any one who wishes to see her and also to furnish the measurements taken by her physician when she was first placed under his treatment.

Dr. B. F. Baer believed that we want the truth in regard to electricity in the treatment of fibroid tumors and its effect on subsequent surgical treatment. In his own experience he had found that the most difficult cases of fibroids that he had operated on had been cases that had previously been treated by electricity. He did not wish to state that the electric treatment was the cause of the case being the more difficult, because he could not prove it, but that not only did electricity fail to cure these tumors, but, for some reason during the conduct of the treatment, these patients had from one to a dozen attacks of peritonitis around the tumor. The growths were universally adherent. One sloughed and one contained a large quantity of pus and three had evidence of inspissated pus around the tumor. In no single case treated by electricity had he seen more than temporary benefit result. He thought that Dr. Massey had no right to claim that the patient was benefited by

electricity and would not have been benefited by the remedies which long ago we learned would benefit these cases, such as the application of some stimulus, as of iodine, or the curette, safely and mildly applied. These agents we used long before electricity was employed or hysterectomies done. We benefited these cases. We modified the hæmorrhage and in some cases thought that we cured the hæmorrhage by remedies applied to the interior of the womb. With the curette we did harm in many cases, but we controlled the hæmorrhage. We did the same with ergot, chloride of ammonia, rest, clay-pads.

After his last year's experience, he would use surgery instead of electricity. If any friend of his requested treatment, he should emphatically urge surgery even in small tumors.

In regard to what Dr. Massey said with reference to oophorectomy. This does not give the good results he once thought that it did, or hoped that it would. In his own experience oophorectomy for fibroid tumors had not been a successful operation. He could not see why he should use oophorectomy when hysterectomy is so easy. He should feel that the patient was safer after hysterectomy than after the ovaries were removed.

Dr. Joseph Hoffman said that in the treatment of fibroid tumors by electricity it will always be a question as to what the electricians mean by a fibroid. He thought Skene Keith quite as good an authority on electricity and its application to fibroids as other gentlemen who claim as much he does. Dr. Hoffman did not believe that there were five consecutive cases in the last book that Dr. Keith has written that would be accepted by the surgeon as cures of fibroid tumors such as Dr. Price exhibited. At one of the last meetings of the Society, Dr. Massey had reported a case of tumor diminished by the use of electricity—a one-sided tumor the nature of which was puzzling. But, to everyone in the society except the electrician, it was clearly a fæcal mass in a distended colon. If, in a case like this, there is doubt in the electrician's mind as to what he is treating, is there not good reason for doubt in the mind of the surgeon that some of these cases, regarded as fibroids, are something else ?

Then again about time. Time is in many cases an important element. It is an important element not only to the electrician but to the woman and to the surgeon and Dr. Hoffman held that if a radical cure can be demonstrated as possible in the great majority of these cases, operation is from the point of time preferable, since the mortality comes down to almost nil.

Another point, the desire to do hysterectomy and the frequency with which it is done. If the two books, the one by the elder Keith and that by the younger Keith, are compared, no one in his senses can challenge their relative importance. The one is an earnest, successful, scientific work, the other is tentatively trying experiments. The one gives results, the other asserts that he gets results but there is nothing in the way of proof. Remember that the surgeon does not do a hysterectomy in every case.—The argument seems to be that every case that presents itself to the electrician has just escaped the surgeon by the skin of its teeth. Such is not the fact. He had walked by the side of Dr. Price when he did not do hysterectomy. It was a scientific point to be settled and the result has been one of weighing the chances, considering the nature of the tumors and the condition of the patient—the weighing of the power of electricity to do mischief or to afford benefit.

He agreed with Dr. Baer that he had seen an abscess containing quarts of pus started up by electricity. He had too a vivid recollection of a case in which this undoubtedly was a fact. A large fibroid tumor without any symptoms whatever treated by electricity, followed by the formation of pus and death. The smaller tumors are the most easily removed. The larger tumors are the dangerous ones and still there has been a great deal said about the choosing of the tumor to which electricity is to be applied. There is no electrician living who can tell when he has a tumor to which he can apply electricity without harm and danger to the patient—this agent which is believed to be so harmless.

Dr. George I. McKelway said that before saying anything in regard to the subject under discussion, he wished to do Dr. Massey the justice of correcting a mistake that Dr. Hoffman had made. In the case of the fæcal mass, Dr. Massey did not diagnose it a fibroid tumor, but sarcoma of the ovary. He thought that Dr. Massey should have the justice of the correction.

He had been a member of this society for years but he had been a quiet one. He thought that this was the first time that he had opened his mouth in it. He had listened quietly and had thought patiently of many things. Sometimes he had been instructed, sometimes amused, sometimes he had been provoked and sometimes he had been surprised. It was largely in the line of the discussion of electrical matters that he had been surprised.

There are some words that are words to conjure with. We have a striking example of that just now not only in this country but all over the world in bichloride of gold. If Keeley had talked about the bichloride of lead he never would have had any one come to be cured. If he had talked about bichloride of tin he never would have been heard of. He talks about bichloride of gold and people flock by multitudes.

It is much so with this word electricity. It is a great thing. People think of Edison, of the Atlantic cable. Electricity is a word to conjure with and it has been conjured with a great deal.

Something has been said about the amelioration of symptoms. He had seen symptoms ameliorated in a most surprising way by a hypodermic injection of ten minims of water.

He did not want to discuss a thing the discussion of which he had condemned, but it had always seemed to him a little peculiar that this society or any society like it, supposed to be a scientific society, should give its time, meeting after meeting, to the discussion of the use of electricity in gynecology.

Dr. Joseph Price said that Dr. McKelway had covered beautifully some points in condemnation of just what he had been condemning; he felt that he owed the Society an apology for squandering its valuable time, but he had dealt with a huge number of tumors during the past summer and he felt that the surgery was greatly complicated by the use or the abuse of electricity and wanted to have a full and complete discussion of the subject that they might have a more accurate knowledge of the mischief done by electricity.

In regard to sloughing-fibroids, the electrician can assert that under any treatment, or without treatment, fibroids may slough and become gangrenous. This is true, but the larger number behave badly, slough, become adherent and undergo retrograde changes after the application of electricity. His position is that of Dr. Baer, of all of us in fact. Years ago we were timid, we were cowardly. Now Dr. Baer removes a fibroid-tumor because he feels that it is his duty to do so and because he knows how. He feels that it is his duty to remove it early, while the patient is in good health and all the conditions are favorable to a speedy recovery.

An allusion has been made to surgery. Much of the fibroid-surgery is bad. It begins in doubt and ends in disaster. Some of our operators are not prepared to do hysterectomy. We have had much discussion about pedicles; why should one who makes a pedicle discuss the subject with one who does not know how to make a pedicle? He could not do a hysterectomy without making a pedicle. The man who delivers a big fibroid with a pedicle as large as his coat-sleeve and places a clamp around it and screws it up and says he has difficulty in closing the incision and has to make a pedicle out of the tumor is one that knows nothing about hysterectomy. Unless he can go to the internal os and make a small pedicle fitting the lowest angle of the incision, he knows nothing about hysterectomy. The man who has never done a complete-extirpation has no right to discuss the subject with one who has done it a number of times. The man who never dropped the pedicle cannot discuss the subject with Martin, who drops them all. The man who has not made a complete-extirpation cannot discuss the subject with Dr. Baer who has done it a number of times.

Coming back to the pathology which is the most important point in the natural history of fibroid tumors, the pathology has changed greatly in the last thirty years. The pathology of all gynecology has changed. In Africa these tumors are unknown. In America they are exceedingly common. In Sir James Y. Simpson's clinic thirty years ago, they were scarcely seen. Now in Edinburgh they are numerous and behave badly. The same is true in his own experience. He was not prepared to say why this is so.

Dr. Massey claims benefit in nearly one hundred per cent. of the cases and then he tells us that a number of the sixty-five cases were not suitable for electricity; they had passed that period. It will be

interesting to know what became of these sixty-five cases. One of the ladies with a huge tumor whom Dr. Massey had treated was in his office and had it not been that two prominent electricians had discouraged this woman as to the prospect from surgery, she would have had the tumor removed. It is a common practice with some physicians to tell patients not to let any one touch them with a knife, saying that even if the abdomen is opened, the tumor cannot be removed. He had never in his office condemned electricity or any other treatment, except that he had advised patients to leave matters alone.

Dr. Marie B. Werner presented a paper on the "Analysis of Some Statistics on Supra-vaginal Hysterectomy." The Doctor stated that the three methods of treating the stump are meeting with varied results in the hands of different operators, and it becomes therefore an important matter to study method and operator together. The intra-peritoneal seems theoretically the ideal, but the general results fail to show the low rate of mortality necessary to place it foremost. Bantock abandoned it after careful study, on account of the great mortality. Schrœder and Martin both had a high mortality by this method and Martin abandoned it for total extirpation. The fact remains and must be always kept in mind, namely, the want of reliability in the ligature and the peculiar nature of the uterine tissue. The extra-peritoneal method gives the lowest rate of mortality and for this reason the method is the most promising. All the details are of paramount importance in this operation if it is to be successful. The operator must be prepared for every emergency before beginning to operate and complete the operation, when once begun. The doctor insisted on the complete removal of the tumor. She stated that there were several cases on record in which a portion of the tumor was allowed to be expelled through the abdominal opening. The danger of sepsis is very apparent. The ligatures should always be applied to healthy structures and this holds good in hysterectomy as well as in the removal of diseased appendages. The operator should work aseptically, surely and rapidly (consistently with good judgment) leaving if possible no ragged surfaces for subsequent sloughing. A small extra-peritoneal stump always gives the best results.

When the growth has originated low down in the uterus and developed laterally, filling up the pelvis, it is a difficult task to make a stump. Anatomical relations are to be studied and kept in mind, the tumor raised as much as possible out of its bed, adhesions released and properly cared for, the peritoneal covering incised three or four inches above the point where the nœud is placed, then stripped down; the enucleation of the tumor becomes an easy matter, comparatively, and the nœud is placed around uterine tissue and not fibrous. Not only is the stump much reduced in this manner but the danger of hæmorrhage and sepsis is minimized; there are still two other complications which are easily avoided by so doing: injuries to ureters or bladder.

Chrobak's results with total extirpation have certainly been most promising—four, with no deaths—and also in his later modification of retro-peritoneal fixation treatment of the stump—thirteen without a death. He abandoned total extirpation for the latter method on account of saving the time. E. Albert, of Vienna, reports fifty cases with three deaths, the stump treated in the way that Chrobak recommends. In total extirpation there are still some points that time alone will settle; the ultimate behavior of the bladder and vaginal roof, since both have often been much stretched and displaced by the growths removed.

DISCUSSION.

Dr. Joseph Price said that the discussion of the pedicle was always of interest and importance. The method of transfixion and the use of the wire or ligature were at first imperfect, but later the application of the ligature was perfected. Some operators, as Dr. Cushing, of Boston, prefer the elastic ligature and, Dr. Price did not know but that he succeeds better than with the wire. When constriction is depended upon, the ligature gives a constant and continuous pressure. With the application of the wire you have shrinkage and have to screw up the clamp. Hysterectomy is a piece of civil-engineering. He could not have done this work without special training. Applying forceps to serve as land-marks, you drop down the capsule and, beginning with a pedicle as large as your coat-sleeve, you end with one as large as your thumb. You need

not fear hæmorrhage. The elastic-ligature is not necessary. It prolongs the operation. In almost any method of hysterectomy you can get along with a few hæmostatic-forceps without the temporary clamp. There is a certain amount of work in the use of temporary-constrictors that you have to do over again. In cases of multiple-fibroids it is of great importance that the pedicle should be made in the way described. The bladder may come up between two of the tumors and unless you strip off the capsule until you come to the cervix there will be risk of catching the fundus of the bladder. In one of his cases he included the fundus of the bladder but the patient recovered. Mr. Tait did it in Albany but the patient recovered although there was a fistula which lasted for months. After applying the wire you must bring in the margin of the capsule and let it be caught by the wire.

Dr. Joseph Price also reported several cases of extra-uterine pregnancy.

He stated that he would refer to *tubal* pregnancy only, as he believed it to be the only variety, although, after rupture, it may be found anywhere in the pelvis or abdomen. He referred briefly to some of the most prominent points of this murderous accident—First, that it is common and on the increase. Secondly, that it is easy of recognition. Thirdly, that there is but one treatment. As to frequency: Pathological conditions favoring its occurrence are distressingly common and on the increase. From his experience he would say that tubal pregnancy was much more common in the cities than in rural districts. In regard to early recognition or diagnosis, he now worked by a method of exclusion, looking first for tubal pregnancy—as the most serious and dangerous trouble a woman can suffer with. Second, for appendicitis. Third, for pus in tubes or ovaries. Fourth, for suppurating dermoids, twisted pedicle, etc. He rarely failed to recognize tubal pregnancy where it exists. He thought it only fair to say that the general practitioner has given and is giving this vital subject much careful reading and thoughtful consideration. He is generally the first to see this class of cases and the skillful general practitioner is not slow in recognizing the existing trouble and is prompt to call in surgical aid.

Secretary,

Abstracts.

DYSTOCHIA FROM IMPACTION OF THE SHOULDERS.

Dr. Kortright says: That difficulty of delivering the shoulders after the birth of the head does occasionally occur, the following list of accidents will prove: Rupture of the fibres of the sterno-cleido-mastoid muscle with subsequent abscess of the neck, injury to the brachial plexus followed by temporary paralysis of the arm, fracture of the shaft of the humerus or separation of its epiphysis, cerebral effusion, or asphyxia, with consequent death of the child. Incredible as it may seem, the head of the child was torn off in endeavors to deliver the trunk when the shoulders had become impacted.

We frequently find multiparæ of the following character: They are wives of poor men and have borne their husbands from four to nine children at the regular tenement-house interval. In their youth, they were slender girls of less than the average height and have married early. Their sylph-like proportions have long since disappeared so that they present the large limbed, full bosomed cuboidal aspect with which we are all familiar. Repeated child bearing has caused separation of the abdominal recti, weakness of the oblique abdominal muscles, subinvolution of the abdominal walls so that the uterus falls forward when enlarged, and what they call their high stomachs become markedly accentuated during pregnancy. There may be no suspicion of rachitis about them, but their pelves are very shallow, the pubic rami widely divergent and one or all of the pelvic diameters small. When they stand erect, the axis of the uterus is nearer the horizontal than the perpendicular. If one has occasion to remove an adherent placenta from such a uterus he will be painfully impressed by the extreme extension of the hand necessary to reach the interior border of the placenta, or the anterior uterine wall. These women, bear, as a rule, large children which frequently present in the occipito-posterior position.

When such a person comes in labor, the head engages badly, progress is slow, and even if the forceps be used the uterus is in a condition of partial inertia by the time the head is delivered. The pains are in-

efficient to deliver the large body. One shoulder is caught above the symphysis at the angle of the parturient canal, the other is at the promontory of the sacrum or slightly below it. The head of the child is extended and laterally flexed at a right angle to the trunk.

It is just this condition concerning which so little has been written and the best management of which is not to be found in any text-book. It is plain that this position of the child is one of great danger; for the pressure of the maternal parts upon the body of the child without any corresponding pressure upon its head soon leads to death from asphyxia or effusion within the skull. We are all familiar with the cyanotic face and the pouting lips of a child in this position. Jacquemier, the first to mention this variety of dystochia, treated it by bringing down the arms and extending them over the head, but this method is acknowledged by himself and others writers to be difficult and to cause fracture of the arms. Hodge advises pressing the child's neck against the symphysis and in this manner bringing the posterior shoulder to the edge of the perinæum. When the posterior shoulder appears the child is to be carried backward and the anterior shoulder disengaged. Parvin advises traction with the finger in the axilla of the perineal shoulder or with the finger in each axilla. Lusk advises traction upon the sides of the head, or with the finger in the axilla. Mann advises pressing the neck backward upon the perinæum with traction till the anterior shoulder appears under the symphysis, and then forward pressure till the posterior shoulder is born. This is all that is written upon the subject.

By means of any of these procedures we would be able to deliver in the great majority of cases, but in none of them does the proper rationale obtain. How does nature relieve herself in this condition? In the *Medical Recorder*, vol. 37, p. 444, may be found the report of a case of impaction of the shoulders in which the pains were strong and delivery took place without external aid. In this case restitution was toward the right thigh of the mother. The face then turned backward toward the perinæum until it looked toward the left thigh. By this semi-revolution the posterior shoulder passed under the symphysis pubis and the anterior shoulder passed into the hollow of the sacrum. The mechanism was exactly analogous to that which obtains in most cases of occipito-posterior presentation of the vertex. This spontaneous rotation then is nature's solution of the problem and should furnish us a proper basis of treatment. Bearing in mind that the shoulders engage in the oblique diameter of the pelvis we should endeavor to rotate the child in the direction of the least resistance. And this direction will be that in which the anteriorly lodged shoulder passes away from the medial line of the mother and not toward it.

In practice this rotation will be best accomplished in this manner: Introduce the finger of the hand corresponding to the maternal thigh toward which the child is looking. If the restitution has been toward the right thigh use the right hand and conversely. The finger thus introduced will enter the axilla of the posterior shoulder on its dorsal aspect. Pull the shoulder sidewise and toward the symphysis. Do not push but pull. Make the dorsal side of the posterior shoulder the advancing surface. In this way the anterior shoulder is pushed away from the symphysis and is not crowded against it. Passing into the transverse diameter the shoulder glides into the hollow of the sacrum, thence to sweep over the perinæum.

This proposed method of unlocking the impacted shoulder is not mere theoretical reasoning, but has stood the test of actual experience. Previous to its adoption I had had one case of paralysis of the arm from injury to the brachial plexus caused by traction on the head. I had also lost a child from asphyxia during delay while trying in succession the methods given in the books. Since the adoption of this manœuver, I have had neither accident nor difficulty.

In the discussion Dr. Jewett after speaking in terms of high praise of practical nature of Dr. Kortright's suggestion says: In regard, however, to the management of the complication to which the paper alludes, I have been accustomed to depend upon a method something like this: When the posterior shoulder presents I lift the head well toward the mother's abdomen. I then place the fingers in the posterior axilla and lift that shoulder over the edge of the perinæum, pushing the perinæum gently back. The posterior

arm can then be released. When this has been accomplished, the other shoulder may be delivered usually with no difficulty. In other words, I deliver in detail, the entire bisacromial diameter never being allowed to engage at one time. This method has always served my purpose; yet I fully recognize the fact that there may be cases so difficult that it may fail; and I heartily commend the method of Dr. Kortright and shall hold it in readiness for use when the other does not serve.—*Brooklyn Med. Jour.*

THE CHOLERA, AND HOW TO PREVENT IT.

(ISSUED BY THE TENNESSEE STATE BOARD OF HEALTH.)

To prevent cholera, every one must help. The State Board of Health may issue circulars, and the local authorities may vigorously enforce regulations, but if each householder will not heartily co-operate in removing the causes which breed cholera and similar diseases, the pestilence, should it come, will be rendered many fold more disastrous than if otherwise. The following instructions have been drawn up with care, and explain what ought to be done:

1. To prevent cholera, it is necessary to remove the unsanitary conditions which give fatal activity to the cholera poison.

2. To keep a good heart and a cool head, and observe strictly the laws of health.

"A Dervish, traveling over the desert, met the Cholera, to whom he said, 'Where are you going?' The Cholera replied, 'I'm going to Bagdad to kill 20,000.' Some time after the same Dervish met the Cholera returning, and said, 'You vagabond, you killed 90,000.' 'No, no, said the Cholera, 'I killed 20,000; fear killed the rest.' "—*Oriental Legend.*

3. Prompt attention to all looseness of the bowels will generally prevent an attack of cholera. "To arrest diarrhœa is to prevent cholera." When cholera is about the slightest diarrhœa should be instantly checked. A good diarrhœa mixture, which every one should keep in the house, should be taken at once, a doctor should be sent for immediately, and all evacuations should be disinfected as if the case were one of cholera.

4. The unsanitary conditions which enable the cholera germ to become fatal are: (*a*) A tainted water supply; (*b*) foul privies or cess-pools; (*c*) foul ash-heaps; (*d*) damp, ill-ventilated houses; (*e*) defective drainage, ill-trapped sinks and imperfect sanitary appliances; (*f*) filth in any form.

All springs and wells should be inspected, even if their water is bright and sparkling, for then it may be most dangerous All suspected should be filtered and boiled. All tainted wells and springs should be closed, and whenever a cholera case is reported all drinking water drawn from rivers, springs or wells should be boiled for half an hour. Filtration is good, but it is best to boil afterward. Cisterns should be cleaned at short intervals, and so situated as not to be in close proximity to either drains, privies or cesspools, particularly so if built underground.

Cesspools, or foul privies, are nests for breeding pestilence, and centers for poisoning the earth, the air and the water. It is chiefly by their leakage into wells and underground cisterns, and their overflow into springs, branches and rivers, that they contribute to the propagation of cholera.

7. Damp, dirty, overcrowded houses predispose their inmates to attack. All low-class tenement property, outhouses, cellars, etc., should be thoroughly lime-washed; back yards should be frequently cleansed and disinfected; fresh air and sunshine, if possible, should be let into every room daily. Where there is a smell in any room which cannot be removed by opening the window, something is wrong, which ought at once to be put right, or mischief may follow.

8. The careful disinfection and prompt subsequent removal of dirt, filth, and decayed matter of all sorts, the vigorous use of soap and the scrubbing brush, the constant ventilation of all sleeping and living rooms, and immediate attention to all foul smells, always important, are never more so than when the cholera is hovering around.

9. The ordinary rules of health should be strictly observed in (*a*) cleanliness; (*b*) moderation in all things: (*c*) avoidance of all sources of cold and indigestion. Every one ought to wash from head to foot at least once a week, and the oftener body linen and bed clothes are changed the

better. Never eat with unwashed hands, especially when cases of diarrhœa or cholera are in the house. In the latter case some disinfectant should be added to the water before washing, and food should never be taken in the room with the patient.

10. To minimize the danger of infection it is well to be moderate in all things, particularly avoiding all excesses in drinking, in eating, or in exercise. Excess in drinking, sometimes resorted to from a mistaken idea of warding off the cholera, has the exactly opposite effect. Spirits are useless as a corrective of impure water. Excess in eating, by disorganizing the digestion, predisposes to diseases of the digestive organs, of which cholera is the worst. Eat well, but wisely, and avoid all unripe fruit, indigestible or tainted food, and everything that disagrees with you. Excessive exercise is dangerous, by producing exhaustion; so is prolonged bathing. Everything that causes exhaustion is bad. Avoid all sudden chills, especially when perspiring. Flannels should be worn next the skin. A flannel belt round the waist is strongly recommended. Avoid draughts and late hours,and always wear enough clothes to keep the body warm, especially at night.

11. When cholera or diarrhœa exists in the neighborhood of dairy farms, avoid milk coming from that district, and if other milk cannot be obtained, condensed milk is safer than fresh milk from infested districts.

12. If from any source a case of cholera should develop in any locality in Tennessee danger of its spreading may be minimized by (*a*) immediate isolation of the patient, (*b*) complete disinfection and instant removal of all excretions and other matters that come from him, (*c*) burning or thorough disinfection of all clothes, bedding, etc., soiled by cholera discharge.

13. Cholera secretions should be regarded as more dangerous than strychnine. The vessels into which they are discharged should always contain carbolic acid or other powerful disinfectants; they should be immediately emptied, and the privy, water-closet, sink or drain down which their contents are thrown should be flushed at least once a day with carbolic acid and water, chloride of zinc, sulphate of iron, or other equally effective disinfectants. Do not spare the disinfectants, especially in the case of privies and cess-pools.

14. All clothing,carpets,sheets, towels, etc., which have come in contact with a cholera patient should, if possible, be burned at once. On no account should they be sent to a public laundry or washed in common with the clothing of others. If not burned, before they are sent put them in a tub of boiling water mixed with carbolic acid, and afterward have them, as well as the furniture, etc., thoroughly disinfected by the free use of the fumes of burning stick sulphur, continued for at least four consecutive hours.

15. Do not be frightened. For one who dies of cholera in the worst years two die every year of typhoid and similar preventable diseases. No one who gets into a panic gives himself a chance. Doctors and nurses who are constantly attending cholera patients do not die in greater proportion than others. Prompt treatment of the disease in its early stages is almost always successful.

Please read this document with care, and try to remember the principles involved, and then preserve it for future reference.

TREATMENT OF PYOGENIC AFFECTIONS BY PRODUCTION OF ARTIFICIAL ABSCESSES

Fochier (Lyon) has recently suggested the production of artificial abscesses, by the subcutaneous injection of essence of turpentine, as satisfactory treatment for certain cases of infection. In a number of grave cases of puerperal infecton and of pneumonia he thinks he has seen recovery due entirely to this treatment. Dieulafoy (*Sem. Med.*, March 30, 1892) reports a desperates case of pneumonia successfully treated by Fochier's method. In his case subcutaneous injections of 1 gramme of essence of turpentine were given in each of the four limbs; the following day there was marked improvement in the condition of the patient. L. Bard (*Lyon Med.*, April 17,1892) reports a grave case of pneumonia where recovery was undoubtedly due to the production, artificially, of abscesses.

CHOLERA NOTES.*

MARIE B. WERNER, M. D.,
PHILA.

In Hospital St. Antoine (*Bull. Med. 1892*)—each cholera patient receives a bath on admission, temp. 40° C, lasting from twenty to thirty minutes, to which mustard is added in the latter stage; should reaction fail to take place, transfusion is resorted to; 1500 grammes of artificial serum, 38° C. (Aq. dest. 1000, natr. chlorat. 6, natr. hydric. .05.) This treatment does not include those grave lightning-like cases. Systemic treatment is as follows: 1st Absolute dieting—2nd (a) Sol. acidi. lactici 15:1000, two liters daily—(b) Tea with rum; ice; Seltser water. (c) For persistent vomiting the stomach is washed several times daily with boiled water, and then filled with 500 grms. of lactic acid solution. (d) Every two or three hours a mustard bath is given, same temperature and time as stated above; should faintness or dizziness occur, the patient is placed at once in the horizontal position, using vigorous friction on the chest.

The bath raises the rectal temperature ½ to 2°. The arterial pressure and increased activity of the circulation produces a lessening or disappearance of the cyanosis, and promotes perspiration and sleep, frequently the urine is voided and the cramp relieved during the bath. (e) Should this fail, transfusion is resorted to several times daily. (f) To encourage excretion of urine, the bladder is filled with a warm solution of boric acid. (g) Adjuvants—Caffein, subcutaneous ether injections, oxygen, leeches, cotton wrappings. (h) As soon as the appetite returns, (third day of treatment) coffee, bouillon, and wheat bread are the first given. Milk had frequently produced symptoms of indigestion.—*Deutsche Med. Zeit.*, Sept., 1892.

Neuman (*Deutsch. Med. Woch.* Sept., 1892) desires to direct the attention of the practicing physician to the efficacy of the subcutaneous saline injections used successfully by Cantoni during the cholera epidemic of Italy in 1884. It is necessary to use large quantities of the solution (children 100 to 300 grms.; adults 1000 to 1,500 grms.). Shortly after the infusion there is a marked improvement in the pulse-rate; in very grave cases there will be a gradual relapse after a few hours, which makes it necessary to repeat the dose, a second, third or fourth time. This treatment can be carried out successfully by the general practitioner minus the complicated hospital appliances in the following manner: Take an ordinary clean cooking vessel (tea-kettle) boil the water 10 to 15 minutes at the end of which time the given amount of table-salt is added, (1 heaping teaspoonful to 1 litre of water) allowing it to cool to the proper temperature the vessel is placed at the required height to act as the reservoir for a syphon, one end of a long piece of tubing is placed into the solution and fastened securely; the other armed with the canula for insertion under the skin.

The injection is given preferably in the soft parts, directing the point of the canula toward the median line of the body and parallel to the integument. During the injection the canula is forced slowly along, in order to permit a greater distribution of the fluid and prevent a reflex. The lump which forms is rubbed vigorously with the one hand, while the other holds the canula. Large quantities should be divided and infused in separate places. The puncture is at once closed with adhesive plaster. Neuman warmly recommends this method based on satisfactory personal experience.

*Translated for MEDICAL AND SURGICAL REPORTER.

A CURIOUS INJURY BY A STROKE OF LIGHTNING.

There is an account in the *Archives of Otology* for January of a case in which a man was struck by lightning on the left side of the head. It passed down the ear and along the neck and breast to the right arm, where it burned through the flesh, leaving the bone exposed, and then passed out into the metal work of the buggy in which he was seated. Some days afterward he applied to Dr. Clark for relief from an otorrhœa which had supervened, when it was found that the external ear and the meatus were burned superficially and the tympanic membrane ruptured, either by the direct stroke of lightning or by the cauterization of the surface of the meatus, followed by suppuration which afterward penetrated the middle car. From the history and the appearances present the former hypothesis was considered the more probable.

AN EXTREME CASE OF SUSPENDED ANIMATION FROM CHLOROFORM RESUSCITATED BY DIRECT-INSUFFLATION IN THE INVERTED POSITION.

By A. E. PRINCE, M. D., Ph. D.,

CONSULTING OCULIST FOR WABASH RAILWAY, ILLINOIS STATE INSTITUTION FOR DEAF AND DUMB, ILLINOIS STATE INSTITUTION FOR THE BLIND, ETC.,

On July 22, 1892, chloroform was administered to Mr. John P—-, aged twenty-eight, for the purpose of opening the mastoid cells for a supposed abscess. The gentleman had a heart murmur, but it was believed that the administration would be unattended by especial danger, particularly as he had, within a few weeks, taken chloroform for another operation. No difficulty was at first experienced. Anæsthesia was rendered complete, and the operation was begun, but in a short time circulation and respiration were suspended, and the patient became livid.

The function of which organ failed first is not known, but, from the fact that there was no pulsation at the moment of the discovery of the arrest of breathing, and that the dark color followed so quickly it is presumed that the case was one of heart failure; which is also rendered probable by the existence of heart lesion, which was recognized.

No time was lost in temporizing, but resort was had at once to the inverted position. The man was suspended by the flexed knees from my shoulders, and subjected to a trotting motion around the operating-room. A description of this procedure will be found in the "Transactions of the Illinois State Medical Society 1890," and in the New York *Medical Journal*, August 22, 1891.

This inverted position, with a jolting motion, was continued while my strength lasted, after which I stood still, and my assistant practiced the Sylvester method, the body being still inverted and suspended from my shoulders. No response followed, and he was placed on the table; to all appearances he was dead. The skin was blue; a hasty ausculation revealed no signs of pulsation. Hæmorrhage had ceased, the last blood being of a very dark color. No time was lost, but the patient was again lifted to the shoulders of my assistant by whom he was trotted around the room for about one minute. At this juncture the account of the infant resuscitation by blowing directly into the mouth, published by Dr. W. E. Forest, in the *Medical Record* of April 9, 1892, entered my mind, and I called a halt, knelt down, took a deep inspiration, joined my mouth with that of the patient, and emptied the contents of my lungs into his.

The chest expanded, and the diaphragm, with the weight of the intestines, was raised, and I doubt not but that the flaccid heart was emptied of its passive blood.

Immediately the weight of the intestines and the elasticity of the chest forced a complete expiration. This was followed by another and another, until I could see that the lividity of the lids was less, though the ashen hue of the countenance persisted. A moment was taken to auscult the heart but no sound was discerned. The artificial expansion of the lungs was resumed, and continued for about three minutes, and we noted with gratification that the color of the lips continued to improve.

An interval was allowed for auscultation, but no effort at natural pulsation or respiration was detected. Again the inflation was resumed, and continued at the rate of about twelve in the minute, for about two minutes, when the gratification was enjoyed of hearing the first natural effort at respiration.

After a little time the patient was placed on a table, and the operation finished under ether anæsthesia.

This is the sixth case of suspended functions which did not respond to either the Marshall-Hall method or the Sylvester method, the first five of which recovered I under suspension treatment. Without this, am convinced all of these would have been lost. The foregoing is the only one that did not respond to the suspension method, and I am under unutterable obligations to Dr. Forest for paving the way to the employment of the direct inflation in the inverted position of the body.—*Med. Record.*

NOTES ON EPISTAXIS.

By J. K. HAMILTON, M. D. DUB., F. R. C. S. I.

In an elaborate article, in the *Practitioner*, Aug. '92, Dr. Hamilton sets forth the frequency with which physicians meet cases of severe hæmorrhage from the nose. He condemns the routine practice of plugging the nostrils, before a thorough examination is made and other means tried. He states that the source of hæmorrhage is from the septum in a large percentage of cases. The turbinated bones are not so prone to hæmorrhage.

The cause of bleeding in a majority of cases, is either traumatism, an erosion or an ulcerative process. Spurs or ecchondroses, are often found growing from the septum. The apex becoming the seat of dry incrustations, causes a breach of continuity, from which bleeding is apt to occur.

Hæmorrhage, is more frequently arterial, than venous, as it more often occurs, following the removal of ecchondroses, or exostosis. As to the best methods of dealing with hæmorrhage, the doctor, urges first a thorough examination, and unless the bleeding is very profuse or the surface from which it comes is very large, he recommends the *galvano-cautery point*, which application should be thoroughly made. He has found this method most effective.

In the use of cocaine for performing small operations, there is a liability of hæmorrhage following, after the effects of the drug have passed off.

Irrigations with hot water, to which iodine has been added, in the proportion of 1 to 10,000, are very useful. Iodine besides being slightly an antiseptic, is an hæmostatic.

Peroxide of hydrogen, a solution of antipyrin and acito-tartrate of aluminum, are also useful in controlling hæmorrhage.

The use of perchloricle of iron is condemned. If these measures fail he resorts to plugging the nostrils, iodoform gauze being the best material, and a small soft rubber catheter the best instrument for placing it. If one nostril is plugged too tightly bleeding may occur from the other.

THE RELATIONS OF PELVIC DISEASE TO PSYCHICAL DISTURBANCES IN WOMAN.

Dr. George H. Rohè read before the Amer. Ass'n of Obstet. and Gynecol. a paper upon this subject.

The author pointed out the frequency with which bodily conditions influenced mental states. Thus a torpid condition of the intestines, Bright's disease, putrefactive processes in the intestinal canal, etc., might give rise to melancholia and other disorders of the mental functions. It is not irrational to suppose likewise that diseases of the female sexual apparatus would have a not inconsiderable influence in the production or perpetuation of mental disorders. As a contribution to the knowledge of the subject the following report was submitted:

In a hospital containing 200 insane women, thirty-five were subjected to vaginal examination and twenty-six found with evidences of pelvic diseases. In eighteen of these the uterine appendages were removed with the following results:

Sixteen recovered from the operation and two died. Of the sixteen recovered, three have been discharged from the hospital completely restored, both physically and mentally. In ten, considerable improvement followed the operation in both physical and mental conditions, and in three the operation was of too recent a date to allow any definite expression of opinion.

The mental disorder present in the eighteen cases was melancholia in six cases, simple mania in one, puerperal mania in four, hysterical mania in one, and epilepsy with mania in three.

The author basing his opinion upon his experience, concludes as follows:

"The facts recorded demonstrate first; that there is a fruitful field for gynecological work among insane women; second, that this work is as practicable and can be pursued with as much success in an insane hospital as elsewhere; and third, that the results obtained not only encourage us to continue in the work, but require us, in the name of science and humanity to give to an insane woman the same chance of relief from disease of the ovaries and uterus that a sane woman has."

Selected Formulæ.

THE KEELEY CURE.

Dr. Keeley has taken great pains to keep his remedies a secret, but they have been secured and analyzed by competent chemists, and are now well known. The treatment consists in the use hypodermically. four times a day of a solution which shows an analysis of:

℞
Strychnia sulph.....gr. ½.
Atropia.....gr. ¼.
Acid boracic.....gr. xv.
Aq. dest.....oz. iv.

The formula of the tonic taken by the mouth is:

℞
Ammon muriate.....gr. j.
Aloin.....gr. ij.
Tr. cinch. comp.....oz. iij.
Aq. dest.....oz. j.
M. S. Teaspoonful every two hours while awake.

During the initial treatment—for the first one, two or three days—much heavier injections of atropia are given, in combination with morphine. Any physician will know at a glance that the quantity of strychnine used is so minute, considering its relative potency, that it can have little effect in modifying the action of the atropia. The tonics support, to a degree, but they, too, have little influence in controling the symptoms produced by that powerful drug.—*Times and Register.*

THE TREATMENT OF LUPUS OF THE NASAL MUCOUS MEMBRANE.

Cozzilino (*Rivista Italiana di Terapia e Igiene*; *Le Bulletin Médical*, No. 101, 1891) has tried with success the following treatment of lupus of the nasal mucous membrane. After twelve to fifteen applications of the galvano-cautery, which suffice to destroy the exuberant granulations of the ulcerous membrane, he employs the following formulæ to hasten the repair of the tissues:

1. Nasal douche morning and evening of tepid water to which has been added a teaspoonful of the following mixture:

℞
Rectified alcohol.....gms. 200.
Naphthol.....gms. 10.
Menthol.....dgms. 5.
Thymic acid.....gms. 2.

2. After the douche, every three or four days, apply the following solution upon a tampon:

℞
Distilled water.....gms. 50.
Trichloracetic acid.....gms. 6.

3. During the days when this solution is not applied the following is used, night and morning:

℞
Camphorated naphthol.....gms. 20.
Pure carbolic acid.....dgms. 5.
Glycerine.....gms. 25.

4. If there form yellowish, dense crusts, which are characteristic of this affection, then instead of detaching them at once they may be softened by the application of the following salve:

℞
Vaseline.....gms. 40.
Aristol.....gms. 3.
Mercurialized iodol.....dgms. 3.

5. During the day the following powder may be insufflated ten or twelve times through the nose:

℞
Aristol.....gms. 3.
Pulverized naphthol.....dgms. 5.
Boric acid.....gms. 10.
Resorcin.....gms. 2.

LEUCORRHŒA.

℞
Iron oxide, brown ("sub-carb.") } of each, 0.10 gm.
Powdered columbo } of each, 0.10 gm.
Powdered cinnamon } of each, 0.10 gm.
Powdered ergot.....0.25 gram.
One or two such powders daily.

—*Paillard.*

PILLS.

℞
Ergot extract.....1.5 grams.
Iron sulphate } of each, 4 "
Potassium carbon } of each, 4 "
Glycyrrhiza extract } of each, a sufficient quantity.
Powdered glycyrrhiza } of each, a sufficient quantity.
Divide into 50 pills. Two or three every morning, noon, and evening.

—*Braun.*

CACHETS.

℞
Calcium sulphide.....1 gram.
Dispense in 10 cachets. One, mornings and evenings.

For little girls Bouchert recommends frequent lotions of lead-water or decoction of marshmallow leaves, and the injection of a 1:3000 solution of corrosive sublimate.—*Mortimer*—*Wilson.*

CREOLIN-PEARSON IN DIPHTHERIA.

PAINT.

℞
Creolin-Pearson.....1-2 parts.
Water.....100 "
Externally!

The parts which are the seat of the false membranes, are wiped three times daily with a pledget of cotton saturated with this solution. At the same time, compresses of iced water or ice are constantly applied to the throat externally. Under the influence of this treatment, combined with a stimulant [wine, cognac], the author claims the false membranes and fever disappear in three days.

Medical and Surgical Reporter

ISSUED EVERY SATURDAY

EDITORIAL AND BUSINESS OFFICES:

29-35 N. Tenth St., Cor. Filbert, Philadelphia.

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, OCTOBER 8TH, 1892.

INOCULATION AGAINST CHOLERA.

Scientists have succeeded so far in their experiments with animals that they now consider themselves justified in experimenting upon men, to render them immune against Asiatic cholera. About two months or more ago, several persons were inoculated at Paris and the experiment created some considerable interest in scientific circles, while quite recently a *Herald* correspondent, Mr. Stanhope, has brought the matter to more general notice by undergoing the inoculation and then exposing himself to the disease in Hamburg. The papers—especially the *New York Herald*—have considerable to say about the matter just at present, but their communications really have very little scientific value, and although Mr. Stanhope has lived through the cholera epidemic, his case, while of very great interest, must not be looked upon as a demonstration of the efficacy of the preventive treatment.

Mr. Stanhope is certainly not the only person in Hamburg who exposed himself to the dangers of infection, and the only thing which he has proven is that cholera did not make way with him. Although he courted danger in every way possible, *we have no way of knowing that he has actually been infected by cholera and that the infection has been rendered harmless by the preventive treatment.* Mr. Stanhope could have carried out his experiment in Paris just as well as in Hamburg, by simply drinking a few pure cultures of the spirillum which causes the disease. Had he done that, and lived through it, we should know at least that he had infected himself with the parasites! But even this would have been no positive proof of the success of the inoculation, unless the experiment of drinking cholera cultures was repeated several times, for there is at least one case on record where a man swallowed the germs purposely and yet did not take the disease! This method, however, would hardly satisfy the *Herald*, for it would have furnished but one or two pages of material, at the most (with possibly an obituary notice a few days afterwards), while the present mode of experimentation furnishes many pages of printing matter.

We do not wish it understood for an instant, that the MEDICAL AND SURGICAL REPORTER is casting any slurs upon Mr. Stanhope or his enterprise, but we do wish most decidedly to warn our readers not to place too much confidence in this dare-devil (rather than scientific) experiment and not to expect too great results from preventive inoculations against cholera until the experiments are conducted in a

strictly scientific manner. In a word, we have the greatest respect for Mr. Stanhope's bravery, but we have not very much confidence in the value of his experiment, because, as we stated above, although we know that he underwent preventive treatment and exposure, we have no positive proof that the cholera germs have actually gained access to his intestines.

Periscope.

THERAPEUTICS.

THE ACTION OF ANTIPYRIN ON THE BACILLUS OF DIPHTHERIA.

M. Vianna, of Bahia, in Brazil, has been investigating the action of antipyrin upon Loffler's bacillus, and finds that it has marked bactericidal powers upon the pathogenic organism of diphtheria, and also that it destroys the toxic properties possessed by the products of that microbe.

His results are published in *Le Bulletin Médical*, March 30th, 1892. In his first series of experiments, M. Vianna found that in the proportion of 2½ per cent. antipyrin prevents the development of the bacillus of diphtheria in the various culture media in which it will usually grow. More than this, the addition of antipyrin to the tubes containing Löffler's bacilli in full growth killed them in less than forty-eight hours. The same result is attained in twenty-four hours, when the proportion of antipyrin is raised to 5 per cent. If the same proportions of the drug as those given above are added to the bouillon filtered from the bacillus, which will contain the toxic substances (which have been so fully investigated by Dr. Sidney Martin and described by him in the Goulstonian Lectures) elaborated by it, it may be proved that the poisonous products of the micro-organisms lose in part these toxic properties. For instance, guinea-pigs were inoculated with the filtered bouillon from cultures of the bacillus of diphtheria, and all died in less than three days; whilst if from 4 to 8 per cent. of antipyrin were added, the animals lived from five to twenty-four days, thus showing that although the drug did not render the inoculation harmless, yet its toxicity was considerably diminished.—*Lancet.*

SULPHONAL POISONING.

Koeber (*Cetralbl. f.klin. Med.*, March 12th, 1892) relates the following case. A man, aged 52, became very melancholic in consequence of increasing deafness, and more particularly of tinnitus. The sleeplessness was treated by bromide salts, and sulphonal. The latter was given in doses of 0.5 to 1.5 g. (the larger dose rarely) and continued during four to five weeks. After a temporary improvement repeated vomiting or, abdominal pain referred to the navel, and obstinate constipation supervened. A change in the urine was also noted. The daily quantity was under 1 litre. It was Burgundy red to reddish black in color, and contained at first no albumen and never any sugar. It did not give exactly the tests for hæmoglobin. Heller's reaction was absent. The specific gravity was 1021. The coloring matter was partly thrown down by alcohol. The crystals thus obtained were soluble in water, not in ether and chloroform. The chloride salt was taken up by amyl alcohol with coloration. Lead oxide precipitated and took up the coloring matter, when treated with acetic acid and common salt hæmin crystals were obtained. No sulphonal was present. The sulphonal was omitted but the color of the urine deepened, albumen, and formed elements—leucocytes, casts, but no red cells being found. Then retention of urine supervened, and later death. It would appear that the sulphonal was stored away somewhere in the body, possibly in the liver. The absence of albumen at first would apparently prove that the excretion of hæmoglobin could produce a true renal inflammation.—*Brit. Med. Jour.*

COCAINE.

M. Bignon(*Bull. de Thérap.*) formulates the results of his experimental researches as follows: (1) Cocaine parts with its valuable anæsthetic properties in a decidedly acid solution. (2)In such solutions its power as an anæsthetic is not destroyed, but becomes latent. (3) The anæsthetic property is fully restored by simply neutralizing the acid. (4) All the mineral and organic acids used in the experiments operated in the above manner. (5) The anæsthetic energy of cocaine attains its maximum when, all its acid having been neutralized, the alkaloid is held in sus-

pension by a slightly alkaline liquid. This preparation the author calls milk of cocaine. (6) Milk of cocaine is obtained by precipitating the hydrochlorate or other salt of cocaine by a slight excess of carbonate of soda. The bicarbonate does not act so well. (7) Most of the cocaine salts, especially the hydrochlorate, retain an appreciable quantity of acid; hence their solutions do not possess the full anæsthetic potency of the alkaloid; i.e., a portion of the same remains latent. (8) The anæsthetic power of cocaine salts varies greatly in different cases. Some crystallized hydrochlorates, though perfectly pure, are so acid that 10 centigrams, simply dissolved in water, are no more efficacious than half the quantity when neutralized and made into milk of cocaine. (9) The surgeon's first care, therefore, before using a solution of any cocaine salt, should be to assure himself of its neutrality; this can only be obtained at a sacrifice of limpidity; it is accompanied by some degree of opalescence. (10) The difference in the quantities required for production of anæsthesia is in most cases explainable by the difference in the acidity of the solutions employed. (11) The effect of subcutaneous injections of milk of cocaine on the human subject has yet to be ascertained. Experiments on dogs have given encouraging results in this direction, but the author has not succeeded so far in localizing the action. Milk of cocaine should always be prepared extemporaneously; as by keeping, the alkaloid is thrown down from the solutions, and much of their efficacy is lost.

MEDICINE.

DIABETES MELLITUS EXCITED BY FRIGHT.

The onset of acute glycosuria after mental trouble has recently been commented upon, severe emotional disturbances in some cases being looked upon as the cause of sugar excretion. The following case, related by Teschemacher, is an illustration of this point. The patient was a delicate boy, seven years of age, who had gone through an attack of measles some months previously. Convalescence was very slow; and on account of nocturnal incontinence the urine was examined and found to contain 4 per cent. of sugar. The child was hereditarily predisposed to diabetes, an aunt having died in early life of the disease. Some months later the patient was sent to Neuenahr. The quantity of of sugar then present was 1.9 per cent, but after eight days of treatment with restricted diet it fell to .35 per cent. Bread was then allowed, and in a further period of eight days the sugar had entirely disappeared, and it was likewise absent some days later. Milk was then added to the diet. On the following day the mother sent the boy, who hitherto had not been allowed out of sight, to the post with a letter. On the way he was attacked by a dog, which sprang at him, and he fell to the ground, where he lay half unconscious with terror. He was carried home and put to bed. Trembling at first and speechless, he lay in bed for some hours before he partook of food, while he repeatedly asked for drink. Next day he was brought to Teschemacher, who examined the urine and was astonished to find 3.3 per cent. of sugar. According to the mother, the quantity of urine passed was increased. Restricted diet was again ordered. On the following day the sugar stood at 2.4 per cent.; two days later at only .15 per cent.; and at the end of eight days it had completely disappeared. This case furnishes a striking example of the relapse of glycosuria after great mental excitement. Dietetic errors were strongly denied by the mother, and the ingestion of milk once in measured quantity could not have led to it, as the amount of sugar passed was greatly in excess of lactose in the milk. —*Bérlin. Klin Wochenschr.*, No. 2, 1892.

ASSOCIATED SPASM OF THE SUPERIOR RECTI MUSCLES.

Dr. Reich, of Tiflis, records the following case (*Vestnik Ophthalmologii*). On the 8th of March 1890, a man of thirty years presented himself with the complaint that for ten days his eyes closed and turned upward involuntarily about every ten minutes—sometimes even oftener. He was consequently unable to go about without assistance, and could see nothing during the three or four minutes the spasm lasted. He was otherwise healthy, with light eyes, and moderately dilated pupils. Reich had soon an opportunity of seeing the condition described by the patient, and found both eyes so forcibly moved upward that the pupils, notwithstanding a slight simultaneous raising of the lids, were

hidden from view. The eyes did not remain fixed and motionless in that position, but underwent nystagmic movements, the excursion of which, though varying, was never great. During the course of forty minutes three such attacks, each lasting four to five minutes, were observed. In the intervals the position of the eyes was normal. All that could otherwise be made out was pretty marked drowsiness, and a somewhat slow action of the heart. As to the cause, he had had three days' fever just before the attacks began; there was no history of any blow or any headaches. He did not drink to excess. The treatment adopted was rest with thirty grains of iodide, and an equal amount of bromide of potassium in the twenty-four hours. In a few days the attacks after getting gradually less frequent, stopped altogether.—*Amer. Jour. Med. Sci.*

ALEURONAT AS A FOOD IN DIABETES.

Ebstein (*Deut. med. Woch.*, May 12th, 1892) says that an exclusive animal diet of meat and fat is only possible for a short time, and then bread in as small quantity as possible has to be allowed in addition. The bread recommended for diabetics, whether made from animal or vegetable albumen, has hitherto been found an unsatisfactory substitute for ordinary bread. Even gluten bread has gradually come to be less used, especially in Germany, and a small quantity of ordinary bread up to 100 g. is allowed in preference. Hundhausen was the first to introduce the vegetable albumen known as aleuronat, and prepared from wheat. It is a dry powder, yellow in color, and without taste or smell. It never contains less than 80 per cent. of nitrogenous matters, nor more than 7 per cent. of carbo-hydrates. It may be used in the place of flour for making soups, sauces, etc. Bread made with aleuronat has been recommended, but the quantity of aleuronat present was at best but moderate in amount. The author has, however, succeeded in making a very satisfactory bread with it, which contains in the dry substance 66 per cent. of nitrogenous matters. Thus a diabetic, in taking half a pound of aleuronat bread containing in the dry substance even 50 per cent. of nitrogenous matters, gets 80 g. of vegetable albumen and only 72 g. of carbo-hydrates. Thus he can obtain a comparatively large quantity of the needful albumen from vegetable albumen in the same way as individuals in health. The author says that he has found aleuronat very useful in actual practice.—*Brit. Med. Jour.*

EPILEPSIA PROCURSIVA.

John Ferguson, M. D., (*N. Y. Med. Jour.*, Sept. 5, 1891.) regards this form of epilepsy especially interesting from a medico-legal point of view, as many persons who are now genuine epileptics have suffered from irregular symptoms before their disease declared itself, and others have only these premonitory conditions at the time when criminal acts were perpetrated. He divides this variety of epilepsy into three groups: 1. Those cases where the procursion constitutes the entire attack. 2. Cases where the procursion immediately precedes an ordinary attack af epilepsy. 3. Where the procursion follows an epileptic attack. In a case recorded by the author, the patient, a child, fell out of a high chair when two years old, and had immediately after vomiting and vertigo. A month later he would suddenly stare, flush in the face, rush forward, and then stand with a fixed look. When the attack passed by he would move about as usual. These continued for over a year, when the ordinary epileptic seizures developed. A female patient, age twenty-four, only had attacks when at the table. The face would become pale and then flushed, and the eyes staring. She would rush away from the table, stand still, sit down, or quietly return. No cause could be found. She was unconscious of these acts. At no time was she ever known to have a regular epileptic paroxysm. A third case was that of a man age forty-five, who had undergone a great deal of fatigue, exposure, and excitement. The most characteristic feature was the length of individual attacks. He would pass into the status epilepticus, and in this condition run straight ahead, stand still, then rush on again and again stand. He would sometimes do this for two hours, and then go to sleep. Ordinary epilepsy after a time followed. Another patient began to exhibit spells of absent-mindedness at the age of seven years. Three years later he was noticed to make short runs, of which he had no knowledge when questioned, and at the age of fifteen regular epilepsy

came on. At this time he would perform the run after the epileptic attack. Dr. Ferguson belives that to begin early and well is the real key to success in the treatment of epilepsy, and urges that the closest attention be given to all cases of absent-mindedness and momentary loss of consciousness.

MYELIN NERVE FIBERS IN DEMENTIA.

Dr. Targowla concludes (*Jour. de Med. de Paris*, Oct. 25th, 1891) that in all layers of the gray substance, myelin nerve fibers exist in a transverse direction, whose exact topography has not been pointed out. These disappear more or less completely in all dementias, whether paretic or not. The anterior cerebral lobes are most affected. The relations of this lesion to those of the vessels, nerve cells, neuroglia and meninges, has not been determinded.

DISSEMINATED SCLEROSIS DURING CONVALESCENCE FROM VARIOLA.

Sottas (*Gaz. d. Hôp.*, April 12th, 1892) records the case of a youth, aged 18 years, who contracted variola in June of last year. The rash was discrete, but the nervous symptoms were so severe as to lead to the supposition that he was the subject of meningitis. He became semi-comatose and paralyzed generally; his speech was slow and dragging rather than scanning: there was slight nystagmus, without tremor of the head, and atrophy of the muscles of the trunk and limbs, with great diminution of muscular power. In fact, at this time the paralytic symptoms were dominant, but they disappeared little by little, and gave place to contracture. The reflexes became exaggerated, and there was inco-ordination of voluntary movement, with the characteristic tremors. At the end of February, 1892, he presented the typical picture of disseminated sclerosis. The sphincters were normal, and common sensibility, the special senses and muscular sense were preserved. There were no trophic troubles of the skin. Intelligence was diminished ; he was excitable, impatient, and subject to violent fits of rage without much cause. The author looks on the case as a typical example of disseminated sclerosis of infectious origin.—*Brit. Med. Jour.*

HYPERTROPHY AND DILATATION OF THE HEART IN ADOLESCENCE OR CARDIAC ECSTASIS OF GROWTH.

Blache (*Mal. de l' Enf.*, Paris, 1891, 529.) writes that the principal cause of these cardiac dilatations may be considered the early development of the heart opposed to the late or insufficient development of the walls of the thorax. The treatment should respond to these indications and should moderate the over-activity of the cardiac movements and favor the increase of the capacity of the thorax. As special treatment of the heart the use of digitalis, with or without the addition of iron, of caffeine and particularly the tincture of convallaria are recommended. The tincture of convallaria may be used alone or associated with iodide of potash. The diet should be tonic and such as to rebuild the patient. Wise gymnastics, appropriate to the age and the nature of the conditions, aid in the general development of the patient. Frictions of the skin, either dry or with alcohol, by the aid of a woolen glove, have been used with good results, and are to be preferred to hydro-therapy. During the gymnastic lessons massage of the trunk, of the chest and limbs, is to be employed both to exercise the functions of the muscles and te moderate the gymnastic exercises. Specially to be recommended are certain respiratory gymnastic exercises, which give the best results in developing the thorax and enlarging the chest.

ON ASSOCIATED AND SUBSTITUTE MOVEMENTS IN THE PARALYZED.

Prof. Senator considers this subject in connection with a case. He divides them into three groups. Group (1) includes movements in non-paralyzed muscles, with, or instead of, an intended movement. Group (2) includes movements of similar nature in paralyzed muscles. In group (3) the original movement and its substitute or associated movements has been variously explained. Transference of reflexes, overflow of normal impulse, increased excitability, loss of inhibitory power, and an insufficient decussation of the pyramidal tracts, have all been invoked to explain these phenomena. The cause may be situated altogether outside of the central nervous organs, as in S.'s case, which is the first of the kind on record. A. R., now 53 years old, received a compound fracture of the skull twelve years ago. A

year later he became hemiplegic on the right side with aphasia. The hemiplegia and aphasia improved spontaneously to a considerable degree. After the fracture, he claims to have always experienced pain at the angle of the jaw on the right side and upon swallowing. The tongue deviates strongly to the right. In rest, the arm is lightly flexed and held to the side in pronation, the fingers flexed, the index finger over the flexed thumb. Excitement and irritation bring on choreic movements. Otherwise he presented the usual picture of an old hemiplegic. On protruding the tongue, either actively or passively, whether forcibly or gently, the paralyzed arm becomes flexed, the index finger extended, the other clenched, while the hand is raised to a level with the ear as in a military salute. The same movements were produced by pressure along the painful area at the angle of the jaw and along the anterior edge of the upper third of the sterno-mastoid muscle. Senator believes this to be due to an inflammatory infiltration around the nerves of the cervical plexus extending up to the root of the tongue. The spot is too high up to belong to the brachial plexus. He believes that the movement is reflex and not due to direct irritation.—*Berlin, Klin. Wochensch*, No. 132, 1892.

BENIGN ULCERS OF THE PHARYNX.

Dr. T. Heryng, of Warsaw, under the name "angina ulcerosa benigna," understands a hitherto-undescribed disease, which is characterized by the appearance of ulceration, generally simple, on the arcus anterior in the vicinity of the tonsils, with sharp edges and without inflammatory margin with a somewhat excavated base, covered with a grayish-white exudation which cannot be rubbed off. The length of the ulcerations is about 1 centimetre ($\frac{2}{5}$ inch), the breadth 6 to 8 centimetres ($2\frac{2}{5}$ to $3\frac{1}{5}$ inches). It does not bleed when touched, and is not very painful. After two or three days this ulceration takes on a healthy action, and after ten to twelve days it heals completely without leaving any scar. Slight general reaction of the organism always accompanies this disease, which resembles most the so-called "angina aphtosa" of B. Fraenkel. The bacteriological examination of the exudation of these ulcerations revealed the presence of two varieties of bacteria,—*streptococcus monomorphus* and *variegatus*,—but as further investigation proved, only the first was constant. The author has observed ten cases of this disease, and in two cases bacteriological examinations were made.—*Gazeta Lekarska*, Nos. 7 and 8, 1892.

SURGERY.

CATHETERIZATION OF THE BILIARY DUCTS.

Terrier and Daily (*Rev. de Chir.*, February, 1892) give the following summary of their anatomical and clinical experiences concerning the feasibility of passing a probe from the gall-bladder along the cystic and common bile ducts: (1) As a rule catheterization of the biliary passages seems to be attended with less difficulty in pathological cases particularly when these passages are dilated in consequence of retention of bile in the cystic duct. (2) In many cases, however, as a result either of curvature of the cystic duct, of persistence of its valves, or of the entrance to the duct being seated on the side of the bladder and not at its hepatic extremity, catheterization is attended with much difficulty. (3) In some cases this difficulty is insurmountable, whilst in others exploration with a probe may be practised very readily. (4) It is impossible to lay down any rules for the guidance of the surgeon. All that can be done is to point out the anatomical conditions by which the results of attempts at catheterization are likely to be influenced. (5) Forcible catheterization, even when the instrument is guided by the finger applied to the under surface of the liver, does not seem to be justifiable, and is always likely to be attended with risk. The author hold that in catherization of the biliary passages silver probes should be used, as metallic instruments can be more effectually sterlized than those made of gum or rubber.—*Brit. Med. Jour.*

A NEW TREATMENT OF CONGENITAL DISLOCATION OF THE HIP-JOINT.

That indefatigable worker, Professor Lannelongue, has recently been led to study this disease, and on December 23, 1891, he announced to his colleagues of

the Société de Chirurgie the discovery of what he considers to be a rational remedy for this malady. A dozen pathological specimens in the museum of the Hospital Trosseau show clearly that the displacement is due to the absence or, at best, rudimentary development of a cotyloid cavity, a like absence of a capsule, and a rudimentary femoral head. By resecting the head of the femur the only result obtained is the subsequent shortening of the limb by interfering with the growth of the femur. Nor is the obvious indication to create a new acetabulum fulfilled by detaching a periosteal flap. Mindful of the sclerogenic properties of zinc chloride discovered by him, M. Lannelongue has utilized his method as a means of raising a ridge of new bone round the head of the femur, and so preventing its displacement. On November 17th he performed this operation on a little girl, aged, three, the subject of this disease. The patient being under the influence of chloroform, and the limb being maintained in extension, twenty drops of a 10 per cent. solution of $Zn\ Cl_2$ were deposited by means of a syringe on the surface of the bone at eight different spots just above the femoral head. A week later a hard, osseous ring was clearly perceptible at this situation. A fortnight after the first operation a second injection of the same solution was practised, with the effect of still further accentuating the acetabular ridge. The tiny subject of this interesting experiment was presented at the meeting. The profession will await with curiosity the ultimate result of this novel essay in the field of constructive surgery.—*Lancet.*

INTESTINAL ANASTOMOSIS AND SUTURING.

Abbe, after reporting several cases of lateral intestinal anastomosis (*Medical Record*, N. Y., vol. xli., No. 14), considers the different methods for accomplishing this purpose. He objects to plates of bone, potato, or catgut, for the reason that the foreign bodies may cause obstruction, that leakage may occur, and in the case of Senn's plates, on account of the necessarily limited size, the opening in the bowel becomes, after contraction, inadequate for the performance of its function. The few extra minutes required to do the method of simple suturing does not add any complication to the case while the security against leakage and blocking is of great value.

The author had the opportunity of making an autopsy on three cases in which he had performed lateral anastomosis. In the first case Senn's plate had been used. The patient died six months after operation. The aperture made in the bowel at the time of operation was one and one-half inches in length. It had contracted to three-fourths of an inch, and was inefficient, except when laxatives were employed constantly. In the second case, the patient had died six months after anastomosis with catgut rings. The opening had contracted from one inch and a half to half an inch. In the third case, eight months after lateral anastomosis of the sigmoid by suturing, the aperture had contracted from three inches to one and one-half inches. This was perfectly competent to perform its functional work.

It is believed that the future utility of lateral anastomosis depends upon openings four inches in length in the sides of the adjacent bowel. This is almost impossible with bone plates, and only to be carried out with very long catgut rings or vegetable plates, and with less security and as much consumption of time as by suturing. The contrast is enormous between dropping back into the abdominal cavity an accurately sutured, absolutely tight and flexible, anastomosed intestine to any position in the cavity which its surroundings demand, and the returning of a huge bunch of bowel, inside of which there is a pair of five-inch plates of bone or raw potato, to remain as irritating foreign bodies stimulating peristalis and tugging at the wound until they are sufficiently softened to be carried away.

It is recommended, in cases of great fecal accumulations to first establish an artificial anus and allow some days for recuperation, when the anastomosis may be performed.

The technique of simple suturing is thus described: "Bring the two surfaces that it is proposed to unite well up in the wound and surround them by small compresses of gauze, towels, or flat sponges wrung out of hot water. Have at hand half a dozen cambric needles threaded with the ordinary finest black embroidery silk that has been well boiled and kept in alcohol. Cut in lengths of not more than twenty-four inches and tie with a single knot at

the eye of the needle, with one end cut to within two inches. Apply two parallel rows of continuous Lembert sutures a quarter of an inch apart and an inch longer than the proposed cut. Leave each thread with its needle attached at the end of its row. Now open the bowel by scissors, cutting a quarter of an inch from the sutures, both rows of which are to remain on one side of the cut. Make the bowel opening four inches long. Apply clamps temporarily to several bleeding-points, pinching the entire cut edge without hesitation. Apply no ligatures. Treat the apposing bowel in the same manner. The clamps remaining *in situ*, the parts are quickly rinsed with water. Another silk suture is now started at one corner of the openings and unites by a quick overhand the two cut edges lying next the first rows of sutures. The needle pierces both mucous and serous coats, and thus secures the bleeding vessels, from which the clamps are removed as needles reach them. This suturing is then continued round each free edge in turn, and all bleeding-points thus secured more quickly than by ligature. The serous surfaces around these button-holes are then rapidly secured by a continuation of the sutures first applied, the same threads being used, the one nearest the cut edge first. The united parts are again rinsed with water and dropped into place.

In conclusion, Abbe reiterates his conviction: 1. That the attempt to simplify the technique of lateral anastomosis by bone plates and other devices has not improved it. 2. That lateral anastomosis properly done is eminently the safest and best method of restoring the canal in most cases. 3. That simple and thorough suturing with a fine silk continuous suture, applied after the manner detailed, is most satisfactory. 4. That in order to allow for the inevitable tendency to stenosis, an aperture four inches long should be made. 5. That scarifying apposing surfaces is entirely unnecessary to quick and solid repair.—*Amer. Jour. Med. Sci.*

TREATMENT OF APPENDICITIS.

Dr. Senn arrives at the following conclusions:

1. All cases of catarrhal and ulcerative appendicitis should be treated by laparotomy and excision of the appendix as soon as the lesion can be recognized.

2. Excision of the appendix in cases of simple, uncomplicated appendicitis is one of the easiest and safest of all intra-abdominal operations.

3. Excisions of the appendix in cases of appendicitis before perforation has occurred, is both a curative and prophylactic measure.

4. The most constant and reliable symptoms indicating the existence of appendicitis are recurring pains and circumscribed tenderness in the region of the appendix.

5. All operations should be done through a straight incision; parallel to and directly over the cæcum.

6. The stump after excision of the appendix should be carefully disinfected, iodoformized and covered with peritoneum by suturing the serous surface of the cæcum on each side over it with a number of Lembert stitches.

7. The abdominal incision should be closed by two rows of sutures, the first embracing the peritoneum, and the second the remaining structures of the margins of the wound.

8. Drainage in such cases is unnecessary, and should be dispensed with.—*Medical Progress.*

TREATMENT OF SPRAINS.

Dr. N. W. Cady regards the following as an infallible remedy for sprains: A half hour's douching with water at a temperature of 120 degrees F., and the fixation of the joint by a splint on the flexor side of the joint, or upon the extensor side, if that be more convenient.—*Med. Record.*

OBSTETRICS.

MISSED ABORTION,

Three typical cases of this condition are presented to his reader (*Lancet*,) by Dr. Lewers, Obstetric Physician to the London Hospital. He says:

Cases of missed abortion are by no means uncommon; they are easily recognized if the possibility of the existence of the condition is kept in mind and proficiency has been acquired in the bimanual method of examination especially so far as

concerns the determination of the size of the uterus. Yet comparatively little prominence has been given to the subject by the majority of writers on gynæcology, with the notable exception of Dr Matthews Duncan, whose classical lecture on "Missed Abortion" first led me to recognize cases of the kind. The history is usually of great importance. In most cases the patient, having been previously regular, misses one or more periods and, especially if more than one period has been missed she probably believes herself to be pregnant. If it should happen at this time that the medical attendant is called on to make an examination, the size of the uterus as determined by him may be of much value in making the diagnosis when other symptoms arise later on. We have, then, to begin with, an interval of amenorrhœa accompanied by the other symptoms and signs of early pregnancy. Generally the first indication of there being anything unusual in the case is the occurrence of hæmorrhage, usually at first slight and intermittent, the intervals between the losses being days or weeks; or it may be that there is a constant, blood-stained discharge, the proportions of blood varying from time to time. It is usually on account of this hæmorrhage that the patient seeks advice. It is obvious how valuable a previous examination of the patient may prove, if a month or more has elapsed since the previous examination: for it may be found that the size of the uterus has remained stationary or has even somewhat diminished. It often happens, however, that we have no previous examination to guide us, and then it is best to compare the size of the uterus when the case is first seen with the size it should have been had the pregnancy been a normal one, reckoning from the beginning of the interval of amenorrhœa. The treatment depends on the amount or persistence of the hæmorrhage. In some cases bleeding is inconsiderable till pains come on leading to the spontaneous expulsion of the ovum. In other cases bleeding is often rather free from time to time, and may be continued over a long period without the uterus showing any tendency to discharge its contents. In the second case described, bleeding had lasted three months. In such cases the right treatment is to dilate the cervix and clear out the uterus.—*Md. Med. Jour.*

GYNECOLOGY.

PREGNANCY AND OVARIAN TUMOR.

Dr. Wm. Gardner (*Montreal Medical Journal*) says:

The association of pregnancy and ovarian tumor, if left to nature, is fraught with danger to the woman, whether the termination be premature or at full term. When left to nature, abortion or premature labor may occur, in either case with frequently fatal results to the mother.

When the case proceeds to labor at full term, the result to the mother may be rupture or such other injury to the tumor that fatal peritonitis carries her off.

Tapping of the tumor, while it may temporarily relieve tension, is by no means free from danger by injury to the uterus or otherwise, and it does not cure the patient.

Ovariotomy with modern precautions is nearly as safe as in the non-gravid condition of the uterus, while the woman is at once cured of a disease which must ultimately demand operation.

The second case here related shows that serious complications such as torsion of the pedicle and consequent peritonitis with adhesions, necessitating the use of the drainage tube for so long a period as five days, does not necessarily lead to abortion.

Ovariotomy in the present status of surgery, in the great majority of cases, must be the only proper treatment, and is often urgently demanded to relieve tension.

The indication for the operation in the case of small abdominal tumors is even more urgent, because of their great liability to torsion of the pedicle; and in the case of the pelvic tumors, by reason of the almost certain rupture or necrosis from compression during labor.

CONSERVATIVE TREATMENT OF TUBAL DISEASE.

At the meeting of the Academy of Medicine, says *New York Medical Journal,* Dr. Paul F. Mundé read a notable paper on the conservative treatment of salpingitis. The paper was remarkable for the clearness with which it showed the absence of justification for what the author termed the Birmingham epidemic, meaning the rage for salpingo-oophorectomy. He con-

siders it one of the draw-backs to the Listerian system that it has robbed certain mutilating and unnecessary surgical procedures of their dangers to life and consequently led to their indiscriminate and uncalled for execution.

Dr Mundé used the word conservative in the sense of preservative of the essential organs in women, and it is interesting to note that their preservation is not incompatible with a curative laparotomy, as was strikingly brought out in the discussion by Dr. Polk, who related the history of a case in which he had removed the ovary of one side and about half the ampulla of the oviduct on the other side, and yet the patient conceived.

This case is in striking contrast to the opinions of those who declare that in cases of tubal disease the organs are rendered useless, and that their removal is therefore really of no loss to the patient.—*Mèd. Mirror*, Sept, 1892.

AMENORRHŒA OF SCHOOLGIRLS.

Dr. T. A. Reamy in discussing the amenorrhœa of anæmia, common to schoolgirls, says: (1) She must leave school, and not even study at home. (2) She must spend several hours each day in the open air, either walking or riding. In winter she must, of course, be warmly clad; but must wear no sheepskins or other chest-protecting pads. Standing in the open air, she must be induced to breathe deeply with the mouth closed, this should be done for at least fifteen or twenty minutes, and be repeated at least twice a day. Nothing that can be done will more rapidly improve the character of her blood. (3) She must sponge her extremities and body each morning on arising from bed. The water must be of the temperature of the room, and she must practice friction freely with an ordinary towel. (4) She must drink plenty of milk and eat plenty of beefsteak. (5) She must take small doses of iron, combined with some bitter tonic, three times a day. Improvement may be somewhat slow, but if this course is faithfully carried out a perfect cure will result, and her education may then be finished.

If this course or its equivalent be not followed, these cases will go from bad to worse, and finally die of pulmonary tuberculosis.—*Arch. Gyn. Obs. and Ped, Canada Lancet.*

HYGIENE.

IMMUNITY PRODUCED BY MILK.

Brieger and Ehrlich (*Deut. med. Woch.*, May 5th, 1892) rendered a gravid goat immune against tetanus. Up to a certain point ascertained by the authors, immunity could be conferred on mice against inoculation with tetanus bouillon by subcutaneous injections of the milk (0.2 centigramme) from this goat. By feeding the older mice with the goat's milk, no immunity could be brought about, perhaps in part because mice do not thrive on this milk. It is indispensable to isolate these protective substances. After the separation of the casein, the whey still retained the protective powers of the milk. The authors say that they have also obtained positive results by the same method in the case of enteric fever infection.—*Brit. med. Jour.*

CATARRHAL LARYNGITIS OF BICYCLISTS.

Dr. Rayoneau (*Med. Neuigkeiten*, No. 2, 1892) describes it as follows: Acute beginning; sensation of dryness; cough, with a somewhat mucous expectoration, and now and then faint streaks of blood. The voice is changed, the mucous membrane of the throat is reddened. The writer has observed these symptoms in nine young men who rode the bicycle to excess several times a day. The mouth breathing, the rapidity and the pressure with which large quantities of air are forced into the larynx and lungs are the cause. In all cases avoiding of the cause was followed by rapid recovery.

INJURIOUS EFFECT OF THE TELEPHONE UPON HEARING.

Gellé, of Paris, observes that those who frequently use the telephone sometimes present a series of aural disturbances similar to those resulting from the continued action of loud noises. In such cases there may be found inflammation of the membrana tympani and of the tympanic cavity, or there may be irritable conditions of the nervous apparatus of the ear, exercising an influence upon the general nervous system. Hence in the cases observed, there were pains in the ear, diminished hearing, subjective noise, hyperæsthesia

acoustica, and vertigo, all of which were manifested at first during loud auditory impressions, but later became permanent, with general nervous irritability. Probably, for the production of the aforesaid disturbances, there must be a certain predisposition, due either to a greater excitability of the entire nervous system or a previous and still existing disease of the auditory organ.—*Annals des Maladies de l'Oreille*, No. 12.—*Amer. Jour. Med. Sci.*

NEWS AND MISCELLANY.

THE NEW FRENCH MEDICAL LAW.

The progress of the *projet de loi* relative to the practice of medicine in France has been so much interrupted by changes of Ministry and minor political complications that it is hardly surprising if even "official persons" (to use a favorite phrase of Carlyle's) in this country are in some perplexity as to the exact situation of affairs at present. In view of inquiries which have been addressed to us on the subject, we thought it well, in the absence of authentic official information, to apply direct to Professor Cornil, who, as a member of the French Senate and author of the elaborate report on the Bill, a summary of which was recently given in the *British Medical Journal*, is the highest authority on the subject. M. Cornil has favored us with a reply, of which the following is a translation: "The Bill as to the practice of medicine, passed by the Senate, was sent back to the Chamber of Deputies because the Senate had introduced several modifications into the text as passed by the Chamber. I hope it will soon come back to us in the Senate, unless the Chamber allows it to pass just as we sent it to them." It is at least clear from this somewhat Delphic utterance that the *projet* has not yet accomplished its final development into law. We believe, however, that the Chamber has already passed the first clause of the Bill, which is the one which chiefly concerns foreign practitioners. It may be taken for granted, therefore, that the lower grade of *officier de santé* is doomed, and that henceforth all persons wishing to practice medicine in France must possess the diploma of Doctor granted after examination before a French Medical Faculty. Exemptions from certain parts of the earlier examinations may be made in the case of foreign qualified practitioners, but in all cases the three final examinations must be passed in full.—*Brit. Med. Jour.*

HEREDITARY TRANSMISSION OF MUTILATIONS.

Upon the subject of hereditary transmission of mutilations, some interesting observations have recently been recorded by Dr. C. G. Lockwood, of New York. He says: "I selected a pair of white mice on account of their rapid breeding. I bred them in and in for ninety-six generations, as they breed every thirty days, and when they are thirty days old they are able to reproduce themselves. I destroyed all sickly and defective ones by breeding only the fittest. I bred all disease out of them and had a pure-blooded animal, larger and finer in every way than the original pair. In breeding their tails off, I selected a pair and put them in a cage by themselves, and when they had young I took the young and clipped their tails off. When old enough to breed I selected a pair from the young and bred them together; and when they had young I clipped their tails. I continued this breeding in and in clipping each generation and selecting a pair of the last young each time, in seven generations. Some of the young came without tails, until I got a perfect breed of tailless mice. I then took one with a tail and one without a tail, and bred them together, and by changing the sex each time—a male without a tail, a female with a tail, and next a female without a tail and a male with a tail—I was finally rewarded with all-tail mice." So far as they go, these experiments appear to be conclusive of the hereditary transmission of mutilations, but more evidence is greatly needed upon the subject.—*Med. Press.*

PRIZE ESSAYS.—ON THE ACTION OF ALCOHOL AND ITS VALUE IN DISEASE.

The American Medical Temperance Association, through the kindness of J. H. Kellogg, M. D., of Battle Creek, Mich., offers the following prizes:

1st. One hundred dollars for the best essay "*On the Physical Action of Alcohol, based on Original Research and Experiment.*"

2d. One hundred dollars for the best essay "*On the Non-Alcoholic Treatment of Disease.*"

These essays must be sent to the Secretary of the Committee, Dr. Crothers, Hartford, Conn., on or before May 1, 1893. They should be in type writing, with the author's name in a sealed envelope, with motto to distinguish it. The report of the committee will be announced at the annual meeting at Milwaukee, Wis., in June, 1893, and the successful essays read.

These essays will be the property of the Association and will be published at the discretion of the committee. All essays are to be scientific, aud without restriction as to length, and limited to physicians of this country.

Address all inquiries to

T. D. Crothers, M D.,
Secretary of Committee,
Hartford, Conn.

OFFICIAL CHANGES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE FOR THE FIVE WEEKS ENDED SEPTEMBER 24, 1892.

Hutton, W. H. H., Surgeon. To proceed to Cape Charles Quarantine for special duty, Aug. 27, 1892. To proceed to Sandy Hook, N. J. for special duty, Sept. 10, 1892. Relieved Sept. 16, 1892.

Hamilton, John B., Surgeon. To report in Washington, D. C.. for special temporary duty, Sept. 2, 1892.

Sawtelle, H. W., Surgeon. Detailed for special duty as quarantine inspector Canadian frontier, Sept. 5, 1892. To proceed to Sandy Hook, N. J., for special duty, Sept. 16, 1892.

Stoner, G. W., Surgeon. Detailed for special duty as quarantine inspector Michigan ports, Sept. 3, 1892.

Meade, F. W., Surgeon. To proceed to Baltimore, Md., on special duty, Sept. 24, 1892.

Banks, C. E., Passed Asst. Surgeon. To proceed to Washington, D. C., for special duty, Aug. 26, 1892. To rejoin station Sept. 8, 1892. To proceed to Washington, D. C,, for special duty, Sept. 22, 1892.

Devan, S. C., Passed Asst. Surgeon. To proceed to Delaware Breakwater Quarantine for special duty, Aug. 28, 1892.

Kalloch, P. C., Passed Asst. Surgeon. To proceed to Portland, Me., for temporary duty Aug. 26, 1892. Detailed for special duty as quarantine inspector Maine ports, Sept. 8, 1892. To proceed to Washington, D. C., for special duty, Sept. 15, 1892. To proceed to Portland, Me., for temporary duty, Sept. 22, 1892.

Wasdin, Eugene, Passed Asst. Surgeon. To proceed to Sandy Hook, N. J., for special duty, Sept. 13, 1892.

White, J. H., Passed Asst. Surgeon. To proceed to Way Cross, Ga., for special duty, Sept. 19, 1892.

Kinyoun, J. J., Passed Asst. Surgeon. To proceed to Baltimore, Md., on special duty, Aug. 27, 1892. To proceed to Philadelphia, Pa., on special duty, Sept. 1892. To proceed to New York, N. Y., on special duty, Sept. 21, 1892.

Cobb, J. O., Passed Asst. Surgeon. To proceed to Sandy Hook, N. J., for special duty, Sept. 19, 1892.

Stoner, J. B., Passed Asst. Surgeon. To proceed to Sandy Hook, N. J., for special duty, September 13, 1892.

Wertenbaker, C. P., Passed Asst. Surgeon. To rejoin station (Chicago,) Aug. 28, 1892.

Perry, J. C., Asst. Surgeon. To proceed to Norfolk, Va., for temporary duty, Aug. 27, 1892. To proceed to Cape Charles Quarantine for special duty, Sept. 8, 1892.

Simpson, W. G., Asst. Surgeon. To proceed to Delaware Breakwater Quarantine for special duty, Sept. 2, 1892.

Rosenau, M. J., Asst, Surgeon. To proceed to Cape Charles Quarantine for special duty, Sept. 10, 1892.

Cofer, L. E., Asst. Surgeon. Granted leave of absence for sixty days on account of sickness, Sept. 2, 1892.

Stewart. W. J. S., Asst. Surgeon. To proceed to Charleston, S. C., for temporary duty, Aug. 26, 1892. To rejoin station (New York,) September 2, 1892.

Strayer, Edgar, Asst. Surgeon. Assigned to temporary duty at Boston, Mass., Sept. 6, 1892.

PROMOTION.

Geddings, H. D., Commissioned as Passed Assistant Surgeon, Sept. 2, 1892.

Wertenbaker, C. P., Commissioned as Passed Assistant Surgeon, Sept. 2, 1892.

APPOINTMENT.

Strayer, Edgar, M. D., of Pennsylvania, Commissioned Assistant Surgeon, Sept. 2, 1892.

OFFICIAL CHANGES IN MEDICAL DEPARTMENT U. S. A. FROM SEPT. 25, 1892, TO OCT. 1, 1892.

Captain Edgar A. Means, Assistant Surgeon U. S. Army is relieved from further duty with the Commission appointed for the location and marking of the boundary between Mexico and the United States, and will without delay proceed from El Paso, Texas, to Fort Clark, Texas, and report in person for duty to the commanding officer of that post.

Major Robert H. White, Surgeon U. S Army, granted leave of absence for two (2) months, to take effect during October 1892.

NO OPENERS

FOR CHAMPAGNE REQUIRED.

By means of a small seal attached to wire, the latter can be broken and easily removed by hand, together with top of cap, on G. H. MUMM & CO.'S Extra Dry.

G. H. Mumm & Co. having bought immense quantities of the choicest growths of the excellent 1884, 1887 and 1889 vintages, the remarkable quality and delicious dryness of their Extra Dry can be relied upon for years to come.

"By chemical analysis the purest and most wholesome champagne."—R. Ogden Doremus, M. D., LL.D.,
Professor of Chemistry, N. Y.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{75}$ gr.), Atropiæ Sulph. ($\frac{1}{150}$ gr.), Codeia ($\frac{1}{50}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

DR. WM. A. HAMMOND'S

PRIVATE HOSPITAL

FOR

DISEASES

OF THE

NERVOUS SYSTEM

WASHINGTON, D.C.

The Hospital is situated on Columbia Heights, at the corner of Fourteenth Street and Sheridan Avenue. The position is the highest in the immediate vicinity of Washington. The soil is dry and all the surroundings are free from noxious influences. The Fourteenth street cable cars run almost to the door. The building is very large, and in its construction every sanitary requirement has been fulfilled. The number of patients is limited to twenty. Electricity in all its forms, baths, douches, massage, inhalations, nursing, etc., are provided as may be required by patients, in addition to such other medical treatment as may be deemed advisable. The building is heated throughout by steam. For further information DR. HAMMOND can be addressed at the

Clinical Lectures.

DEFORMITY OF KNEE PRODUCED BY RHEUMATOIDAL ARTHRITIS—OPEN WOUND SECTION OF TENDONS AND FORCIBLE STRAIGHTENING.*

H. AUGUSTUS WILSON, M. D.,
CLINICAL LECTURER ON ORTHOPEDIC SURGERY IN THE JEFFERSON MEDICAL COLLEGE, PROFESSOR OF ORTHOPEDIC SURGERY IN THE PHILADELPHIA POLYCLINIC.

Gentlemen:—The first case I bring before you this morning is the one I had before you at the end of our last clinic, the patient with a contraction at a right-angle of the knee joint, due as you will remember to rheumatoidal arthritis. You will also remember that I explained at that time why I did not then operate, namely, on account of the premature appearance of menstruation. On Saturday last I performed the operation, the menstruation having ceased, proceeding by vertical open incision to avoid cutting the external popliteal nerve which lies close to the biceps tendons. Through the incision the nerve stood out prominently exactly in the track of the knife, so that I could hardly have avoided cutting it had I adopted the subcutaneous method. It was directly in contact with the biceps tendon. I divided the tendon of the semi-membranosis and semi-tendinosis subcutaneously as there was not a similar danger. As soon as these contracted structures were divided considerable exertion was required to place the knee in a straight extended position. I then applied a plaster of Paris dressing from the foot to the knee and another application from the knee to the hip and when these had hardened I applied the connecting iron side bars and covered the ends of them with more of the plaster of Paris. This makes a rigid apparatus leaving a space of about four inches around the knee so as to provide for the application of the dressings. The patient has had but very little pain since. Her temperature has remained practically normal. There was at first a rise to a point near 100° which is usual after any operation; then there was almost a complete subsidence of fever. The patient will remain in the position in which she now is until the wound has healed and there are no signs of inflammation; steel braces will then be applied to maintain the position now held to prevent any yielding of the knee upon use, until a firm ankylosis takes place, when all apparatus will be dispensed with.

*Delivered at the Jefferson Medical College Hospital.

EXTENSIVE TUBERCULAR DEPOSITS—EVACUATION OF A HIP ABSCESS.

I am very desirous always to show you results, and I would far rather show you the unfortunate than the good results, because in this branch of surgery the results are not always the brilliant ones seen in other branches of surgery because of the difficulty of eradicating the cause, namely, tuberculosis. This patient has been presented to you before. The trouble began as a tubercular caries of the lumbar and dorsal vertebræ, with a secondary involvement of the hip-joint requiring an incision of the joint, and subsequently the incision of another portion of the femur, and again, by Professor Forbes, the removal of another portion of necrosed bone. With drainage applied the sinuses closed after these operations which were necessarily

incomplete because of the impossibility of removing all of the diseased bone. Unfortunately, however, this case is an example of the results of those cases where operative procedures were resorted to too late. You will remember the large sinus just above Poupart's ligament which extended into the pelvis and thence in direct communication with the hip joint. The abscess on the side of the trochanter did very nicely, but on Tuesday last I recognized fluctuation and redness extending almost to the knee-joint. I bring the case before you this morning to open this abscess and afford increased drainage. This illustrates the course many of these cases are apt to run. There is an invasion of almost every part of this child's body with the tubercle bacillus, and the disease is constantly manifesting itself in new places. The question that must arise is: What shall we do here. Amputation at the hip-joint is not justifiable, for even though I should get rid of a large portion of the tuberculous tissue I know that back of this are the diseased lumbar and dorsal vertebræ and the acetabulum is perforated giving exit to pus into the pelvis. I must therefore resort to a more conservative form of treatment and hope, for there is hope, that the child will recover. The time is past when we can say that even in so desperate a condition as this one such a case is hopeless. I shall secure drainage and endeavor to keep the parts aseptic by washing the cavity out with peroxide of hydrogen and injecting with the iodoform emulsion. Observe this long cicatrix upon the side, and note how thoroughly the wound has healed, all due to the most absolute antisepsis and asepsis. The point of incision here shall be in the median line of the thigh away from the line of the femoral artery and at the point where the fluctuation is most marked. This is a trifling operation, but it is an illustration of what must be done in these tubercular cases. Wherever pus be found, I care not what it is, whether the old fashioned "laudable pus" the existence of which is now no longer recognized, or whatever its source may be, the proper thing to do is to get rid of it by free incision, and afford drainage.

The aspirator so frequently resorted to but a few years ago is rapidly taking its deserved place in the museum of curiosities or when used at all is used for diagnosis of obscure cases.

The freedom with which exploratory incision may be made renders the use of an aspirator even for diagnostic purposes unnecessary, or at best of doubtful efficiency.

One of the principal objections to its use in the evacuation of an abcess lies in the mechanical impossibility of all the material passing through the trocar, and of the unsatisfactory manner of injection of remedial agents when it is employed.

The withdrawal of the mere fluid part only is not conducive to a closure of an abscess cavity and by its use the evacuation of the caseous portions and fibrous detritus can not be accomplished. I am not in the habit of using the aspirator even for diagnostic purposes except on very rare occasions for at the best it can only prove the presence of pus and does not indicate the origin or extent of the accumulation or the cause.

Free incision facilitates complete evacuation, the removal of the exciting cause, and the permanent closure of the cavity, and when done with aseptic precautions is not accompanied with unfavorable conditions.

Having made the incision and evacuated the pus, I shall now proceed to wash out the cavity thoroughly with peroxide of hydrogen to entirely burn out or oxidize the dead tissue that it has access to. I shall then inject a ten per cent. emulsion of iodoform to keep the parts clean and to destroy the germs. The temperature of the child will almost immediately fall one or two degrees. I am not desirous of tracing the sinus by means of a probe or my finger, for I am sure it is not far from, if not in, the hip-joint, and further removal of necrosed bone is impossible. I wish to reiterate one point of great importance, and that is, do not inject the bichloride of mercury solution first, and then the peroxide, for the bichloride of mercury coagulates the albumen and prevents rapid action of the peroxide of hydrogen. Inject the peroxide of hydrogen first, and then the bichloride if you use the latter and then follow with the emulsion of iodoform which is more effective than the powder because it fills up every cavity and renders the recovery more satisfactory. You can see the bubbling of the

peroxide of hydrogen showing that it is proceeding with its destructive work. I shall show the result of this treatment on some future occasion.

RICKETS, BOW-LEGS, KNOCK-KNEE.

I bring before you this morning a class of cases which as yet I have not shown you in this winter's course. I cannot for want of time enter into the pathology of rickets, but I want to tell you something of the subject. I wish to speak of rickets as an element in the production of deformities. This child illustrates a form of rickets that we very often see, namely, bow-legs, called also genu valgum, genu extrorsum and out-knee. Observe first the position of the legs, how they are distorted from the straight line into the position of bow-legs. There is not a deformity in the body that exists as a single deformity, and particularly does this condition of bow-legs show this. The deformity of the legs has produced a deformity of the ankles in the form of talipes valgus. The curvatures of long bones generally begin to show themselves between the ages of three and six years, and they almost invariably occur in badly-nourished children and those who have manifestations of rickets in other parts of the body. It is a most unusual thing not to have an enlargement of the epiphyses of the long bones. This enlargement is well-marked in this patient at the wrists and at the ends of other bones. I shall look for what are called "rosaries" or nodules at the juncture of the ribs with the costal cartilages, and I find them well-marked. Now notice the alteration of the axes at the knee-joints. When the legs are flexed to a right angle the thighs and legs are nearly parallel, but if I extend the leg the bowing occurs. The bowing is due in part to an unnatural obliquity of the condyles of the femur. When the head of the tibia is thrown under the posterior surface of the condyles no deformity is apparent, but the moment I bring the leg out from that position it is thrown into the deformed position. There is also a condition of bowing present which is a particular feature, but is not an essential feature, namely, an enlargement of the epiphyses of the bones. Notice now the condition of the ankle-joint. The enlargement here is marked. If I were to examine the cranium I should doubtless find some other point of view. I shall now ask you to notice the clinical phenomena in these other cases.

RACHITIC ANTERIOR BOW OF TIBIA.

On the left leg of this little girl you will observe a manifestation of a different character. There is an anterior bowing of the crest of the tibia on this side. The right leg is almost straight and natural in appearance. When the child first came to the hospital it was in a condition of very pronounced bow-leg but under proper mechanical and therapeutic treatment this has disappeared leaving only the present anterior bow of the tibia. The obliquity of the knee has entirely disappeared. This anterior bowing is one of the most unsatisfactory conditions to deal with because it is impossible to put any pressure on this crest without producing suffering and cutting through of the tissues. The sharp knife-like crest of the tibia has no covering of soft tissues except the skin and pressure upon this sufficient to be effective in correcting the curvature will inevitably produce slough, and therefore mechanical treatment is not to be considered.

KNOCK-KNEE.

Now observe another case. Here is a condition of approaching knock-knee known also by the names genu varum, genu introrsum, etc., in knee. It is only beginning, but it is therefore a proper time to prevent the progress of deformity. Notice especially the position of the left foot which is the condition that attracted the attention of the mother and caused the child to be brought here. The enlargement of the condyles is very perceptible, and the beginning deformity though not in a gross form is also very perceptible. The rosaries are to be found here also, and the enlargement of the wrists, In the sitting position the angle of the knee-joint is in the normal position, but you can see a beginning curvature extending from the knee to the ankle. The child has also a slight rachitic curvature of the spine. Also see the pendulous abdomen, which is generally found in these patients. This may be due to an accumulation of flatus, or it may be an associated phenomenon of the disease. The question now is, how are we going to prevent the curving and any increase in the curving. Your teachers who will dwell at length upon this de-

formity inducing disease will tell you that the condition depends on malnutrition, and that the bones are soft from a deficient deposition of lime salts. Then we must administer remedies which produce hardness and the deposition of salts, and, secondly, we must study the application of methods of mechanical restraint. The steel apparatus is preferable for the latter purpose, because it can be adjusted from time to time.

The joints should be placed in the position to favor the mechanical functions of normal joints with pads so arranged as to restrain all bending of the bones. At the lowest joint, the mallelous, for example, in this case of bow legs, we have a support placed, and then above the ankle midway between the ankle and knee at the point of greatest curvature there is a resistance pad and again at the knee is another. This apparatus is applied at first in a position which will do no good merely to accustom the child to wearing it. Then gradually we get it into proper position by adjusting the pressure pads to accomplish the greatest good without being unbearable. It must be kept on day and night to prevent increase of the curvature, being removed only for the necessary washing of the feet and legs and then re-applied. Now, with reference to the deposit of bone salts, various methods have been suggested, but the most satisfactory I have found is the administration of phosphorus $\frac{1}{150}$ grain in one-half teaspoonful of cod-liver oil. This constitutes the best form of treatment for the prevention of the condition and favors the deposit of salts. If it is not well borne the syrup of the iodide of iron or the syrup of hypophosphites may be used. But better still, attention must be paid to the proper nutriment for the child to take. I believe rickets is frequently caused by the use of patented farinaceous foods and when I find that such is the case I always stop that and try to imitate the mother's milk. Children of American parents rarely show rickets. Generally it is found in the children of the Portuguese, Italians and negroes, where the diet of the nursing mother is inadequate to supply proper nutritious milk for the infant. To remedy the nutrition will therefore always be the first step in the prevention of these deformities, in the prevention of their progress as well as in the correction of deformities already existing.

Communications.

AN OBSCURE CASE OF APPENDICITIS MASKED AND COMPLICATED BY OVARIAN ADHESIONS—OPERATION AND RECOVERY.

By GEORGE I. McKELWAY, M. D.,

GYNÆCOLOGIST TO THE PHILADELPHIA HOSPITAL.

Early in June of this year, Marie K., a Swede, came to me with the following history: She was twenty-four years old, single, a ward-maid in a hospital. Until three years ago she was in robust health. About then, however, she began to have excruciating pain in the right ovarian region at her menstrual periods and had, constantly, tenderness there on pressure. About two years ago she consulted a gynæcologist, who found a retroverted uterus and inserted a pessary. She could not retain this, however, because of the pain it caused her, and did not return to his care. She lost flesh, became pale and weak, and unable to work; and in this condition consulted me.

A vaginal examination showed a retroverted uterus bound down by adhesions, and an exceedingly sensitive, adherent mass, the size of a walnut, to the right of and beside the uterus. I took this to be an enlarged ovary itself bound down, and causing the binding down of the uterus, by reason either of an inflammatory condition in it, or in the tube, or both, and advised an abdominal section. To this she consented, and I sent her to the Presbyterian Hospital, where I was at the time substituting for my friend, Dr. E. L. Duer, and operated by coeliotomy on July 9th, 1892.

After getting my fingers into the peritoneal cavity, I found the uterus bound with adhesions, as I expected, and freed it. The left ovary and tube were free and normal. The right ovary, the distal end of the appendix vermiformis and the adhesions about them formed the mass I had felt through the vagina. I carefully freed the ovary and appendix, and brought them and the tube up to the abdominal wound. I carefully separated all adhesions and

found both tube and ovary apparently healthy. The ovary was considerably larger than was the left one.

Examination of the appendix showed it to be very tense, erect, curved, very long and increased in diameter to the size of a large lead pencil. I removed it, and as there seemed to be no condition of the ovary or tube justifying their excision, they were not disturbed. The abdomen was closed without irrigation or drainage and the patient made an uneventful recovery.

The removed appendix showed no perceptible evidence of leakage or rupture. It was five and three quarter inches long, and its mucus surface was highly congested. It contained no pus, but did contain two fecal concretions the size and shape of a grain of wheat. It ruptured, on handling, at about its fourth inch, at the place where the fecal concretions were.

The patient is apparently well. She has gained flesh and has menstruated twice since the operation with very little discomfort. A vaginal examination shows her uterus to be in normal position, and reveals neither the pre-existing mass nor the exquisite pain on the right side she formerly suffered when examined. She believes herself well.

The case is interesting because, as I believe, the condition of the right ovary and of the uterus was secondary to the inflammatory condition of the appendix, and furthermore, because while pain and tenderness and a tumor were made out in the ovarian region, there had never been complaint or evidence of any of the three where they are generally expected in appendicitis, i. e., about McBurney's point. There was no history of any thing like an acute attack of peritonitis or appendicitis, and the exacerbations of pain always occurred at her menstrual periods.

It is instructive because of these circumstances and further teaches the oft repeated lesson of the difficulty and, sometimes, impossibility of exact diagnosis of intra-abdominal and intra-pelvic conditions.

Another most important matter is, that despite the fact that the one ovary was enlarged, adherent, and possibly much congested because of its circulation being obstructed by these adhesions, yet her restored health and her freedom from pain up to this time justify me in not having removed it. I believe that its condition and much of her pain was occasioned by its strangulation and that the freeing of it would restore it to its normal state and relieve the patient of any pain caused by it. As I have said, events so far have borne out this theory. Is it not possible that in many more cases the freeing of adherent ovaries may, because of the rehabilitation of their circulation and so their restoration to the possibility of normal performance of function, result in much better things for the patient than their removal? It is not proven that adhesions about an ovary, healthy save for conditions caused by these adhesions, are sufficient reason for its removal and yet we constantly read of an ovary removed, apparently as a matter of course, because "enlarged" or "adherent," and infrequently its sound fellow (may be sister is the better word) is also excised because the other was.

In the operation, and in the subsequent care of the patient I was most intelligently and thoroughly assisted by Dr. J. H. Girvin, then a resident physician in the hospital, to whom my thanks are due.

WINTER COUGH AND NOSE OBSTRUCTION.

Mayo Collier says (*Lancet*) that the frequency of chronic winter cough, laryngeal catarrh and cold in the head is unfortunately, in this country, Europe and America, notorious. He has recently shown from the examination of over 1,000 living and 5,000 dried skulls that some irregularity of the nasal septum, causing more or less obstruction to nasal respirations, is a constant feature of nine out of every ten persons living in those countries. Facts are steadily accumulating, and the conviction is becoming established with many who are competent to judge "that chronic winter cough, laryngeal catarrh and post-nasal catarrh, with all their consequences, are in a majority of cases the direct result of breathing unfiltered, cold and dry air that has not passed through the proper respiratory gate." This proposition can only be refuted by the evidence to the contrary, and established by showing that every person suffering from winter cough or laryngeal catarrh or a majority of these, has some marked obstruction in the nose. This investigation is now proceeding at several centers, and it is with the object of still further directing attention to the subject that he writes.

SUCCESSFUL SURGERY.*

By F. A. DUNSMOOR, M. D.,
MINNEAPOLIS.

The great reduction in the mortality in surgical operations during the last decade is due to the adoption of the germ theory, and to the fact that there are more experts (and by expert, I mean those who know by touch, sight and location healthy or diseased tissue; when to tear and when to cut, and are competent to face any hæmorrhage; who realize what shock means, and who say *no* to the petitions for the impossible operation). We are also indebted to the better appliances of the present day, and to the greater cleanliness, which is next to Godliness—in surgery, next in advance.

It has been suggested by many that the wonderful success of Tait abroad and Price in Philadelphia impair the value of the germ theory. This reasoning is fallacious; would any practical man declare it to be unnecessary or foolish to lock the door until the night the burglar attempts an entrance? We are not all mind-readers, we *keep* the key turned that the protection may be sure. It is absolutely certain that if no germs of disease are about it is needless to use germicides in any operation.

To grow corn, corn must be planted, when nothing but corn will be produced. Pus will never appear in a wound unless there has been exposure to a pus-producing germ, but where there has been such exposure it is certain to follow as if the patient had been vaccinated.

The germicide is *per se* of no advantage to any clean wound, nature alone supplying every requisite for healing and union, and making astounding cures when allowed by non-interference. It is protection for home industry "out McKinleying McKinley." If the surgeon, assistants, dressings, sponges and patient have about them *no* contagious products it is hardly necessary to try to kill bacteria which may be miles away; but woe to him who relies on this exemption where there may be a possibility of contagion; ill consequences await the most ingenious operator without the competent germicide.

Again it is argued that the great majority of our experts in the vast domain of surgery, using complete antiseptic precaution fail in producing as good results as Dr. Tait or Dr. Price. This must not detract from the value of the antiseptic precaution, for if *anything* be proven in surgery it is that the reproduction of disease, or infection is accomplished by transplanting bacteria; but it is due to other causes, the greatest being the lack of personal ability, mental power and dexterous facility combined with the confidence of the patient, begotten perhaps by the wondrous record and reputation of the operator.

The surgeon may have prepared for every onset of bacteria, but if he be himself incompetent, neither saltpetre nor bichloride of mercury will save him nor his patient from disaster.

The famous operators who get on without germicides, are more particular as to surrounding influences, such as time, place, barometer, filth, fear, hope, assistants, etc., etc.

There are so many risks likely to be overlooked when we let the great light of antiseptic relief satisfy our anxiety, that one must be a great general who meets and successfully combats them all. That time is never wasted which is spent in watching and studying the preparation, manipulation and management, both before and after the operation, of a man of vast experience. We should consider that man as good a seaman who avoided the shoal, as one who piloted his boat through it.

It is vastly better to steer clear of complications than fight them. Courting the patient's confidence is our best evidence of gallantry. Agreeing with superstitious victims as to Fridays and fatal anniversaries, and changing conflicting dates is not weakness but strength; better and easier is it than trying at this period to inculcate in their minds the idea of a higher education.

At an imperative operation the omission to quote to the patient favorable statistics is a blunder, and in contrast to padded results tabled for our own delusion by would-be surgical bombasts.

Experience proves the danger of operating while the barometer is lowering.

Personally I am satisfied that the morning hour is the best for the operation, although advices from abroad make it afternoon.

* Read before the Department of Surgery of the Minnesota State Medical Society, June 16, 1892.

The empty stomach, the night's rest, and especially the waxing resources of the day, which are so much greater than those of the night, commend it to me.

Next to the patient's confidence one's own is of value. The timid operator who delays, who is incomplete (danger lies in what we leave; not what we remove), who continually relies upon associates, upon repeated last looks, like lover's last good byes, who doubts about drainage, etc., etc., immensely damages the successes under contemplation.

We believe it to be far better to have one's own assistant for all operations, and that all compliments, consultations and divisions of responsibility should be made beforehand.

It is necessary first to be a man before one can be a surgeon. The qualifications of the first are multiple enough, and the standard must be to the individual himself satisfactory, but of the latter's equipment considering what he has to meet, no knowledge should be considered too trivial, no dexterity or excellence too great to be obtained.

We deprecate undue haste, but unquestionably the patient is in constant and increasing danger while depressed by anæsthetics, from the necessary or unnecessary exposure, the lowering temperature, from the rapid evaporation from the body's surface, by reason of irrigation and damp covering, and the constant sanguinary depletion, great or little.

The time of such exposure and irrigation of the divided sensory filaments should be shortened as far as possible by the strenuous cultivation of expert manipulation.

As to the question of which precaution may be dropped, the best preparation for success is to employ every one that you would require were you yourself the patient.

And after all is said and done, when one is fully prepared to ensure constant success in surgery, we believe he is one of the most learned men on earth, and his life and work too valuable to be spent on anything else.

PRURITUS ANI ET VULVÆ.

℞ Calomel..... .....gms. 5.
Vaseline .....gms. 35.
Apply locally.

FORCED RESPIRATION (FELL METHOD) PER FACE-MASK, AND TRACHEOTOMY IN DIPHTHERIA.—REPORT OF CASE.*

By GEORGE E. FELL, M. D., F. R. M. S.,
OF BUFFALO, N. Y.

The following case is presented with the belief that it has some features of novelty of an interesting character and

1. To illustrate how forced respiration may be of great value in surgical operations associated with conditions of asphyxia.

2. To illustrate its value per face mask and also tracheotomy in cases of membraneous diphtheria and croup.

3. To demonstrate the value of peroxide of hydrogen in asphyxia produced by membraneous exudates in the trachea and bronchi of the lungs.

The history of the case may also prove a valuable lesson to parents with children suffering from throat trouble and who hesitate to call a physician in time.

A resident of Buffalo, whose family consisted of wife and four children, the eldest a daughter nine years of age; a son seven years and three months; a daughter four years, and an infant son two years of age. The eldest daughter was taken ill with throat troubles and general disturbance of the system. She was quite sick and was taken from school. On the 29th of March, 1892, the eldest son was taken sick, and he, like his sister, was treated with home remedies until about 5 a. m. on the Sunday following, June 4, when the father discovered him in a cyanotic condition, breathing with great difficulty, and evidently in great danger. I was called about eight o'clock in the morning, and arrived at the residence an hour later. On examination I found the four children ill with diphtheria, the exudates being quite clearly marked in the eldest daughter and son. The son was respiring with great difficulty, and his life was in immediate danger. I informed the father there was only one thing that could be done at

*Read Before the Section of Surgery and Anatomy, at the Forty-third Annual Meeting of the American Medical Association, held at Detroit, Mich., June, 1892.

that time, and recommended tracheotomy as a means of holding the case, but held out no hope of ultimate recovery of the child. The younger children were also ill, the exudation however not so extensive, as the disease had affected them later than the first two. The mother desired the operation to be made. I sent for Dr. Colton, near by, to assist me, but before we were ready to make the operation the lad became unconscious from the cyanosis, and necessarily in a very desperate condition. He was placed upon a table and the initial incision made for the operation of tracheotomy. The blood was purple. No anæsthetic was used, as it was not necessary. A few moments after the first incision was made Dr. Colton called my attention to the fact that the pupils of the eye were rapidly dilating. I had fortunately prepared my forced respiration apparatus so as to have it ready for immediate use should occasion warrant, and had it not been ready I undoubtedly would have had the experience which very frequently comes to some surgeons, of death occuring during the operation. I immediately placed the forced respiration cup upon the face and respired for the little fellow, resulting in changing the blood to a bright scarlet in the wound in the neck and causing the return of auto-respiration. I proceeded with the operation, and found it necessary, before I completed it, to repeat the respiratory work with the forced respiration apparatus some six or seven times. in some instances having to respire quite a little time before auto-respiration was re-established. This is an unusual and peculiarly interesting fact, associated with the question of interference with respiration through exudates in the respiratory tract, that it is possible (it may be for a short time only) to breathe, retain the life of a patient, overcome the influence of the exudate and tone up the system so as to enable auto-respiration to be carried on. I completed the operation and placed the tracheotomy tube in the trachea,and even then found it necessary before consciousness returned to respire some time for the lad. After becoming conscious he breathed with very little trouble for quite a period of time. The general treatment directed was a spray application, to the throat and nasal passages, of the peroxide of hydrogen, about 30 per cent. aqueous solution. The father was directed to use this in the wound in the neck if found necessary. The afternoon of the day of operation revealed a condition similar to that which existed after the operation in the morning. The boy was moving around the house although the respirations were at all times more or less labored. At intervals the inner tube of the tracheotomy-tube would close up with the exudate and require frequent cleansing. The father stated on my second call that if he had followed my directions to merely spray lightly the wound in the neck, his boy would have died before my return. He found it necessary to place the tube of the spraying apparatus in the opening in the neck, or in the tracheotomy-tube, frequently to prevent the cyanotic condition from ensuing; that the "spray appeared to liquify the membrane, or the mattery substance, and cause it to come away in a foamy, frothy state." During the afternoon the condition of patient became worse, the membranes filling up the trachea apparently, so that Dr. Colton, who was present, applied the forced respiration through the tracheotomy-tube, again relieving the little patient from the severe dyspnœa which prevailed at the time. Sunday night the case progressed about the same, frequent resort having to be made to the peroxide of hydrogen to enable the little fellow to get along at all. On Monday and Tuesday extensive membranous casts were coughed up and passed out of the tracheal opening. The boy retained his vigor under the adverse conditions existing until Tuesday afternoon, when the exudate seemed to be increasing and interfered with the respiratory efforts, which condition could not be overcome, even by the forced respiration-apparatus, and about eleven o'clock Tuesday evening the patient died from exhaustion and heart failure.

The other patients in the house had upon my arrival been placed upon the common method of treatment which I used in these cases, tincture of chloride of iron, chlorate of potash, bichloride solution and so on internally, with the peroxide of hydrogen spray used every ten to fifteen minutes. While the exudates in their cases were very extensive, there appeared to be no serious invasion of the lung tissue and they both made a nice recovery without any serious complications.

It was very clearly evidenced in the case

of the boy that he would have died before I could possibly have performed the operation of tracheotomy had it not been for the forced-respiration apparatus. How many cases of a serious character might be benefited, or have life retained by such work, and tided over the most serious results, cannot be foretold. It is unreasonable to assert that some patients may not recover who are as seriously sick as was this young boy.

Regarding the peroxide of hydrogen, its value was unquestioned. It produced liquefaction of the membranes in the throat; but whether a weaker solution would have proved more satisfactory or not, I am not prepared to state. As mentioned, the solution was about 33 per cent., and this apparently produced no uncomfortable effect when sprayed into the tracheal wound. This treatment appeared grateful to the patient in his distress, as did also the forced-respiration application when it was made. In fact he eagerly requested that it be utilized later in the case, as it had relieved him once or twice. But of course, the difficulty was in the prevention of the exudates, which ultimately prevented the respiratory process from being carried on, weakening the patient so that the heart succumbed to the strain put upon it. I think there is no question from the result of the cases that had this boy been placed in time under the treatment to which the other children were subjected he might have recovered.

This paper is presented to this Section on account of its bearing upon an operation the surgeon must frequently perform, and if through means of this character the surgeon may be prevented from experiencing that most unenviable notoriety of losing a case during an operation it will be worth the time expended.

MORPHINE-VASELINE.

The following formula is proposed as an agreeable and easily absorbed combination:

℞ Chloret. morphic .....gr. iij.
Chloroform. pur.....f℥ij.
Vaseline .....℥j.

The chloroform favors the absorption of a larger amount of the morphine and causes it to be evenly distributed.—*Hospitals-Tidende*, No. 32, 1890.

"COELIOTOMY," VERUS "LAPAROTOMY," AS A SURGICAL TERM.

By ROBERT P. HARRIS, A. M., M. D., PHILADELPHIA.

When you perform an abdominal section, and report the case; under what scientific term do you describe the operation? You probably call it a "Laparotomy," because hundreds of operators are in the habit of using the same word, or its synonym, in a dozen countries and languages.

Where did this term originate? You say it has a Greek derivation (the language of Greece having been the tongue of the first anatomists) and comes from two words, *lapara*; and *tomæ* to cut. Now, what did the Greeks call the *lapara?* It was certainly never the abdomen.

Did you ever look carefully into an ancient Greek anatomy to find out what the abdomen was really called in their language? The word *belly* appears ten times in the English version, of the New Testament; did you ever note that the original Greek has the word *koilia*, and never *lapara* in these ten places?

Rufus, of Ephesus, a distinguished physician and writer, born A. D. 112, wrote a paper entitled "Names of the Parts of the Human Body," in which he has this significant sentence: "The *omphalos* (navel) is the hollow which occupies the middle of the *koilia* where we cut the veins that nourish the fœtus, the middle part of the hollow is the *akromphalon*" (top of the naval.)

"Lapara" is a very old Greek term, and was applied in the time of Hippocrates to the parts between the short ribs and the iliac bone (the flank), and scores of old lexicographers have thus defined it. The operation for lumbar hernia, or laparocele, was a true laparotomy; and so, also, is that of lumbar, or laparo-colotomy. The term *lapara* originally meant a hollow, and was for this reason applied by the early anatomists to *the hollow of the waist*. It was never used to designate a convexity.

The misapplication of the term "laparotomy" commenced in the year 1811 in the medical thesis of a Wittenberg student of the name of Fiedler, who wrote in Latin under the title "De Laparotomia." He had witnessed a true laparotomy performed

on October 17, 1810, upon a man of fifty with a diseased colon, as he lay on his right side. Fiedler wrote again in 1817, and took it upon himself to coin such distortions as "laparo-gastrotomia," "laparoraphia," and "laparo-hysterotomia"—his desire seeming to be to supplant the term "*gaster*," which really meant the belly, by the word "lapara," which a careful investigation would have taught him was not its Greek synonym. The mystery is how an error of this kind ever made the progress that it has in leading the medical world astray.

"*Koilia*" being the Greek word for abdomen, the natural synonym of gastrotomy in its old meaning is "coeliotomy," pronounced soft (se-le-otomy). This is not a new coinage except as to its terminal, for we have long had *coelio-paracentesis* for tapping the abdomen. The term coeliotomy has been adopted by Prof. Sänger, of Leipzig; by Dr. J. Greig Smith, in his *Abdominal Surgery*; by Profs. Keene and White, in their *Text-Book of Surgery*; and by a number of well-known medical writers. This adoption gives us the compound terms *coelio-hysterectomy* (Cæsarean section) *coelio-hysterotomy* (exsection of uterus through the abdomen,) *puerperal coelio-hysterectomy* (Porro-Cæsarean operation), *coelio-nephrectomy* (abdominal exsection of the kidney), etc.

What characterizes the present position of our condemned term is its wonderful tenacity of hold in the nomenclature of gynecological writers who have admitted the error of its application in abdominal surgery. Two years ago I published a classical pamphlet on the subject and sent it to prominent writers in thirty different countries. I also sent a copy to every Fellow of one of our leading national medical societies just before it met in annual session in 1890, and their letters attested its effect upon their sense of reason. It convinced them that *lapara* was not the abdomen and that *koilia* was; but it did not break up the habit of use, as shown by the fact that four papers entitled "laparotomy" appeared in their *Transactions* for 1891, and the term was time and time again made use of throughout the volume, but no one said "coeliotomy" as much as once. The old rut is so easy to run in, and the laparotomy wheel will get in. It took eighty years to propagate the error, and it will take time to correct it.

Selections.

ABORTION—A LANDMARK OF GYNÆCOLGY.

By FRED. BYRON ROBINSON, B. S., M. D.,
PROFESSOR OF GYNÆCOLOGY IN THE CHICAGO POST-GRADUATE SCHOOL; ATTENDING SURGEON TO THE WOMAN'S HOSPITAL, ETC.

Abortion is the expulsion of a fœtus from the uterus before the fourth month (no doubt the fallopian tube aborts many embryos into the peritoneal cavity when conception occurs near the fimbriated end). To understand the evil effects of abortion, one must analyze the anatomy (structure) and physiology (function) of the organ called the uterus. This organ consists of two parts: (*a*) the uterus and (*b*) the cervix. The function of the uterus is gestation and expulsion. The function of the cervix is protection. The crevix is a guard to the uterus; it is the faithful sentinel that wards off infectious matter from the uterus; it tells the uterus to quiet its troubled action. The cervix is the ante-room of a lodge where the guard strictly demands a password for entrance or exit. It does not share in gestation; it simply mechanically expands step by step with gestation, because the expanding uterus demands it. The cervix differs in structure from the uterus: (*a*) it has a different blood-supply; (*b*) it has a different nerve-supply—sober spinal nerves preponderate in it, while the sympathetic with its periodic rhythms predominates in the uterus; (*c*) its glands differ from the uterus; (*d*) its muscular substance is different. The cervix is generally still; the uterus is generally in a rhythm.

Now, an abortion is bad because it is unnatural, while a labor is natural. The cervix is never prepared far an abortion, while the uterus is always ready to start one.

From what has been said, it may be seen that the dangerous organ in abortion is the cervix. It is dangerous because it will not remain open. As soon as the fœtus is expelled, the cervix contracts and closet up the cavity. With a closed cervix, the tubes act as sewers, and the peritoneum as a sink-hole of infection. Now, the greatest principle in gynæcology is *drainage*; and abortion cannot have good

drainage, as the cervical canal closes the sewer. Then gonorrhœal and various puerperal infections run riot. The woman does not have much, if any, flow—so she gets up and walks around, with her infectious enemy in close communion. Her extra exertions weaken her and bring more blood to the pelvis, which causes more secretions for the germs to thrive in, while the closed crevix allows no escape for the accumulating germs and secretions; these, taking the direction of least resistance, go through the fallopian tubes. The woman never recovers her elastic, juvenile step. It is common talk for a woman to say: "I have never been well since I had a miscarriage."

Now, I claim that, in those cases of abortion in which the woman is an invalid from pelvic disease year after year, the infection is gonorrhœa. In many cases it is the very gonorrhœa (endometritis) that caused the abortion. The gonorrhœa and spermatozoa were put into the woman's vagina at about the same time. Both progressed together until—physiology and pathology conflicted—abortion! Gestation progressed until the excessive rhythmical motion of the uterus conquered the cervix and opened it up.

Abortions frequently render a woman sterile. This is done by: (*a*) altering the tube so it will not transmit an ovum; (*b*) adhesions will not permit the fimbriated end of the tube to apply itself to the ovary; (*c*) the endometrium becomes so diseased that it will not gestate; (*d*) graafian follicles become so diseased that they will not be fructified. The ovary, I have noticed, after such infections becomes degenerated cystically. The whole story of sterility after abortion is: Infection, inflammation, adhesion, and degeneration.

The general practitioner's idea of abortion seems to be of a man shaking an apple tree. If a few apples fall off, there is nothing further to be done but to dispose of the apples. He seems to forget that the main damage is done *to the tree.*

Much is said about criminal abortions in this country. We only know of a criminal abortion because the woman became infected during the process. Many doctors perform abortions on woman for *money* or *pity.* In almost every abortion that I have known of being produced, the woman had more or less infection. The men who do such work are generally rough and unskilled, and do not understand antiseptic or aseptic principles. I saw one case where the physician had torn the vagina and dragged some intestines out of it. He mistook the mesentery for the placenta. She died. Not far from where I lived, a woman thrust an instrument into the abdomen through the vagina, and died. Dr. Thomas reports a case where a woman passed a rib of an umbrella up through the vagina, and it went on through the diaphragm into the lungs; she died from the effects some time later. Even practicing physicians who criminally produce abortion do it very clumsily. A young woman of 24 came to my clinic at the Woman's Hospital; she had had an abortion produced on her by a neighboring physician, and he had actually lacerated the whole depth of the cervix for nearly three-fourths of an inch. A year after, she had a solid bunch of old adhesions on the left side—opposite the side of the laceration. It was presumably salpingitis and cystically degenerated ovary.

The line of pathological progress after an abortion is: (*a*) Endometritis; (*b*) *plus* endosalpingitis; (*c*) *plus* ovaritis; (*d*) *plus* peritonitis; (*e*) *plus* lymphangitis; and (*f*) *plus* phlebitis. Lymphangitis and phlebitis are rarer than endometritis *plus* salpingitis, *plus* ovaritis, and *plus* peritonitis.

I have seen in autopsy the connective tissues in the broad ligament as white as snow, but pyosalpinx existed. Another remarkable fact I wish to record is that I have seen double pyosalpinx with an endometrium which looked absolutely healthy. I have become convinced, of late years, that endosalpingitis in its worst forms can and does exist with a normal endometrium.

The statistics of abortion are very delusive, and so untrustworthy that they are not worth copying. Deaths from abortion are charged to different causes; but many occur, and many women are made invalids for life thereby. The Europeans call criminal abortion the American sin, while the American retorts by saying the European sin is illegitimate births. The American sin is the worst, for it causes a man to attack a defenseless babe which, cabined and confined in its narrow uterine quarters, is totally unable to defend itself. It is cowardly, because there is no bravery in killing innocent and harmless animals.

The *causes* of abortion are very various,

and not always ascertainable or even understood. But we must look for the causes of abortion in: (*a*) the uterus (and mother); (*b*) in the fœtal membranes; and (*c*) in the fœtus itself. In accounting for abortions, one must not forget the patient's previous history. Some predisposing cause has no doubt long existed. The cause of abortion often lies far ahead of the expulsion—the abortion is simply the effect of some old persistent cause. I found many abortions among women of an outdoor, active life, but I think that was due to trauma, for I noticed that as the seasons changed and these woman began a new kind of work numerous abortions followed. I also noted that abortions from trauma or new and excessive bodily exertions passed over frequently with scarcely a trace of infection. One can easily note, in farm life, that, among women who suddenly begin to bind in the harvest field, many have an abortion in a few days (from trauma). Or let the season for digging potatoes arrive—when, especially in German communities, many women work in the field—and some abortions will follow.

The condition of the mother must be examined. I was once called to a woman in labor who had a very distinct attack of measles. When the child was born it was covered with a most intense measle rash. The mother's measles not only precipitated the labor, but infected the child with measles also. Acute infectious disease plays a rôle; also constitutional disease, excitement, or intense emotions (which means that the abdominal brain sends too great an irritation over the hypogastric plexus and creates excessive rhythm in the uterus). Among predisposing causes must be also mentioned the general spreading of catarrhal diseases. Endometritis accounts for many abortions; nor can we overlook diseased kidneys and heart as causative factors.

The fœtal envelopes play a rôle in abortions. The membranes are liable to diseases. The fine chorionic villi which projects from the fœtal ball like fine hairs may enlarge to the size of a hazelnut and make the pathological condition known as hydatids of the chorion. Naturally the small chorionic membrane looks like a shaggy ball of wool. Its surface appears like the pile on velvet. But what a wonderful change occurs when all these fine villi of the chorion swell up and assume the appearance of a bunch of large transparent grapes! Several specimens of chorionic hydatids have been shown in Chicago lately. My friend, Dr. Bailey, showed me a splendid specimen of these hydatids last month, taken from an abortion of four months. In Dr. Baily's case the chorionic villi were club-shaped, there were countless jelly-like transparent cysts covering the chorion. The contents of the hydatids were of a viscid nature. Many of the cysts had very small pedicles. I noted that the cysts were so numerous that the child could not get sufficient nourishment from the most diseased part of the chorion. In this way the normal chorionic villi were transformed into pathological villi (cysts), and the fœtus was starved to death. Indegeneration of chorionic villi the fœtus is starved, and abortion results. In that part of the chorionic villi which persists and forms the decidua serotina, or discordal placenta, of man, I have often found circumscribed patches of hard cicatricial tissue. The salts of calcium are deposited in such diseased points. Such spots may be found on the remains of old limited inflammations, and no doubt such localized inflammations frequently proceed to abortions.

The placenta may be so placed that as the uterus expands it will be torn from the uterine walls and thus cause hæmorrhage, followed by abortion. But it must not be forgotten that the placenta is not very firmly attached to the uterine walls, and slight trauma will often loosen it. I have examined scores of animals, and the wonder to me is how such a weak connection between uterus and placenta can last through gestation without a rupture. The pig's universal placenta peels from the uterine wall with very little pulling. Though the cotyledonous placenta of a cow is more strongly attached to the uterus, yet slight traction destroys the connection. Unumbered abortions arise from the separation of the placenta from the uterus, from mere trauma, *e. g.*, a jog, a misstep, a rough ride, or an active walk.

The amnion may contain an excessive amount of fluid, and abortion result. Reports give as high as seven gallons. I saw a woman in Prof. Braun's clinic with such extensive hydramnios that life became endangered. Prof. Braun placed her under chloroform, dilated the uterus,

and delivered her of twins—which he had previously diagnosed. It is probable she would have aborted in a few days. The uterus may be so rapidly distended by hydramnios or chorionic hydatids as to quickly cause abortion. The amnion may contain too little fluid, and various inflammatory adhesions may result—the cord may adhere to any part of the body; the fingers may become adherent—and abortion follow.

So far as I can see, from the examination of scores of animals in pregnancy, and also from a practice of ten years, in which I have had quite a number of abortions among women, it seems to me than the death of the fœtus is the most frequent cause of abortion. Fœtal death becomes more impressive as a man examines gestation in its early stages in women, or in pigs and cows in the slaughter-houses.

It is a surprising matter that such a delicate thing as an ovum survives in an animal with such varied movements. The beginning fœtus is as soft as jelly, and its structures are as delicate as a spider's web. Active movements are apt to snap its delicate structures, and it will often pass off in *solution*. I noted that great numbers of fœtal pigs, from ¼-inch to ¾-inch long, in the slaughter-house, died from *hæmorrhage*. The smaller the fœtus, the more apt it is to die of hæmorrhage. The hæmorrhage mostly occurred at the end of the umbilical cord or in the abdominal cavity. The little fellow was smothered by blood. Such hæmorrhages constitute a great causative factor in the death of young fœtuses. The hæmorrhages of women have floated many an embryo to an early grave, and even the matron or doctor is none the wiser. Of course, when the embryo dies from being smothered by blood, it becomes a foreign body and is then aborted.

Syphilis is another cause that kills the fœtus, and the result is abortion. This is no doubt the cause of habitual or recurring abortions. The fœtus acquires gummata in its viscera (liver, kidneys, spleen, etc.), and death ensues. The bones of a syphilitic fœtus are very distinct, and a post-mortem in a dead fœtus will tell a physician whether to treat the mother and father for syphilis. It should be remembered that long pre-existing causes should be sought for in abortion, especially in repeated abortions.

The fœtus may also die from any disease of its delicate viscera. I have seen intrauterine peritonitis show very impressive changes at the autopsy. Under the causes of fœtal death would come the torsion of the cord to strangulation; abortion would follow it.

A curious feature I have witnessed many times in the lower animals is that after the death of the fœtus it is not immediately expelled, but *decomposes*, *mummifies*, or is transformed into *adipocere*. I have seen some similar things in women. The best explanation I can offer for such a retained fœtus is *tolerance* of the uterus; yet this is not a very satisfactory explanation. Such fœtuses will remain a very long time in the uterus. In the cases of mummification and adipocere the endometrium often appears healthy and normal. In the case of fœtal decomposition I have often found retained bones sunk deeply into the uterine wall, which was several times its natural thickness. Yet all such animals were fat and had been killed for butcher's meat. The blood-supply of the uterus became lessened, and the innervation-centre did not act normally. In such cases in pigs the uterus would contract so firmly down on the mummified or adipocere pig that the uterus would appear node-like; a bulb-like swelling would appear where a fœtus lay, and between the fœtuses the uterus would contract to a circumference several times smaller than that of the bulb or fœtal node.

An important matter in abortion is to be aware of the *dangers* that it causes. I will place the dangers under a few heads.

The first danger of an abortion is *hæmorrhage*. I have seen many women almost bleed to death from abortion. I lost one from bleeding. And if they did not die from great loss of blood, they were ill for months from want of blood. They lost so much blood that what followed was—mal-nutrition, anæmia, and neurosis, a triumvirate in chronic female disease. So hæmorrhage must be controlled.

The second danger of abortion is *infection*. This infection may be followed by endometritis, salpingitis, ovaritis, partial peritonitis, lymphangitis, cullulitis, and phlebitis; the last five, from infection following abortion, are common diseases.

Then I have had fatal suppurative arthritis following labor.

I have also had fatal embolism following labor. Both arthritis and embolism may follow abortion.

A fifth danger may be the entrance of air into the veins.

Writers of complete works on abortion mention such things as tetanus and uterine hydatids following abortions, but I never saw such a case. I have seen puerperal mania, or melancholia, follow: but it was not very dangerous, except that suicide was attempted.

I have examined a large number of women who have had abortion, and what one finds on examination is the following: on introducing the finger into the vagina, an irregular, boggy swelling on one or both sides of the uterus. In my practice, the swelling has occurred seven times out of ten on the left side. The uterus may be normal in position or generally drawn more to one side than the other. This lateral boggy swelling of the pelvis is found between the uterus and the pelvic brim. After some experience one can usually distinguish the crooked, contorted, nodular tube and the ovary, in a mass of exudate. The more gently the examination is done, the more is discovered. The mass is generally up *toward the fundus*; hence it is probably tubal, and not cellulitis. One generally finds the pelvic peritoneum somewhat thickened on the diseased side. The disease lies mostly on the left side (seven in ten), on account of the dilatation and contraction of the rectum, and also on account of the venous current emptying at right-angles to the renal veins on the left side. The left plexus pampiniformis appeared to me to be larger than the right in nearly forty bodies dissected. If the boggy swelling in the pelvis appears within two weeks after the abortion, and is as large as an egg, it is likely a cellulitic and not a tubal abscess of that size occurs much later.

Women with these pelvic swellings generally have painful menstruation. They have crooked, contorted, and convoluted tubes. From the crooked tubes they have premenstrual pain, or tubal colic, because the diseased tube, hampered by pathological conditions, cannot go through its peristalsis. I have noted that those women have much pain because the *rough*, untutored gynæcological finger has actually irritated the tubes into peristaltic movements; such pain will often last two hours.

Large experience enables one to learn from *resistance* in pelvic examinations. But the young gynæcologist should place the woman on her back, with thighs flexed on the abdomen, and then proceed *gently* and *slowly* with the bimanual pelvic examination. He should examine systematically every region of the pelvis. Though practical gynæcology is hard to learn, because of the lack of teaching clinics for digital examinations, yet much can be learned from a single cadaver in a couple of weeks. The *treatment* of abortions may be summed up in the following:

1. Rest.
2. Drainage.

If one is called to see a woman who considers herself pregnant and has symptoms of aborting, he must satisfy himself by examination on these four points: (1) Has she had *hæmorrhage* from the vagina? (2) Has she had pelvic *pain?* (3) Has she had *vomiting*? (4) Is the *os dilated?*

Hæmorrhage from the vagina is nothing but a symptom, and may pass over. Pain is very delusive, and but little reliance can be placed upon it. Vomiting is of a more suggestive character, because it probably comes from profound disturbance in the ganglia in the uterus; this irritation is carried up to the abdominal brain, where the irritating force is reorganized and then reflected on to the stomach by way of the gastric plexus, and vomiting results. Now, a sign is a distinct clew to the disease; a symptom is only an indication of a pathological condition; hence we say hæmorrhage, pain, and vomiting are mere symptoms. However, if they are combined, *i. e.*, occur together, the presumption is strongly in favor of abortion being present.

But the *dilatation of the os* is the *sign* of abortion; when the os is dilated, the uterine contents are pretty sure to abort sooner or later. Hence digital examination of the os is the only real clew to the condition of the uterus. Under ordinary circumstances, if a woman aborts (traumatism being excluded), it will be close to the climax of a menstrual period. The first thing to do is to put the woman to bed and insist on her remaining there. Very frequently, when the physician arrives the fœtus has passed. But the placenta is still in the uterus. Right here arise two classes of gynæcologists: one class would let it alone—leave it to nature; the other

class would remove it. It is very difficult to decide which course to pursue in each case. Only years of experience will enable a physician to judge for himself. I would say this much from my experience: if one can remove the placental remains aseptically, it is the wisest plan; but if there is any doubt, it is better to leave them alone. Remember that when a woman has a child without having been subjected to digital examinations, she is pretty sure to escape puerperal fever—I have never seen puerperal fever in such a case.

The midwife and the doctor carry puerperal fever. But we will take a case: Dr. A. is called to Mrs. B., who is aborting. What shall he do? If the pulse and temperature remain normal, he had better let her alone in bed, and do nothing, and expect. If fever arises, the best way is to put Mrs. B. to sleep and lift her on a table; then clean out the vagina with $HgCl_2$ 1:000. Now seize the anterior lip of the cervix with a volsela and draw it down, introduce a dilator, and in *not less than* five minutes dilate the os. Be sure to dilate slowly. Introduce the finger and break up some of the placental adhesions. It is possible that a forceps will be required to draw out the fœtus, but the whole thing soon rolls out. Now curette every corner of the uterus, using a dull instrument. The uterus should then be irrigated with hot water, and this will soon make it contract down. After it is thoroughly clean, pass some well-boiled gauze to the fundus, pack the vagina with it, and put the patient to bed. The gauze can be removed in from two to four days. If it be done aseptically, the woman is safe 97 times in 100.

The indications for this kind of treatment in cases of abortion are: (1) High temperature and pulse. (2) Hæmorrhage. (3) Retained placenta.

I have also treated many women expectantly. If the fœtus was passed before I arrived, and some placenta remained, I have many a time left them to nature, and they recovered. I will say that, though a man be never so clean, at an abortion where the patient is infected with gonorrhœa she may yet have a distinct exacerbation of her tubal and pelvic trouble, because the active process of parturition has induced the germs by active feeding to thrive faster and invade new fields through new lesions. One must be just as clean at an abortion as at a laparotomy.

The gynæcologist, when called to a case of abortion with a general practitioner, will likely want to empty and curette the uterus; and that is often what the practitioner, will oppose—he thinks the gynæcologist wants to do too much and show too much "skill" to the family. The general practitioner will often say: "Let her alone; give her a physic and a little medicine, and she will be all right." But one must not allow high pulse and temperature after an abortion to go by without *immediate* invasion of the uterus. The thing to find out, on a visit to a woman who has aborted, is the amount of temperature she has. The pulse is not so good a symptom, as she may have a high pulse from large losses of blood. The only safe place to take temperature is in the rectum. High temperature means infection, and every means should be used to stop it.

Another feature arises in abortion. One is called to a woman aborting, but the event is only known to be surely coming from os-dilatation. She is losing some blood, but the expulsion will not occur for many hours yet, and you are afraid she may lose too much blood in your absence. In such a case the whole vagina should be well packed with cotton balls (well boiled) dipped in a 4-per cent. solution of boracic acid. This will prevent serious hæmorrhage, but will allow the uterus to expel its contents. After 10 to 20 hours the cotton balls can be removed, and likely the fœtus will be in the os or vagina.

Drugs are not of great service in abortions. Ergot would not aid a very great deal in expelling a small piece of retained placenta, and it only acts temporarily.

To properly treat all cases of abortion requires all the skill a man can command.

In discussing abortion (the fourth landmark of gynæcology), I have not attempted to be at all systematic, but have rather dotted down rambling remarks on the subject.—*Med. Age.*

Lemonade for diarrhœa—Hayem: (*Le Bull. Med.* Sept. 21st 1892.)

℞ Acidi Lactici.....10 grammes
Syr. Simp.....200 grammes
Aq. Dest.....800 grammes
M. Dose half glassful.

This is especially recommended for the chronic diarrhœa of adults.—The lactic acid acts as a tonic and germicide.

Society Reports.

THE SURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, August 8th, 1892.

The President, Dr. A. M. Cartledge, in the Chair.

RESECTION OF KNEE.

Dr. Jas. Chenoweth: Mr. President, I have a patient to exhibit, who was operated upon (resection) in January, 1891, by Mr. Mayo Robson, of Leeds, England, for tuberculous knee joint. I thought it would be interesting to the members of the Society to see the results of this operation. The patient is five and one-half years of age; had tuberculous disease of the knee joint for a year previous to the operation, and had worn splints constantly; was under treatment in the hospital most of the time. You will observe there is very little shortening of that leg and slight motion in the joint. He still wears a felt dressing. The child is in good health at the present time.

The leg was perfectly straight before operation.

Dr. W. C. Dugan: The question comes up here whether or not we should resect these cases in children. This question has arisen out of the fact that after the operation improperly performed, shortening was permanent. This question has been discussed a great deal of late years, some objections being raised to the operation, but I am sure in this case there will be no shortening, that is, there will be no more than after the operation in an adult, since there was no interference with the epiphysial cartilage. Shortening, or, rather, a failure of the bone to grow in length, is invaribly the result of injury to the epiphysial cartilages—an accident which should rarely, if ever occur; so I take it that the objections are without any real foundation, and should never be arrayed against this operation, which, in my judgment, is a good one for certain cases. I think, however, that the leg is a little too much at an angle in this case.

REPORT OF CASE—RESECTION OF KNEE JOINT.

Dr. W. L. Rodman: Mr. President—This is the patient I hoped to have had present at the last meeting of this Society, but, as stated at the time, he was ill and could not come. I wished particularly to exhibit the patient at our previous meeting as a companion case to the one Dr. Dugan presented.

A year ago last March, while working on the roof of a house, this young man fell some distance and struck his knee. After being taken home he noticed that there was a small indentation in the skin, as if it might have been made with the point of a nail, but he was satisfied that the nail had not penetrated the joint; it did not feel as if there was anything in the joint. He told his family physician that he was quite certain it had only gone through the skin. A very severe synovitis developed two or three days after the accident and the physician in attendance attributed it to the blow—just to the external traumatism. I was called to see the patient five or six days after the accident and we were still able to see a little opening in the skin. I found he had temperature of 102° or 103° F.; tongue very much furred; suffering great pain; joint was very much distended: the skin over the joint was very glistening, and the patient perspired profusely. I was satisfied that suppuration in the joint had taken place; I believed, also, that severe synovitis as he had at the time would not have resulted from external traumatism. I thought that the nail must have entered the joint, although the patient and his physician did not think so. As there was evidently a good deal of pus in the joint, I insisted upon doing an arthrotomy, believing this to be best thing for him, even if there was no foreign body in the joint. I made a very free incision in the joint, and at once came in contact with a rusty nail, without head, two inches long. I then made an incision in the other side of the joint, putting in two large drainage tubes, and irrigated the joint with chloride of zinc 1 to 500. This was practiced daily for two weeks, and I then removed the tubes. About ten days, I think, after he was hurt, erysipelas developed on his thigh, extending from the knee joint up to the hip. You will notice a number of scars along the front and lateral aspect of the thigh where I made incision in a number of places and evacuated pus. The cellular tissue of the thigh was almost entirely destroyed by suppuration; many pieces several inches long were removed at different

times. He had a very severe attack of erysipelas, and was laid up on that account for about two months. For the last fifteen months he has had about as good use of his leg as ever he had. The motion is not quite as good as it was six months ago, owing to his having hurt his knee recently, still, you will see the motion is very good indeed. He is able to work, and has been working ever since a short time after the operation, and walks about as well as he ever did, having just as good use of his leg as before the injury.

Case No. 2:—This young man probably some of you will remember was shown at a meeting of this Society some time since at the Pendennis Club. He came to me from Trimble County (Kentucky) with a badly deformed knee, the result of suppurative synovitis of the left knee joint, which was caused by an axe wound into the joint. The suppurative synovitis which was opened at several different points by the physician in attendance, and which opened itself at several other points, left the knee badly ankylosed. The leg was so completely flexed that the calf almost touched the thigh, as you will remember. It was really painful to see him walk. The ankylosis was bony, there being no motion in the joint at all. I put him under chloroform to test this, and there was not the slightest mobility. I sent the patient to the Norton Infirmary, and, after preparing him for operation, decided that the best operation would be a modification of the Rhea-Barton operation. I think this operation better than any other, although I did not do any of the regulation operations. After washing him thoroughly and keeping his leg wrapped in gauze for twenty-four hours, I made a semi-lunar incision extending from the internal to the external condyle of the femur. I removed the patella first and then removed a wedge-shaped piece from the lower end of the femur just above the joint, but, instead of cutting only partially through the femur as Barton did, I went all the way through. After doing this, on account of the deformity which had lasted for five years, the tendons were very much contracted, and the normal relation of the parts was so much disturbed, that instead of doing subcutaneous tenotomies, I made five or six by cutting from without. I preferred this to the subcutaneous method, as the normal relations of parts were so disturbed. There was a great deal of bleeding from the sawn surfaces of the femur, and this bleeding continued to such an extent after the dressings were put on that it saturated everything, even the plaster on the outside. This caused me to change the dressings a little sooner than I otherwise would have done. I think they were changed on the sixth or seventh day; the temperature had not raised in the meantime to above 100°F. and that was on the second day after the operation, there was a little odor to the discharges and I thought it safe to change the dressings at the end of a week. I found no suppuration at that time; it did, however, suppurate afterward at several superficial points —stitch abscesses. Several of us thought at the time that perhaps the leg was not quite as straight as it ought to have been, but the position now as you will see is about right; in fact, I think it is in an ideal position, fully as straight as it should be. He has not used his leg very much yet, but I think now everything promises to be favorable. The scars which will be observed on his leg were there before the operation, as a result of the suppurative synovitis.

Dr. E. R. Palmer: Can this man walk on his leg at all?

Dr. W. L. Rodman: He has not tried it yet. I did not want him to walk on it until it had thoroughly healed; he will begin to walk very soon.

I wish to further state in regard to this case, that I did not remove the articular end of the femur. Barton's operation is to remove a wedge-shaped portion of the lower end of the femur, but he does not go into the joint. I removed the patella and a large wedge from the lower end of the femur. I think he will have as perfect a leg as we could possibly expect in a case of that kind. I kept a ten pound weight on the leg for about six weeks, which evidently straightened it and put it in better position than it otherwise would have been.

LACERATED PERINEUM.

Dr. A. E. Cartledge: In lieu of a prepared paper, I wish to refer to what to many seems a hackneyed subject. Several years ago the journals and reports of medical societies teemed with the best methods of operation, and the conditions demanding operation, in lacerations of the perineum. As some excuse for my re-

marks upon this subject, I will say that there has been a temporary suspension of hostilities in this direction, within the last few months. I have no original operation to offer, nor can I add anything to what has been said of the importance of the perineal body as a means of support to the uterus, bladder and rectum. In brief, I would say that I think we can well afford in a practical way to look upon rectocele, and cystocele, when occurring before the menopause as results of either subcutaneous or open rupture of the perineal muscles; hence the only logical operation for these conditions is a restoration of the perineal body. We are all aware that many cases of so-called endometritis, cervicitis, uterine engorgement, etc., that are daily treated in the offices of physicians by local applications, are only temporarily relieved and must be permanently cured by a restoration of the perineum.

What I desire to say in regard to the operation is this: After a careful study of the various operations, and the practical application of several of them, I am convinced that no operation so far perfectly meets the requirements in this condition. The importance of uniting the deeper structures, which was first brought out in America, is the greatest advance of any step in the operation. A combination of the ingenious method of Tait which so thoroughly preserves all tissue in a place where this is important, with the subcutaneous union of the deep structures by the buried suture, seems to come nearer fulfilling the indications than by any other method of operation.

In recent cases, after making preliminary incisions by the Emmett and Tait method, I have thoroughly dissected the deeper perineal structures, and while I do not claim to be able to bring in apposition individual torn muscular fibres as some writers have, the deep muscular structures are thoroughly united by catgut, working up from the bottom and closing up to the skin margin. This is accomplished by a continuous or crossed suture. The finishing part of the operation is made by the introduction through the skin, traversing the entire pre-sutured area, with silk-worm gut sutures, these acting as a brace or support for the subcutaneous catgut suture, which I deem insufficient as they will probably soften and give too soon.

The result of this combination is a thorough restoration of the perineum, giving for the depressed, concaved appearance a full, strong, pouting perineal body.

DISCUSSION.

Mr. W. C. Dugan: I would like to suggest another method of suture for laceration of the perineum, that is, use a suture with a needle attached to both ends, beginning at the bottom of this V. shaped cavity, then crossing them and secure them on the sides of the cavity, then crossing and still higher secure them and so on crossing and fixing them half a dozen times, instead of tying them, and then finally bring them out and make one knot on the surface instead of half a dozen. I have enjoyed the paper very much indeed.

Dr. E. R. Palmer: A point in the physiological aspect of the question: The statements made bring to my mind three cases in which rupture of the perineum destroyed the capability of sexual orgasm in the women. One of these cases was operated upon very successfully by Dr. Anderson, and I learned afterward that sexual capacity was fully restored as a result of the operation.

Dr. Turner Anderson: I am obliged to Dr. Cartledge for bringing this subject before the surgical society. I want first to say a few words in regard to the operation as it is commonly performed: It is hardly necessary for me to say anything about the advisability of primary operation. Wherever the perineum is lacerated it is desirable that a perfect coaptation as possible should be obtained. All laceration of the perineum should be operated upon, and the operation ought to be done as soon as possible, for the reason that if the first operation is not entirely satisfactory, it will give something to build upon and be of material assistance in a subsequent operation.

I would like to have heard the essayist speak upon the subject divided; that is, complete laceration, and partial laceration. In the incomplete lacerations, the operation of Tait is very satisfactory, provided we make the incision deep enough. In my operations I use silk worm gut as suture, the procedure being a modification of the Tait operation.

Dr. A. M. Vance: With a laceration say two and one-half inches into the bowel, I do not see how a good result could be ob-

tained without suturing the gut separately down to the sphincter fibres.

Dr. J. G. Cecil: The question under discussion is one of especial interest; I consider it a very important subject from a surgical standpoint, because I believe that a successful perineal operation is one of the most difficult operations in surgery. Of course it is not surrounded with the immediate dangers on the table that we encounter in many other cases; not followed by the shock and other evidences that mark greater operations, but the successful coaptation of these ruptured structures with results which will show an improved condition, relieving the symptoms which have been prevailing since the accident, constitutes to my mind one of the difficult operations in surgery.

I believe that much of the discredit thrown upon Emmett's operation arises from the fact that it has been done by operators who have paid more attention to the skin than to the restoration of the ruptured muscles. Further, I think many operations for the relief of this condition have been unsuccessful because of a misconception in regard to what is called the "Perineal Body." Strictly speaking, there is no such thing as the perineal body. It is no more nor less than a muscular structure; you can dissect that structure as much as you please, and you can never separate that body which is called the "Perineal Body." It is simply the junction of these muscles, and when operations have been done to restore this torn perineal body, a space is looked upon, or, rather, a torn space, and the conclusion is that if this torn surface is renewed, the perineal body is restored; whereas, the ruptured muscles have retracted, their torn ends are not uncovered by the dissection, and consequently never reunited. I think many of the illustrations or sectional views showing the perineal body are entirely erroneous.

I, of course, agree with what has been said as to the necessity of these operations, and the symptoms which have been outlined by the essayist are those which are common, and failure to relieve those symptoms, is simply failing to get the proper conception of what is necessary in this operation.

Not long ago in another medical society, this subject was under discussion, and I remember one speaker, especially, who could not understand how it was that a pessary would restore the perineal floor in such a way as to maintain a retroverted womb; he then went on to detail his own treatment or management of these cases, in which he brought out his method of replacing the womb, then packing the vaginal space posterior to the cervix holding the womb up in that way until he could get a satisfactory pessary to hold it up. Now, the operation as detailed by Dr. Cartledge takes the place exactly of the cotton and pessary and so I pointed it out to the gentleman in question at the time.

In these cases the natural support of of the womb is torn away, and the only thing is to restore it; that is, restore these ruptured muscles and connective tissue in that region. The methods of doing the operation are so many and are so complicated that I must admit I have often been confused very much by looking at the pictures in the text-books. They all suggest methods of suturing, with sketches, etc., all of which looks very nicely on paper, but are difficult to understand. The description given by Dr. Cartledge seems to be the most satisfactory method; simply uncovering, bringing forward and suturing the parts which have been ruptured and separated, building up the pelvic floor by continued lines of suture. In doing this operation I think catgut preferable because it will be absorbed; it should be re-inforced by strong sutures running through the skin.

Dr. A. M. Cartledge: I simply want to say in reply that this paper does not intend to offer an entirely original operation for the restoration of the perineum. After carefully performing the various operations employed by the different men in this affection, I have attempted to combine what I believed was the best principles of each. If I had to confine myself to the method of operation of any one man, I should give preference to that of Marcy; that is to say, the use of the buried suture alone, after thoroughly exposing the torn deeper perineal structures. However, I have thought in many cases that owing to the softening of animal suture as early as the seventh or eighth day, some additional means of support or apposition would be of advantage. To this end I supplement the buried suture of Marcy with an external silk-worm gut

suture passing this in the usual manner, traversing the already apposed deeper structures, thus acting as a brace to the subcutaneous or buried suture of gut. Certainly my results so far have been better by this method than by the single method of Tait, the older method of Emmett, or the method of Marcy alone.

AMPUTATION OF LEG.

Dr. A. M. Vance: I have one case that I would like to report: I was recently called to the Sts. Mary and Elizabeth Hospital to see a man sixty years of age, who, about six or seven months ago, sustained a compound comminuted fracture of the leg. Dr. Samuel attended him and wanted to amputate the limb, but the patient would not consent to this, and he attemted conservative measures which were carried out. The fracture united and after the expiration of several months, erysipelas developed, going from the foot to the thigh, numerous abscesses forming along the leg and thigh. The foot suffered greatly, all of the tarsus being involved. The fracture occurred about the middle of the lower third of the tibia. Amputation was advised when I saw the patient in consultation with Dr. Samuel, but he still refused. Finally he consented to amputation, and, assisted by Dr. Dugan, I removed the leg about six inches below the patella. Owing to the man's advanced age, and condition at time of the operation, we hardly hoped to get primary union, the whole limb being very œdematous and the tissues much matted together, more serum than blood exuding when the Esmark bandage was removed. Two rubber drainage tubes were used, which were removed on the third day. I saw the patient day before yesterday and was very much astonished to hear that he would be out in about two weeks. I found as pretty a stump as I have ever seen, absolutely healed by first intention.

I will state that I have never before seen as perfect a result from amputation of a limb in a patient of this age, and especially when the condition of the patient at the time is considered.

Dr. Turner Anderson: I want to ask the members of the surgical society one question, and that is in regard to the propriety of using drainage tubes. It does seem to me that we have arrived at that point in which the amputation of limbs, for instance, can best be done without the use of drainage tubes.

APPENDICITIS.

Dr. W. C. Dugan: Since the last meeting of this society I have had a rather peculiar experience, having seen an unusually large number of cases of appendicitis. I have seen six cases, two died and four of the six were operated upon. One of the cases operated on died, the other one died without operation. The first patient a lady aged about thirty five, was in Indiana; there was a very large tumor most prominent in the postero-lateral aspect of the abdomen; temperature was low, ranging from 99° to 102° F.; patient had been treated for typhoid fever six or eight weeks. The attending physician called in aid, who made a diagnosis of pyonephrosis. I was asked to see the case and after making a careful examination, we concluded that we had a case of appendicitis. We made an incision in the abdomen, and found a circumscribed cavity containing several pints of very offensive pus. We operated through the loin; patient made an uninterrupted recovery.

No. 2. The next patient, a boy about sixteen years of age, I saw in the Southern part of this state. He was taken very suddenly ill with chills and severe pain in the left side of the abdomen near the umbilicus, and other symptoms which led the attending physician to diagnosticate intussusception. The boy grew rapidly worse, with symptoms of colic and complete intestinal obstruction. I saw him on the fourth day. He had had stercoraceous vomiting some time; profuse cold perspiration; in fact was in collapse. We opened the abdomen and removed about a gallon of offensive pus. When the cavity was opened the pus spurted up eighteen inches. The patient died of sepsis on the third day after operation.

No. 3. Another case I saw with Drs. D. T. Smith and Turner Anderson a few days ago; tumor plainly visible. The history of this case extended over two weeks; patient was taken with colicky pains in regions of the umbilicus. Lead colic was suspected inasmuch as he had been painting. The patient was able to be up and around for several days after first visit by Dr. Smith, but in walking assumed a stooping position, favoring right side. Two weeks afterward he was taken worse

and Dr. Smith was again called and for the first time found the enlargement in right side with pain accentuated there; I was then asked to see the case in consultation. Upon examination we found a tumor of considerable size in the caecal region, and extending down into the pelvis; we diagnosticated appendicitis. There was one symptom I desire to call particular attention to, and that is pain in the bladder with frequent micturition, Now, this is not at all uncommon and the explanation is rational. We should not mistake this for cystitis. Dr. Anderson was asked to see the case and he made a very careful examination and said that he had never seen a case where he thought surgical procedure advisable, but thought this was one of the "border line" cases, and if we decided to operate, he would agree with us. After discussing the matter we concluded to wait until the next morning, unless something occurred in the meantime. At nine o'clock the same evening we had another consultation, and decided to send the patient to the Infirmary for operation. The next morning we found the patient very much improved; pulse which had been 130 the day before was 92; tumor had disappeared with the exception of a slight induration, and we were at a loss to explain it until the mother showed us the vesssel which contained about a pint of pus, which patient had passed by the bowel that morning. This is a very important case indeed, and I think we have made a mistake in not operating. I believe that we subjected this boy to very great danger in allowing it to run over. In this case I would not have opened the abdominal cavity until after exploring the subperitoneal space and found the pus to be intraperitoneal. I think in all such cases where the tumor is low down, this precaution should be observed.

No. 4.—Another case I saw a few days ago with Drs. Baker and Bailey; the patient developed symptoms of appendicitis and evidently had a typical case. I was called to consider the surgical aspect of the case with these gentlemen, that is, whether an operation should be performed or not. I found the patient in very good condition, except that there was a great deal of tympany; elevation of temperature slight; pulse nearly normal (84); and expression good. We concluded not to operate since the tympany and other symptoms were becoming less and less marked, but I suggested that the patient be sent to the Infirmary where he could be carefully watched in anticipation of a rupture of the abscess, if one existed. The patient's family agreed to have him sent to the Infirmary, but the next morning when the doctor visited him at seven o'clock, and this early visit was for the express purpose of having him taken to the Infirmary, he found that he had passed a good night; tympany had almost entirely disappeared; so, being so much improved he was not sent out to the Infirmary. He got along well through that day, but sometime during the night was taken suddenly very much worse, went into a collapse and died the next morning at six o'clock.

Dr. A. M. Vance: Up to the time of our last discussion of this subject, in the surgical society, I had never seen a case of appendicitis that I was willing to operate upon, and often wondered why it was we heard of so many operations for this condition in the East, and so few in this section of the country. Since that time I have seen two; one of which I operated upon at the Children's Hospital. The other case I saw in Elizabethtown Kentucky; patient was a young man eighteen years of age; found him in a state of collapse and advised operation at once, but the family refused to allow it with the meagre chances of saving the boy's life that I spoke of. These two cases of appendicitis have come under my observation within the last three weeks, and Dr. Dugan mentions having seen six, every one of which I believe ought to have been operated upon. I believe that every time we can demonstrate the existence of pus, it ought to be let out.

Dr. Turner Anderson: Referring to the third case mentioned by Dr. Dugan: I believe this was a border line case, and I stated at the time if the gentlemen decided to operate I would give my consent; but, at the same time, I remarked that I had seen such cases before and advised delaying the operation until morning.

Now, I do not believe that this was a case of appendicitis at all; I think it was simply a case of rectal abscess, and believe if an operation had been performed without making a rectal examination, a very serious mistake would have been made. The tumor was to my mind too low down

to have been connected with the cæcum.

Dr. W. C. Dugan: I assisted in an operation for this condition a day or two ago, and in this case the tumor was very low down—we were undecided at first whether it was a case of appendicitis or not. When we entered the cavity of the abscess, we found a large amount of pus and some two or more enteroliths, proving beyond all question that it was a case of appendicitis.

I cannot agree with Dr. Anderson concerning the case I saw with him and Dr. Smith. The location of the tumor amounts to nothing. I have seen several cases where there was no tumor to be detected in the iliac region. The appendix is not infrequently prolapsed into the pelvis, and, of course, in such cases the tumor or abscess would be low down. It is my practice in all these cases, to explore the rectum before completing my examination.

WASHING OUT THE STOMACH IN CHLOROSIS.

The *Wiener Klinische Wochenschrift* refers to a communication by Dr. Pick, who publishes the results of some observations he made in Nothnagel's clinic to determine the relation which exists between affections of the stomach and those not infrequent cases of chlorosis in which the leading symptoms are of a gastric character. Some connection between the two has been proved to exist in some cases of pernicious anæmia. The *Wochenschrift* does not consider that Dr. Pick's contribution gives a decided answer to the question, but points out the importance of one result of the experiments. He found, as others have done before him, in all the cases an atonic condition of the stomach, which has not digested the food taken on the previous day, although the patient was fasting at the time of the observation. In these cases Dr. Pick was able to cure the chlorosis quickly by washing out the stomach at stated intervals. In several instances no benefit had been derived previously by treatment with iron. Washing out the stomach prevents abnormal decomposition, which by auto-infection causes the blood dyscrasia. Dr. Pick, with the same object in view, and with equally favorable results, administered creasote when flushing could not be resorted to.—*Lancet.*

BACTERIOLOGICAL NOTES.*

The bacillus coli communis (Escherich) and the bacillus typhi abdominalis (Eberith) identical: Rodet and Roux (*Arch de Med. Exper.* i, 1892, No. 3) have published the results of their further investigations concerning the identity of the bacillus of typhoid fever and the bacillus coli communis. After a large number of inoculation experiments with these bacilli they find that the lesions produced are the same. Rabbits inoculated with these bacilli exhibited the same variation in the temperature, and the development of the experimental disease is the same in both instances. The authors found that there was equally as much variation in the pathogenic effect of one of these forms as in the other when inoculated under different conditions. They feel warranted in concluding from the results obtained that the bacillus of typhoid fever is but a modified form of the bacillus coli communis and that the modification is brought about by pathogenic processes.

[These conclusions are of much interest from a hygienic standpoint and whether or not future investigations will verify them, the facts here recorded are sufficient to cause every practitioner to be zealous to the last degree in urging the correction of bad drainage and other irregularities by which the ordinary intestinal germs may be brought in contact with drinking water or food.]

The virulence of the bacillus coli communis: Lesage and Macaigne (*Arch. de Med. Exper.*, 1892, No. 3) have called attention to some very interesting facts concerning the pathogenic powers of the bacillus coli communis. This organism which is a normal inhabitant of the intestinal canal is found when taken from the healthy intestine to be non-pathogenic excepting when injected in very large doses (more than one cubic centimeter). A diseased condition of the intestine gave to the germ an acquired violence. A diarrhœa produced by a certain drug (tartar emetic) was as effective in rendering the coli germs pathogenic as when its disorder was brought about by other agencies. Under pathogenic conditions this bacillus coli communis acquires its power of penetrating the intestinal wall and at post-mortems

---

* Translated for Medical and Surgical Reporter.

they were found in the various organs of the body. This fact was demonstrated in cases of diarrhœa, cholera infantum, cholera morbus and typhoid fever.

In cases of lung trouble (pneumonia and broncho-pneumonia) the bacilli coli were found in the lung tissue. The author considers that the invasion takes place during the death agony.

The fact of practical value is that when these bacteria acquire violence they exhibit pathogenetic powers in varying degrees. Under such conditions they may cause suppuration, septicæmia and inflammation of the serous membranes. [This work like that of Rodet and Roux emphasizes the importance of proper drainage.]

The treatment of experimental tuberculosis by Koch's tuberculin, Hunter's modification and other products of the tubercle-bacillus: Trudeau (*Medical News* Sept. 3, 1892) has contributed to medical knowledge the results of his experiments with Koch's tuberculin. Hunter's modifications, filtered culture-medium and bacterio-protein. Twelve guinea-pigs were inoculated with pure cultures of tubercle-bacilli. Four were kept as controls, the remainder treated with subcutaneous injections of Koch's crude tuberculin beginning with one milligram daily and steadily increasing to one cubic centimeter. Care was necessary in order not to kill the animals with an over-dose during treatment. The animals all died. The controls in an average of eighty-eight days, the others with an average of one hundred and twelve days. This result differs but little from that of a large number of European investigators. He concludes that Koch's tuberculin does not cure experimental tuberculosis in a guinea-pig although its specific influence on the primary lesions is indisputable. His results with Hunter's modifications led to the conclusion that the modification C. B. (Hunter proposed two modifications which he designates merely as B. and C. B. both of which bring about in lupus certain reparative changes tending to cure) contains less of the remedial principle than tuberculin, and is apparently quite as dangerous. Modification B is as efficacious as tuberculin, and free from some of its dangers.

The author's work upon the effect of the filtrate of liquid cultures and the glycerine extract of the washed bacilli is very interesting. His results show that tubercle bacilli (which have been deprived of all culture liquid by washing them in masses on filter paper with tepid water) have, when extracted with 50 per cent. glycerine and water, an injurious effect; when treated with hot alcohol, a doubtful, and, at best, feeble remedial influence over experimental tuberculosis. They produce suppuration and serious constitutional impairment, which may result in organic disease and death. The filtrate of liquid cultures contains the elements that bring about reaction and cure in tuberculous tissue injections of it experimental tuberculosis in a rabbit's eye was cured but the permanency of such a cure has not yet been established.

A simple method of demonstrating the presence of tubercle bacilli in sputum: Kaufmann (*Centralblatt f. Bacteriologie u. Parasitenkunde,* Bd. 11,1892, p. 142) has published a new method for demonstrating the presence of tubercle bacilli in sputum and tissues. Although the number of methods is already very large the author ventures this one on account of its simplicity which renders it of special value for the busy practitioner. The method differs from those of Wilson, Gabbet and others, in the use of boiling water instead of acids for decolorizing the tissue cells and other bacteria. The method is as follows:

Cover-glasses are smeared with a very thin layer of the sputum or suspected material and allowed to dry in the air, after which they are passed three times film upward through the flame of a Bunsen burner or spirit lamp. The film is then covered with carbolfuchsin and heated in the usual manner over a flame or the cover-glass is floated on the surface of the hot staining fluid in a water glass for from 2 to 5 minutes. After staining, the preparation is washed in water heated to from 98-100° C. for from 1-3 minutes. The peparation may be examined at once in water or previously counter-stained as the examiner desires, the tubercle bacilli will be found to be of a deep red and the tissue cells of a grayish-white color. Care must be taken that the film on the cover-glass is very thin. The method is said to be quite as good for sections. The author does not recommend this method for laboratories but for physicians who do not have the facilities for applying the other methods. The method has also been found to work satisfactorily with the bacillus of leprosy. V. A. M.

HEREDITARY INFECTION.

Translated for The Medical and Surgical Reporter by Marie B. Werner, M. D.

Dohrn (*Deutsch. Med. Wochen.* Sept. 15, 1892) in a paper on "The Question of Hereditary Infection," states, that he has been much interested in the communications of Caspary regarding Fournier's writings, which awakened a desire to enter into the consideration of the above question from the obstetrician's standpoint. He admits that his observations may be deficient, but viewing the subject from a different standpoiut than Caspary, he bases his results upon practical and microscopical investigations. Dohrn sees the patients in the last stages of pregnancy, and the first weeks of the puerperium; he sees and watches the new-born child in the early weeks of its life. The information regarding the health of the father may often be very unsatisfactory. The syphilologist has on the other hand the patient under his care a much longer time, and if he happens to be the family physician has an opportunity of knowing more of the previous family history. He, nowever, fails to have the opportunity of observing the newborn child, as well as the study of the placenta and its membranes, upon which Dohrn places great importance. There is also a lack of opportunity to study the products of abortions of syphilitics. He further believes if the line of study was more equal with both, the conclusions would not be so widely different, Caspary emphatically reaffirms the statement of other syphilologists that the placenta is a medium of infection, while Dohrn takes the opposite view with that of other gynecologists and of Krassowitz the syphilologist.

To prove this he advises careful study of the placenta which shows the two distinct sets of blood vessels the maternal and fœtal, both so distinctly separated that it is impossible to have a direct interchange of the blood, and since all studies have led to the fact that it becomes necessary to have immediate contact with the poison, that there is always a previous abrasion of the protecting membrane or integument, the question naturally arises how can infection take place through the dividing membranes; To fortify this statement Dohrn asserts that in leukæmia of the mother the fœtal blood has been found free from the disease. In such cases he found the fœtal side of the placenta diseased, while the maternal portion was healthy; he explains this in the following manner: In large maternities, such material is not meagre, the women having often cohabited with different men; after having first become impregnated from a healthy man, they have been infected by a syphilitic. Such a fœtus remains unaffected by a syphilitic mother because the fecundated ovum was healthy. On the other hand syphilologists claim that a fœtus may be syphilitic while the mother is free from infection; this is explained by Fournier by a minimal absorption of the poison through the placental membranes, thus producing a certain tolerance, minus the primary initial lesions. Dohrn, however, doubts this, and thinks there is but one explanation, the primary lesion must have been overlooked, in the mother which may have existed on cervix or post-vaginal wall. Dohrn closes his remarks with the following conclusions: Syphilis can only becommunicated to the fœtus through the products of conception, the ovum and sperma being of equal importance.

If the ovum is healthy at conception it will remain unaffected by any later infection of the mother. The syphilitic ovum will not infect the mother during intrauterine life.—If the mother becomes syphilitic it will be only by direct infection: he heartily endorses the statement of Krassowitz that the syphilitic poison will not pass the healthy dividing placental membrane either from fœtus to mother or from mother to fœtus.

Cattani, (*Riforma Med.*, 1892, June 21), the assistant of Tizzoni, recommends the use of *antitoxin for tetanus* and calls attention to the unfortunate results of traumatic tetanus. Dupuytren and Cloquet—fifty cases no recoveries, all died. Legonest twenty-three cases with twenty-one deaths. In the United States 360 cases with 336 deaths. In the Italian Hospital (1886 to 1887) there were ninety cases with eighty deaths, in earlier years eighty-six cases with eighty deaths.

Those cases treated with antitoxin were often grave in character, but also chronic continuous but lighter cases were spoken of by the authors as having ended fatally.

Those cases treated in addition with chloral hydrate, the drug was given in too small doses to produce desired effects. In addition to Cattani's and Tizzoni's recoveries, those of the clinic at Innsbruck must be regarded impartially—the fatal case was placed too late under treatment and received two injections, further, antitoxin is not only regarded as infallible, but its use in early stages always tends to give relief. Antitoxin derived from the serum of the guinea-pig can be used with equally good results as that derived from the dog—proved by the good results of an as yet unpublished case. The divergent results of Brieger and Kitasato among animals can be explained by the unequal strength of the fluids used.

AN ANATOMICAL CRITERION TO DISTINGUISH MALE FROM FEMALE SKULLS.

Prof. Virchow declared two years ago that all the alleged modes of differentiation so far recommended were worthless, but Dr. Thiem–Cottbus (*Arch. f. Klinische Chirurgie,* Bd. 37) lately described what seems a satisfactory craniological criterion of sex.

The os tympanicum forms part of the posterior wall of the glenoid cavity of the inferior maxillary, and also closes in front and below the bony meatus of the ear. It arises perpendicularly from the petrous portion of the temporal bone posteriorly, and turns backward, in the woman at about half the height of the mastoid process, but in the man at a less height. In the male, the bone develops a sharp edge, which divides to form the sheath of the styloid process; but in woman this sharpened edge does not exist, the bone is rounded into a tubercular form, and the fossa is shallower and flatter.

Thus, in the male this fossa-tympanico stylo-mastoidea is small, and the posterior wall of the glenoid cavity extends so deep that it is not possible for the condyloid process to slip over it. In the female, it is so much more spacious that this feature alone will serve to distinguish the crania of one sex from the other; and it also explains the surgical fact that luxation backward of the inferior maxillary is observed only in women.—*Science.*

Abstracts.

CALOMEL AS A DIURETIC.

In an article in the *Ohio Medical Journal,* on the above subject Saul Nickles says that the use of calomel as a diuretic, was revived by Jendrassik. Lately, nearly all the works on therapeutics state that calomel has been found to be a powerfull diuretic in dropsy, but their descriptions of the method of using were imperfect. Jendrassik, in a case of dropsy, gave calomel and jalap and found diuresis followed in two days, greatly relieving the patient. This led to other trials with equally good results. In a very severe case of cardiac dropsy digitalis failed to relieve; Jendrassik then gave calomel and jalap, of each four grains twice daily, four grains on second day, two grains on third day and three grains on fourth day.

The quantity of urine increased from thirty ounces to over ten pints, profuse diuresis continuing until dropsy disappeared.

Jendrassik, then used it in twenty-four cases each of which was relieved, polyuria beginning about the second or third day. He found that salivation was not liable to be produced. Jendrassik tried calomel in healthy individuals; stomatitis and salivation resulted, but no increase of urine; Stintzing used calomel in twenty-seven cases of which twenty-three were dropsical. He concludes that calomel acts more powerful than all other diuretics; its diuretic action is manifested slightly in patients without œdema, but in a very high degree, in cases of dropsy.

The effects are found in cardiac dropsy, whether this be the consequence of valvular disease or cardiac degeneration. Ascites, caused by portal obstruction and dropsy caused by chronic parenchymatous nephritis are less amenable to the action of calomel. The incidental effects diarrhœa, salivation and stomatitis may be prevented, or rendered harmless by suitable prophylactic means. The best dosage recommended by Jendrassik is three grains daily, which should be continued, at least three days. If dropsy does not disappear treatment may be resumed.

Nothnagel, also, tried calomel in numerous cases of dropsy, and found it to be very effective.

Opinions differ as to the mode of action

of calomel. Jendrassik supposed that it increased the resorption of the dropsical fluid, by the blood, and that calomel, does not act like digitalis by increasing the blood pressure.

Stintzing and some others hold that calomel acts directly upon the kidneys, because they found some increase of urine in patients not affected with dropsy. Cohnstein also holds this view.

ÆTIOLOGY OF DIPHTHERIA.

Wilson in the *Indiana Medical Journal* having given special attention to the above subject, arrives at the following conclusions. Diphtheria is caused by a specific germ. It is an acute infectious disease, the bacillus being transmitted from the body in particles of diphtheritic exudation, saliva, and ether secretions of the body. Also, that the poison may be transmitted by direct contact, by inoculation and by inspired air.

The most frequent mode of infection is by contact, with infected substances. The conditions which most favor the development of diphtheria are damp, cold localities, sudden changes of temperature, bad hygiene, depressing influences, and age.

The germs may be found in the mold on the wall paper and in foul, damp places for months after the disease has been present.

He also mentions that animals and fowls may convey the disease.

REPORT OF ONE THOUSAND CASES OF LABOR, WITHOUT A DEATH.

The *Columbus Med. Jour.* publishes the results obtained at the Preston Retreat, Philadelphia, by Dr. Joseph Price. In this series of cases, there were a number of complicated cases which were successfully dealt with, both as regards mother and child. The patients were admitted two weeks before labor and remained four weeks after. On admission they are given a bath, laxative and clean clothing. Until labor begins, two soap-baths are given weekly, bowels kept loose and kidneys are watched. When symptoms of labor begin, a thorough bath is given, an enema is administered, and the vagina douched with a 1–2000 bichloride solution, clean clothing is then applied, and patient put in room for delivery, both nurse and physician make careful toilets and, as a rule, only one examination is made. Only in complicated cases, are repeated examinations made. Only two douches are given, one before labor and one after. In the final douche some of the fluid is thrown over the thighs and external genitals, then a pad is applied, which is changed from four to six times daily. The mothers as a rule nurse their children. They remain in bed usually about eleven days. The infantile mortality is low.

A CASE OF HEALED TUBERCULOSIS WITH AUTOPSY.

Dr. Albert Abrams, in *Occidental Medical Times*, reports the following case —E. I. aet. 27 showed on examination, evidencs of cavity formation and consolidation of both pulmonary apices. There was also dilatation of both ventricles of the heart; irregular and rapid heart action. The sputa contained a very large number of tubercle bacilli.

The diagnosis, pulmonary tuberculosis. The patient was given creosote internally, in drop doses, and increased until a drachm was taken daily.

The pneumatic cabinet was also used daily. There was a gain of twenty-eight pounds in weight in four months. The sputa disappeared and bacilli were no longer recognizable. He then passed from observation and died six months later. The thoracic viscera were examined. The pleura over the apices showed cicatrices, which corresponded with the cavities, the size of walnuts in both apices. The left lung was much retracted, adherent and showed the appearance of interstitial phthisis.

The anatomical diagnosis was "Healed tuberculosis."

He cites this case, to show the value of creosote, in cases where the sputa is full of bacilli.

INJECTION FOR THE TREATMENT OF TUBERCULOSIS OF THE BLADDER.

Dr. Petit (*La Semaine Médicale*, No. 11, 1892) praises the following as an injection in the treatment of tuberculosis of the bladder:

℞

Iodoform	gms. 20.
Glycerine	gms. 10.
Distilled water	gms. 6.
Gum tragacanth	cgms. 20.

Selected Formulæ.

LOCAL ANÆSTHESIA OF THE BLADDER.

To produce local anæsthesia of the bladder inject the following:

℞ Aq. fontan. dist.....f℥jiss.
Cocain. murat.....gr. v-ix.
Sig.—Sufficient for one injection.

—*Il Raccoglitore Medico.*

PRESCRIPTIONS FOR ECZEMA.

Cases of acute eczema should not be treated by liquids, but by powders, according to *L'Union Médicale* of March 29, 1892. The following powder may be used where there is acute inflammation:

℞ Oxide of zinc.....
Subnitrate of bismuth.....āā..℥iiss.
Talc.....℥iss.

In the treatment of chronic eczema it is often wise to commence with ointments of zinc, such as follows:

℞ Oxide of zinc.....gr. xxx.
Vaseline.....℥vi.

Or the following may be employed if the first is not sufficiently active:

℞ Calomel.....from gr. vii to ℥i.
Oxide of zinc .....gr. xv to ℥i.
Vaseline..... ℥vi. M.

In cases which are unusually rebellious, as in the case of those eczemas which are in folds of the body, the following may be employed:

℞ Yellow precipitate.....gr. xv.
Pure oil of cade..... .....gr. xv to ℥i.
Vaseline.....℥vi. M.

This ointment is very active, and is harmful if employed in regions where it can produce folliculitis around hair-follicles, in which case the following may be employed:

℞ Sulphur.....gr. xv.
Coca-butter.....℥i.
Castor oil.....℥i. M.
Sig—A small quantity of naphthol or camphor may be added to this.

In those eczemas with abundant desquamation, the following prescription is useful:

℞ Salicylic acid.....gr. xv.
Oxide of zinc.....gr. xxx.
Vaseline.....gr. xxx.

When pruriginous eczema is present, the following is useful, as it protects the parts:

℞ Oxide of zinc..... ... .
Vaseline, equal parts.....

It may be well to incorporate with these substances, if pruritus is present, a little oil of peppermint or carbolic acid, in the proportion of 1 to 4.—*Ther. Gaz.*

IRITIS.

In certain cases of very painful iritis one may use the following:

℞ Aq. destillat.....gms. 10.
Cocain. hydrochlorat.....cgms. 20.
Homatropin. hydrobromat.....cgms. 30.

Homatropine used alone acts as an irritant and causes a profuse secretion of tears and peri-corneal hyperæmia; the use of cocaine diminishes these phenomena.

A POWDER FOR CORYZA.

℞ Naphthaline in an impalpable powder, ℥vi.
Powdered boric acid.....℥vi.
Powdered camphor.....gr. xv.
Extract of violets.....gr. xv.
Essence of roses.....gtt. xx.
Sig.—Mix and use as a snuff in coryza.

—*L'Union Mèdicale.*

LOCAL ANÆSTHESIA MIXTURE.

The following (*Lo Sperimentale*, No. 18, 1891) is given:

℞ Ether.....gms. 75.
Acid carbolic.....cgms. 30.
For external use. Spray on the part to be anæsthetized.

BRONCHO-PNEUMONIA.

L'Union Médicale for March 24, 1892, gives the following prescription for the treatment of broncho-pneumonia of children in the later stages:

℞ Brandy.....℥ss to ℥i.
Quinine sulphate.....gr. x.
Syrup of orange.....℥ss.
Peppermint-water..... ℥ii. M.
Sig.—Give 6 to 10 coffeespoonfuls of this mixture to a child each day.

INFANTILE DYSPEPSIA.

℞ Cascarilla Tincture.....2 grammes.
Rhubarb Tincture.....4 "
Bitter-orange-peel Tincture, Gentian Tincture, Nux-vomica Tincture } of each, 8 "
For a child of seven, 10–15 drops in water, after meals.

—*Simon.*

HOW TO ADMINISTER THE ETHEREAL EXTRACT OF MALE FERN.

Dr. Crequy (*Lo Sperimentale*, No. 4, 1892) prescribes the ethereal extract of male fern as follows:

℞ Ethereal extract male fern.....gms. 5.
Calomel.....dgms. 8.
Sufficient for fourteen capsules. Two capsules every ten minutes.

This prescription is based upon the fact that the active and toxic principle of the male fern is soluble in fatty oils. Hence castor oil, the common purgative after male fern, should be avoided in the expulsion of tænia by this drug.

Medical and Surgical Reporter

ISSUED EVERY SATURDAY

EDITORIAL AND BUSINESS OFFICES:

29-35 N. Tenth St., Cor. Filbert, Philadelphia.

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, OCTOBER 15TH, 1892.

TAPE-WORMS.

A review of a certain French article on the tape-worms of man, which is now going the rounds of the medical journals, deserves a word of correction. The review states that a French scientist, M. Colin, has recently discovered that the tape-worm which man obtains from beef is identical with the tape-worm obtained from pork and that it is impossible to determine whether a person has become infected from pork or from beef, even by a careful study of the parasite passed by the patient.

These statements, however, are totally false and it seems almost impossible that medical journals should give any credence to such claims, when zoologists have worked the matter out so carefully and have given us so many characteristics by which we can distinguish between the two forms.

The two species in question are known to medical zoologists under the name of *Tænia saginata* ("the beef-measle tape-worm") and *Tænia solium* ("the pork-measle tape-worm.")

The beef-measle tape-worm is contracted by eating the larva (so-called *Cysticercus bovis*) which is found in the muscles of beef, especially in the muscles of the jaws and tongue. The head of this parasite is provided with four suckers *but bears no hooks.* If a mature segment of the worm is compressed between two glass slides and held up to the light, the uterus will be distinguished in the form of a straight stem running longitudinally and giving off numerous (15-30) branches on each side.

The pork-measle tape-worm on the other hand possesses two circular rows of small hooks on the crown of the head, as well as four suckers, similar to those found in the beef-measle worm. Upon compressing a segment between two glass slides it will be seen that the uterus possesses but 8–12 branches on each side.

With the aid of a microscope it is also possible to notice distinct differences in the size and shape of the eggs produced by the two worms.

The statement that M. Colin claims that both hogs and cattle are infested by the same species of larva is easily explained.

Under normal circumstances, the larvæ found in the muscles of hogs, possess the double row of hooks on the head. Occasionally, however, the hooks fall off and a larva is obtained which resembles very closely the larvæ found in beef, which as stated above, are never armed with hooks. M. Colin evidently had one or more of these degenerated larvæ before him when he made his statement that the two forms were identical,

It may possibly occur to some physicians that it is immaterial whether a man has the beef-worm or the pork-worm; but such is not the case, since the pork-worm is much more dangerous than the beef-worm. If a patient harbors the armed form he is not only subjected to the inconveniences arising from the presence of a parasite in his digestive tract, but he is constantly in danger of re-infecting himself with the eggs of the worm. The eggs of the parasites are present in the fæces and may, by various means, be transferred to his food and thus to his mouth. Upon arriving in his stomach the egg-shell is destroyed and a six-hooked embryo is set free. This embryo then bores its way through the intestinal wall and wanders to some muscle, to the inside of the eye or even to the brain, and develops into the larval form (*Cysticercus cellulosæ*) the same as it would do in the muscles of hogs.

The embryo of the beef-measle worm, on the other hand, cannot develop into a Cysticercus in the human muscles, and a man may swallow any number of the eggs with perfect impunity.

From this it will be seen that the physician should know whether his patient harbors the beef-worm or the pork-worm. If the latter is present, it should be removed immediately in order to prevent infection with the larvæ; further, if this worm is passed, the physician should be very careful in handling it as he may infect himself with the ova. The other worm, however, can be handled without fear of infection.

The infection of human muscles by *Cysticercus cellulosæ* (pork-measles) is not at all uncommon in Europe, but fortunately it is very rare in this country, since the adult parasite itself is of rare occurrence in America.

The tapeworm which is most frequently found in America is *Tænia saginata.*

These two species are not the only tapeworms found in man. *Bothriocephalus latus* (the broad Russian tape-worm) is obtained from fish. This parasite is very frequent in Russia, but has been recorded only four or five times in this country. *Bothriocephalus cordatus* and *Bothriocephalus liguloides* are two other species which are supposed to come from eating larvæ in the muscles of fish. *Hymenolepis nana* is an extremely small tape-worm which is quite frequent in Italy, but has been recorded but twice in the United States. *Hymenolepis diminuta* (*Tænia flavo-punctata*) is a small tape-worm of rats, which is occasionaly found in men. *Dypilidium caninum* (*Tænia cucumerina*)is a common tape-worm of dogs, which is now and then found in children. The larval stage of this worm lives in the fleas of dogs, and children become infected with the parasite by swallowing, consciously or unconsciously, fleas containing the larvæ.

The presence of a tape-worm can be definitely diagnosed by finding the loose segments in the stools, but if any doubts exist as to the presence of the parasites, any expert microscopist can settle the question by a microscopical examination of the fæces.

EXOPHTHALMIC GOITRE.

In a case of exophthalmic goitre, Dieulafoy gave the following prescription, as there was a distinct tendency to hæmoptysis:

℞ Powdered ipecac.....gr. ½.
Powdered digitalis-leaves.....gr. ¼.
Extract of opium.....gr. 1-10. M.
Sig.—To be made into one pill. From four to six of these pills may be given in twenty-four hours.

The effect of this medication is a decided moderation in the symptoms and general improvement in the condition of the patient. Should diarrhœa follow the administration of ipecac in these constant doses it may be guarded by increased doses of opium.

CHAPPED HANDS.

WASH.

℞ Green soap.....1 part.
Compound Benzoin Tincture.....4 parts.
Glycerin.....8 "
Rose Water.....16 "

—*Wendel.*

Book Reviews.

R. Blanchard. Sur les Œstrides Americains dont la larve vie dans la peav de l'Homme (Ann. d. l. Soc. entomol. d. France, 1892. pp. 109–154).

Blanchard has brought together a large number of cases of œstrus-larvæ, found under the skin of man; he further figures and describes ten larvæ in his possession which were taken from man. His general conclusions are that four American species of Œstrides belonging to the genus *Dermatobia* attack man, but all of these are found in animals as well, so that we have no right to speak of the species *Dermatobia* (or *Œstrus*) *hominis*.

The four species in question have been described under the names:

1. Ver macaque=*Dermatobia noxialis.*
2. Torcel=*D. sp.* (*?*)
3. Berne=*D. cyaniventris.*
4. Ver moyocuil=*D. p.*(*?*)

BOOKS RECEIVED.

Contributions of Physicians to English and American Literature, by Robert C. Kenner, M. D., The Physician's Leisure Library, Geo. S. Davis, Publisher, Detroit, Mich. Price 25 cents.

Cardiac Outlines For Clinical Clerks and Practitioners and First Principles in the Physical Examination of the Heart, for the Beginner, by William Ewart, M. D. Cantab, F. R. C. P., Physician to St. George's Hospital; Clinical Lecturer and teacher of Practical Medicine in the Medical School; Physician to the Belgrave Hospital for Children; Additional Examiner in 1891, for the third M. B. of the University of Cambridge; Late assistant Physician and Pathologist to the Brompton Hospital for Consumption and Diseases of the Chest. With sixty-two illustrations. New York: G. P. Putnam's Sons.

Hydrotherapy at Saratoga, a treatise on natural mineral waters, by J. A. Irwin, M. A., Cambridge, Eng.; M. A., M. D., Dublin University; L. M. Coll. of Physicians, Ire.; Member of the Royal College of Surgeons, Eng.; Member of the British Medical Association; Fellow of the London Obstetrical Society and the New York Academy of Medicine, etc.; formerly house surgeon, Royal Free Hospital, London; Shropshire and Montgomeryshire Counties Lunatic Asylum, and Physician to the Manchester Southern Hospital for Women and Children. New York: Cassell Publishing Company.

A Manual of the Operations of Surgery for the use of Senior Students, House Surgeons and Junior Practitioners; illustrated; by Joseph Bell, M. D., F. R. C. S. Edin., Consulting Surgeon to the Royal Infirmary and Surgeon to the Royal Edinburgh Hospital for Sick Children. Seventh Edition, Revised and Enlarged. Edinburgh: Oliver and Boyd, Tweedale Court. London: Simpkin, Marshall, Hamilton, Kent & Co., Limited, 1892.

Essentials of Diagnosis arranged in the form of questions and answers, prepared especially for students of medicine, by Solomon Solis-Cohen, M. D., Professor of Clinical Medicine and Applied Therapeutics in the Philadelphia Polyclinic; one of the physicians to the Philadelphia Hospital, etc., and Augustus A. Eshner, M. D., Instructor in Clinical Medicine in Jefferson Medical College, and in the Philadelphia Polyclinic; Registrar in the Neurological department of the Philadelphia Hospital, etc. With fifty-five illustrations some of which are colored, and a frontispiece. Price $1.50 net. Philadelphia: W. B. Saunders, 913 Walnut St., 1892.

Temperament, Disease and Health, by French Enser Chadwick, Commander U. S. N. New York: G. P. Putnam's Sons.

Book on the Physician Himself, and things that concern his reputation and success, by D. W. Cathell, M. D. New Tenth Edition (Author's Last Revision). Thoroughly Revised, enlarged, and rewritten. In one handsome Royal Octavo volume. 348 pages. Bound in Extra Cloth. Price, post-paid, $2.00, net. Philadelphia: The F. A. Davis Co., Publishers, 1231 Filbert Street.

The Medical and Dental Register–Directory and Intelligencer of Pennyslvania, New Jersey and Delaware (1892 Edition): pp. 424; price, by mail, $1.25. George Keil, Publisher, 306 Chestnut Street, Philadelphia.

Periscope.

THERAPEUTICS.

THE TREATMENT OF MIGRAINE.

Dr. Savigny believes that the etiological conditions must be considered. Those predisposed to this disease are the neuropathics, gout, rheumatics, diabetics, and anæmics. Constipation is an important adjuvant condition. The use of narcotics (morphine hypodermatically) is objectionable, in that it causes vomiting, is only palliative and not curative, and increases the constipation. Chloral only fulfils a symptomatic indication. The analgesics, salicylic acid, antipyrine, exalgine, acetanilide, and indeed sulphate of quinine, yield cures, but often relapses quickly follow.

Haig, believing that in gouty subjects there is a connection between this and an increased excretion of uric acid, uses large doses of citric or nitro-muriatic acid. He believes that antipyrine acts in the same way. A nitrogenous diet, meat, cheese, and beer, should be forbidden. By its chemical acid the good effects of chloride of soda are explained (Batom, Nothnagel, Rabod;) this, however, has been useless if there exists a gastralgia. The treatment between the attacks may be the reduction of obesity (method of Oertel), hydrotherapy, total rest, physical and intellectual, before a cold bath, with physical exercise afterward, or if the bath is a hot one, followed by rest (procedure of Pelezeus). For the attack itself, Dunn has used co-

caine hypodermatically, although it often causes insomnia, agitation, exaggerated reflexes, rapid pulse, palpitation. Rossbach believes in the value of local massage. Neftel uses hot water to increase transpiration, muscular exercise, improvement of the general condition. Morris Lewis uses ten drops of the tincture of eucalyptus four to six times daily, while Gill Wylie has prescribed with success a grain of ox-gall and a drop of essence of gaultheria six times daily. The author employs caffein and bromide of ammonium in peppermint water, every two hours during the attack, recommending, in addition, electricity, either static or galvanic, with general faradization.—*Revue de Thérapeutique Médico-Chirurgicale*, 1892, No. 4, p. 94.

STRONTIUM SALTS IN BRIGHT'S DISEASE

At a recent meeting of the Therapeutical Society, M. Constantin Paul reported on the use of strontium lactate in the treatment of albuminuria. The lactate is the salt preferred, and it is made by dissolving strontium hydrate in lactic acid, sufficient water being added to assist solution, which should be brought to a state of neutrality by adding the strontium hydrate to saturation. The pure lactate (which gives no precipitate with potassium chromate) has been given in daily doses up to 8 or 10 grammes to adult males without danger. Although not diuretic, it diminishes the quantity of albumin and generally ameliorates the symptoms. This has been specially noted in rheumatic parenchymatous nephritis, in the albuminuria of gouty or scrofulous subjects, scarlatina patients, and that which is common before and after confinement. He added that the best time to begin the administration of strontium lactate is when the secretion of urine is scanty and there is a tendency to uræmia. In the course of the discussion Dr. Dujardin-Beaumetz stated that the bromide of strontium was more easily supported by the stomach than other alkaline bromides. M. Patein stated that yellow chromate precipitates 1 milligramme of chloride of barium in 20 grammes of water, but it also precipitates salts of strontium when they are not in a very weak solution, hence errors might arise. Bichromate of potash, on the contrary, will detect a solution of $\frac{1}{2000}$ gramme of a salt of barium, but does not affect strontium salts. The method of procedure which he suggested was to make a saturated solution of the salt and add two or three drops of bichromate solution; the liquid should remain clear even after twenty-four hours. Or, make a weak solution of the strontium salt and add two or three drops of solution of neutral chromate; the liquid should remain clear for some minutes. M. Patein added that he found the salts of strontium sold to be generally impure. Dr. Dujardin-Beaumetz expressed his pleasure at this statement; the tests he considered to be very important.

A CHEAP DISINFECTANT.

Nitrate of lead is the cheapest disinfectant known that fulfils its intent. It does not, however, prevent putrefaction. The chloride of lead is much more effective in all directions. It is made by dissolving a small teaspoonful of the nitrate of lead in a pint of boiling water; then dissolving two teaspoons of common salt in eight quarts of water.

When both are thoroughly dissolved mix the solutions. When the sediments has settled you have two gallons of clear fluid, which is a saturated solution of chloride of lead in water. A pound of nitrate of lead will make several barrels of the liquid and cost from eighteen to twenty-five cents retail.—*Annals of Hygiene*,

---

PYRAZOLE.

H. Tappeiner (*Centralblatt fur. klinische Medicin*, No. 46.) has found that this substance possesses peculiar properties which may be used to advantage in certain forms of nervous disease. Given in large doses it is a paralyzer of the nervous centre. As a heart stimulant its action is prompt. That it is an excitant of the secretory apparatus of the kidney is shown by the active diuresis following its administration. Aside from these conditions produced by pyrazole, the physiological action is very similar to that of antipyrine. The dose is from one-half grams. No nausea, vomiting or other unpleasant sensations have been observed to follow its employment.

ATROPINE AS A HEMOSTATIC.

Dmitrieff (*Wratsch*, 1891, No. 50) reports the successful employment of atropine as a hemostatic in two cases of metrorrhagia. In one case the hemorrhage per-

sisted, despite the employment of the usual remedies, including the tampon; but ceased after injections each of gr. $\frac{1}{24}$ of atropine. The second case occurred in an anæmic woman, who became syncopal, with cold extremities. The first injection was followed by improvement, and the third by cessation of the bleeding. In both cases the pupils were slightly dilated.—*Wiener medizin Presse*, 1892, No. 16, p. 639.

METHYL-VIOLET IN MALIGNANT TUMORS.

Nanu has obtained very good results in ten out of twenty-five cases of malignant tumors by injecting methyl-violet according to the system of Von Moorhof. The diagnoses were confirmed by microscopic examination. On the other hand, Torrie after a trial of this method in several cases came to the conclusion that it is never of any benefit and may be harmful.

SULPHUR IN CHLOROSIS.

Professor Schultz again draws attention to the value of sulphur in certain cases of anæmia. After alluding to the prominent part played by sulphur in the life of the cell—a part analogous to that of hæmoglobin in the blood—and to the excellent results obtained by the use of sulphur waters in malarial cachexia, he comes to these conclusions:—(1) In cases of pure chlorosis in which the iron proves inefficient, the general condition is decidedly improved by sulphur; (2) after the administration of sulphur has gone on for some time, treatment with iron can be commenced and continued with success; (3) in cases of chlorosis complicated with catarrhal and inflammatory conditions of the digestive tract, sulphur is not borne. Schultz relates a case illustrating the advantage of the sulphur treatment. The patient, a woman 34 years of age, showed an extreme degree of anæmia, and had loud cardiac bruits. She complained of headache, giddiness, shortness of breath, palpitation, and complete loss of appetite, with pain in the epigastrium after food. Rest in bed with bland fluid diet was ordered, and this—with bismuth and morphine and occasional doses of Carlsbad salt—relieved the gastric pain. Iron was tried in the form of the saccharated carbonate, but vomiting immediately set in, and it had to be discontinued. Other preparations of iron were tried with no better result. Sulphur was accordingly given, and this she bore very well. Great improvement ensued; the anæmic appearance lessened, and the headaches and palpitation disappeared. She was discharged from hospital greatly bettered; but she still complained of some palpitation on exertion. Iron was again given as the saccharated carbonate, and this time was tolerated without difficulty. The sulphur was used in the form of flowers of sulphur mixed with sugar of milk, as much being taken three times a day as would lie on the point of a knife.—*Berliner klin. Wochenschr.*, No. 13, 1892.

LUECKE'S METHOD OF TREATING ERYSIPELAS.

Winkler (*Wiener med. Wochenschrift*, No. 46–48, 1891) writes that the method of Luecke consists of the application of rectified oil of turpentine with a brush or small compress with stroking movements from the healthy toward the diseased portion several times daily; the séances should not exceed five in the twenty-four. In the after-treatment following each séance, the parts are covered by cotton wadding held in place by a bandage. The parts are thoroughly cleansed in the beginning with ether or alcohol. Excoriations are covered with sublimated lanolin. Twenty-two cases are reported, showing an average of five days elapsing between the first application and the desquamation marking the subsidence of the disease. The benefit derived is said by the author to depend upon the ozone present in the oil of turpentine.

TREATMENT OF ENTERIC FEVER.

Mason (*Boston Med. and Surg. Jour.*, Nos. 14 and 15, 1892), has published a report on 676 consecutive cases treated in the Boston City Hospital. Favorable results were obtained from the use of hydronaphthol, though relapses were not prevented. In a series of 103 consecutive cases, forty-five were treated with hydronaphthol and fifty-eight without. In twenty-seven of the forty-five cases diarrhœa diminished or ceased, but in some this effect was not produced for two weeks. Four cases relapsed, and two died. Of the fifty-eight treated without hydro-

naphthol, six relapsed and seven died. Hæmorrhage from the bowel did not occur in any cases treated with hydronaphthol, but did occur in three of the others. In the hope of preventing relapse, thirty cases were treated with the drug at first every two hours, later every four or six hours, from the time of the admission until convalescence was well established. Two cases, however, did relapse, and one died with symptoms of perforation. From a comparison of his statistics (676 cases) with Hare's (1173), Mason arrives at the conclusion that the general mortality might be reduced two per cent. by the systematic use of cold baths, and that this diminution would be effected mainly by a decrease in the number of deaths among women. Women offer a feebler resistance to pyrexial exhaustion, and it is in preventing this exhaustion that the bath method has its chief effect.—*Brit. Med. Jour.*

HÆMOSTATIC VALUE OF SHEPHERD'S PURSE.

This has been known for a long time, but was temporarily lost sight of. The drug has, however, been resurrected, and much testimony as to its efficiency in uterine bleeding is being adduced. Shepherd's purse loses much of its efficacy in drying, so that only the fresh herb or a fluid extract prepared from the latter should be employed. As a styptic Von Oefele considers this fully equal to hydrastis, with the advantage of cheapness and absence of bitter taste. A single dose of the green fluid extract should not exceed fifteen grams, the maxim total dose for twenty-four hours being thirty grams.

MEDICINE.

PARALYSIS OF THE BRACHIAL MUSCULO-CUTANEOUS NERVE.

Windscheid describes (*Neurol Centralbl.,* the case of a man who noticed a sensation of numbness in his right thumb and part of the front of the forearm, with partial inability to bend the elbow, a few hours after carrying a heavy marble slab on his right shoulder, a sharp edge of the slab having pressed deeply into the supraclavicular fossa. At examination a fortnight later the forearm could be voluntarily flexed, but, when bent, the biceps remained flaccid and uncontracted; numbness and formication were felt in the volar portion of the thumb and the radial side of the fore-arm; in the same regions analgesia was almost complete, though contact impressions were fairly well perceived; there was no ordinary reaction of degeneration. Indirect faradic stimulation of the affected biceps elicited "Rumpf's traumatic reaction" very clearly. On cessation of the tetanizing current a wave of short contractions appeared in the muscle. This phenomenon was discovered by Rumpf in cases of traumatic neurosis, and was considered by him to be an important objective indication of that affection. He observed it in various nerve territories besides that of the nerve primarily excited. In Windscheid's case it was limited to the biceps, and was not obtained on direct stimulation of the muscle. The sign, in Windcheid's opinion, has not the value accorded it by Rumpf; it partially resembles Ritter's opening tetanus. In the case above referred to it could only be regarded as an indication of increased excitability of the nerve below the injury. After three months treatment with electricity the biceps contracted well, the sensory disorders were diminished, and Rumpf's reaction was less distinct.—*Brit. Med Jour.*

CEREBRAL SYPHILIS.

Cnopf (*Münch. Med. Woch.,* March 15th, 1892) relates the case of an infant, thirteen weeks old, which, in addition to the ordinary symptoms of intestinal catarrh and atrophy, had severe attacks of pain, during which the neck and back muscles became rigid. Eight days before death there were convulsions. At the necropsy there was a circumscribed greyish-red gelatinous mass in each corpus striatum. On the left side the centre was yellow and breaking down. The occipital lobes were sclerosed. There was external and internal hydrocephalus (*hydrops e vacuo.*) There was no change in the vessels. The other organs were healthy. The author shows by statistics that cerebral syphilis in children is rare. He had only been able to find twelve recorded cases. In one-half there was disease in the arteries and in one-half gummata. These gummata occurred mostly in the base of the frontal lobe, partly as yellow-

ish centres of softening and partly as calcified masses. In one case the brain was atrophied and sclerosed. Only four of the twelve cases occurred under one year of age. Although the parents of the infant appeared quite healthy, it was ascertained that the father had syphilis eight years previously, for which, however, he was thoroughly treated. Most of the twelve cases had external manifestations of syphilis as well as cerebral symptoms. Among the latter were noted nystagmus, dilatation of one pupil, diplopia, optic atrophy, swelling of the optic disc, chloroiditis, loss of smell and hearing, hemiplegia, anæsthesia, paralysis of single nerves, mental symptoms and fits. In the author's case there was no external evidence of syphilis, and no symptoms which could be put down exclusively to cerebral disease. The author then refers to the difficulty of diagnosing cerebral syphilis from other forms of cerebral disease, and yet the diagnosis is essential owing to the importance of early treatment.—*Brit. Med. Jour.*

SOME ANOMALIES OF THE CRANIA OF THE INSANE.

Bianchi and Marimo have examined over a thousand skulls of insane persons. Among their conclusions are the following: They believe that cranial anomalies are, perhaps, more dependent on the locality from which the persons came than on the diseases or the degree of intelligence of the individuals. In so-called degenerative forms, purely bony anomalies related to cerebral development are more rare than in psycho-neurotics. There is no direct relation between insanity and cranial anomalies, but these are much more common in the skulls of the insane.

MEDICAL EMERGENCIES.

The *American Practitioner and News* publishes the following list of medical emergencies, which are all worthy of noting.

Accidents in giving anæsthetics.—Tincture of digitalis hypodermically; draw out the tongue and see that respiration is not mechanically impeded; invert the patient quickly and temporarily; use forced respiration promptly, apply external warmth and stimulation; avoid the exhibition of alcohol.

Angina Pectoris.—Inhalation of chloroform, or a few drops of nitrite of amyl; 1-100 grain of nitro-glycerine, internally; placing the feet in hot water; mustard to the precordial region; dry cup between the shoulders; hypodermic injections of morphine and atropine; administrations of stimulants and anodynes.

Apoplexy.—Elevate the head and shoulders; if pulse is moderately strong and the brain congested, bleed from the arm freely, sixteen ounces or more; eleterine (one-sixth grain) or croton oil, two drops in a drachm of sweet oil or glycerine; cold to the head by means of an ice bag.

Asphyxia.—In drowning, hold the patient's head downward for a few seconds. In hanging or choking, bleed from the jugular. If there is obstruction to passage of air through the mouth or nose, open trachae. Artifical respiration at once and to be continued. Friction, warmth, warm bath (100°), ammonia to nostrils, galvanizing of phrenic nerve.

Asthma, Spasmodic.—Hypodermic of atropine into the nape of the neck; inhalation of smoke of stramonium leaves; fluid extract of nux vomica, internally alcohol, ether, chloral, opium; inhalation of chloroform cautiously administered.

Colic, Gall.—Morphine, hypodermically; inhalations of chloroform; hot applications to the abdomen.

Coma.—Dark room; head high and cool; head shaved; low diet; croton oil; if due to compression antiseptic trephining; if due to anæmia, philocarpine and hot baths.

Heat Stroke.—Remove clothing, sprinkle with water, cold cloths to the head, hot cloths to feet; antipyrin; bleeding in robust subjects. After temperature is reduced give alcohol and diffusible stimulants, hypodermically if necessary.

Pulmonary Hæmorrhage.—If severe, raise the thorax, administer opiate; gallic acid, fifteen grains, every fifteen minutes; ergotin, five to ten grains hypodermically, two or three times daily; ice bags to the chest; as a last resort a ligature may be thrown around the larger limbs. (Tyson).

Hæmorrhage From Stomach or Bowels.—Tannic acid, ten to fifteen grains, if due to capillary oozing. If from typhoid fever or ulcer of the stomach, treat as for pulmonary hæmorrhage.

Hiccough.—Acid drinks, cold douches, ether or chloroform internally, externally

or by inhalation; musk, opium, antispasmodics.

Hysteria.—Inhalations of ether or chloroform, for the spasms. If this is contra.indicated, give mono-bromide or camphor, musk, valerian, assafetida, the bromides. In convulsive seizures, morphine and atrophine hypodermically.

Shock.—Warmth; hot water bottle to feet, flanks and epigastrium; warm effusion to head; horizontal position; frictions, stimulants, brandy, ammonia, galvanism to precordia.

Strangury.—Vesical, hypodermic injection of morphine, to be followed by other remedies; rectal enemata of starch water and laudanum, followed by a hot sitz-bath.

MONSTROUS HYPERTROPHY OF THE PROSTATE.

Dr. Adler presented at the Freie Verein der Chir., in Berlin, the following history: A patient of sixty-six years had for fifteen years suffered from difficulty in urination, but had used the catheter without trouble until recently, when severe bleeding was occasioned by its introduction. Suprapubic and, subsequently, perineal cystotomy were done, but no permanent relief was afforded. The blood oozed from the prostate as from a sponge. The Paquelin cautery was employed, but death soon took place. The prostate measured 6½ centimetres wide and 20 centimetres long.

INSOMNIA OF ALCOHOLISM.

Krafft Ebing speaks very highly of methylol as a hypnotic in this condition. It is employed hypodermically in doses of fifteen minims of a ten per cent. aqueous solution, from one to three times in twenty-four hours.—*Med. Record.*

SURGERY.

A NEW ANTISEPTIC.

Professor Emmerich of Munich has introduced a new antiseptic substance named oxychin aseptol, which he claims will prove fatal to the pus coccus (*staphylococcus pyogenes aurus*) in 0·3 per cent. solution. The drug should be of value in the treatment of gangrene and other putrefactive diseases, and being cheaper than carbolic acid, may be worthy of trial as a substitute for the latter agent.

THE SCHWALBE TREATMENT OF HERNIA.

Steffen (*Correspondenzblatt für Schw. Aerzte,* xxii., No. 2) discusses the report of Heidenthaler in regard to the results obtained in Billroth's clinic in the treatment of herinæ by the method of Schwalbe. He says the poor results are due: 1. To the shortness of the treatment. 2. To the fact that the injections were made without sufficient intervals intervening, and therefore produced an acute inflammation and inflammatory products that were easily absorbed. 3. They were too few in number and too near together. The treatment is one more applicable to private practice and dispensary work, where patients can be under treatment for a long time with long intervals between the injections, producing a chronic inflammation with the production of connective tissue, than it is to hospital practice where the patient occupies so much time and where the methods of Macewen and Bassini produce quicker results. He describes his own method of procedure, with which he obtained favorable results with the treatment of Schawlbe. —*Amer. Jour. Med. Sci.*

A NEW METHOD OF PRODUCING LOCAL ANÆSTHESIA.

Dr. Wiesendenger describes in the *Jour. fur Zahnheilkunde* a new method of producing anæsthesia by the application of cold, the characteristic feature of which is not the cold-producing agent which touches the desired part, but a metallic tube or chamber which is cooled by carbonic acid. The cold may, according to the requirements of the case, be regulated from the temperature of cold water to one sufficiently low to cauterize. The first symptom of this artificial cold is anæmia of the cellular tissue, producing a slight sensation of burning, which is followed by anæsthesia, which lasts from one to two minutes and then disappears without any ill effects.

As the instrument may be manufactured of almost any shape, it is evident that this new method may be used for a variety of purposes. The simple turning of a tap will regulate the stream of carbonic acid to any degree of temperature down to 4° F. No moisture is produced. In using this cold for the purpose of cauterizing, the surgeon has the advantage of producing anæsthesia at the same time. When

applying it to any of the internal cavities, such as the mouth, it is necessary to have the parts carefully dried, as the tissues would otherwise adhere to the instrument. Dr. Kummel applied the method in the case of a boy in the Maria Hospital at Hamburg with such complete success that the boy looked on without moving a muscle while a deep incision of twelve centimetres in length was made in his thigh.

Other gases which can be brought into a fluid state may be used in place of carbonic acid. The carbonic acid which has been used for purposes of anæsthesia may be led into a vessel which has been tested to a pressure of three atmospheres, and is provided with a manometer and safety-valve, whence it could be used as an agent for preserving food. An iron bottle of fluid carbonic acid at a pressure of fifty atmosphere is sufficient for fifty operations. This can be bought for four or fives hillings. The instrument for the application of cold to the tissues costs thirty shillings.—*The Lancet.*

OPERATIVE TREATMENT OF PES TALUS PARALYTICUS.

Eugène Rochard (*Rev. de Orthop.*, employs two methods: The shortening of the tendo Achillis by excision of a portion of the same or by an oblique incision and attaching both portions to each other, followed by the transplantation of tendons by the blending of peronei with the insertion of the tendo Achillis. The shortening of this tendon by Walsham's and Willet's method was almost completely successful in seven cases; in no case was there a complete failure. However, the period of observation was not long enough in these cases. Gibney by oblique separation reached quite excellent results in seventeen cases—in eight cases, satisfactory results,—and in but three cases was he unsuccessful. Kirmisson also obtained a good result in a similar case. The author modifies the latter process by adding a lateral freshening to the simple lapping over each other of the separated parts of the tendon, thus increased chances of union with shortening being offered. Which of these methods is to be preferred is to be determined by a careful examination of the individual muscles. If the gastrocnemius, plantaris and soleus are only atrophic and not completely paralyzed, the anomaly being exclusively caused by an exceedingly strong tension of the tendo Achillis, simply shortening is to be recommended. But if the muscles are completely paralyzed,—which, however, occurs but rarely, it almost without exception following infantile paralysis—the transplantation of tendons is to be employed in order to connect the peronei. Arthrodesis is to be employed only clear cases of dangle foot. The good results of the operation are, of course, lessened by secondary changes in the plantar arch by retraction of the plantar fascia, etc. *A priori*, however, the idea (Fayette Judson) that a weakened muscle must not be allowed to act as it may be injured thereby is to be abandoned.

GENERAL RESULT OF REMOVAL OF TUBES AND OVARIES.

Dr. Wharton Sinkler has given some interesting facts as to the effect of the removal of these organs. In first place, he claims it unjustifiable to remove these organs for the relief of neurasthenia and hysteria where marked disease is not found. It is an undoubted fact that cases of neurasthenia have been cured where even structural changes in the ovaries have taken place. And again, it is the fact that patients are, in some cases, more nervous after than before operation. It is claimed that cures have resulted in epilepsy and insanity, particularly in those cases associated with pain and aggravation of symptoms at the menstrual period, and, as well, these diseases have followed operations. Gain in flesh is marked only where the operation has been performed for pus tubes, etc. Growth of hair on the face, change of voice and acquirement of masculine traits are very rare. Sexual appetite and faculty for the enjoyment of same unchanged, though it must be said that in time(year) it seems to diminish, which may be by the natural result of age.—*Annals of Gyn. and Ped.*

COMPOUND ELIXIR OF IODINE.

This is the name suggested by Wm. Pepper, M. D., (*University Med. Magaz.*, Feb., 1892, p. 376) for a preparation made by dissolving phosphorus, 1-100 grain, and iodide and bromine, each, $\frac{1}{6}$ grain, in one drachm of simple elixir. It has been used with considerable satisfaction in cases of torpid circulation with subacute gastric catarrh, and of subacute

bronchitis with a relaxed and atonic state of the system. An elixir of balsam or of white pine may be used as the solvent, to which the name of *Compound elixir of pine* might be appropriate.—*Amer. Jour. Pharm.*

INTUBATION OF THE LARYNX.

Schmiegelow reports four cases of intubation for croup with three deaths (in a child aged eight, from acute paralysis of the heart; in a child aged nine months, from descending of the diphtheritic process; in one aged eleven months, from pneumonia), and one recovery, in a child aged three.

Schmiegelow performed intubation in eight cases of chronic stenosis, six of which were cases where there was difficulty in getting rid of the canula after tracheotomy, while one case was that of a man, aged twenty-four, who had contracted, as a child, a cicatricial stenosis of the trachea from tracheotomy, and who had at times difficulty in breathing; one was a case of aphonia spastica. The author advocates intubation (1) in cases of acute stenosis due to edema of the larynx; or (2) to diphtheria, when the asphyxia is so developed that there is no time for tracheotomy; or (3) when permission to do the latter operation cannot be obtained; (4) in cases of paralysis of the abductors or spasms of the abductors; (5) in cases of foreign body in the larynx; when there is no time for tracheotomy; (6) in cases of acute stenosis from thyroiditis; (7) all cases of chronic stenosis.—*The Satellite.*

THE TREATMENT OF HÆMORRHOIDS.

At a meeting of the Medical Society of London, Lauder Brunton dwelt upon the influence of cold and over-eating in the development of hæmorrhoids. Mercurials, followed by mild salines, are useful in preventing hepatic congestion. Aloes, in large doses, may conduce to the development of hæmorrhoids by over-stimulation of the muscular coats of the rectum. Small doses, on the contrary, exert a beneficial influence. Hepatic congestion due to cold may be relieved by the application of hot water bags to the nape of the neck and over the liver. Patients subject to hæmorrhoids should accustom themselves to emptying the bowels at night, so as to secure rest in the recumbent posture. When there is much irritability at the anus it is preferable to use a soft sponge and water instead of paper more or less harsh. A pledget of animal wool dipped in hamamelis and introduced into the rectum will act as a mechanical support and as an astringent. In obstinate cases an anal pad may afford great relief.—*Med. Progress.*

THE PATHOGNOMONIC SIGNS OF PERFORATING APPENDICITIS.

Dr. Simon Baruch (*Med. Record*) emphasizes the point that symptoms of shock, carefully looked for, may always be found in perforating appendicitis. These are as follows: the countenance is anxious, the finger-tips, nose and ears are cool; pulse and respiration are out of proportion to temperature, the right inguinal region is very tender, the patient usually lies with the right leg drawn up. Guided by them, Dr. Baruch opposed the views of an experienced physician in one case, insisting upon the operation; and in another did not approve of the operation advised by an experienced surgeon. In both cases his reliance on these pathognomonic signs proved useful to the patient. On the ground of his own experience, as well as that of others, the author urges that when performing appendicitis is diagnosed, either positively or probably, an immediate operation to remove the exciting cause is as imperative as ligation of the vessel in hæmorrhage.

The fact that laparotomies are now constantly performed, under strict asepsis, with absolute safety, should induce the attendant to clear up a doubtful diagnosis of perforating appendicitis by an operation before septic peritonitis forbids it.

OBSTETRICS.

CHLORATE OF POTASH IN HABITUAL ABO RTION.

E.S. McKee in *American Practitioner and News* says:

I have had some noteworthy results in repeated abortions from the use of chlorate of potash. In one case where the patient had aborted ten times while married to two different husbands, fifteen grains of chlorate of potassium were given three times a day; also tr. ferri chloridi, and two children were brought to term and

born alive. No cause could be found in this case, but from the history and the time of the occurrence fatty degeneration of the placenta was suspected. The use of this remedy was first suggested by Sir James Y. Simpson, who employed it on the theory that an abundance of oxygen was supplied to the fœtus by this means through the placental tufts. He gave it because of disease of the placenta, but also believed that it was a means of arterializing the blood. He was led to the use of this remedy by the experiments of Davy and Stephens, who found that an alkaline salt when brought into contact with the blood gave it an arterial appearance. From the large amount of oxygen contained in each atom of the chlorate of potash, Simpson argued that the maternal blood would be better oxygenated, and the child's respiration thereby improved by its administration. Anæmic patients improve in color under this drug.

Alkalies are promoters of waste and assist the removal of inflammatory products. Patients who had not gained under tonics and nutrients will improve in weight and strength upon the withdrawal of these remedies, waste producers, provided their use has not been too long continued. It is a well recognized fact that there is an excessive accumulation of carbonic acid in the presence of inflammatory changes of tissue. In the presence of carbonic acid nascent oxygen is formed from chlorate of potash, which may show how the inflammation is relieved and oxygen furnished the fœtus. It is claimed on good authority that the chlorate of potash does not part with any great amount of oxygen at the body temperature, yet there remains the fact that by increasing the alkalinity of the blood its oxydizing function is augmented. Whatever its *modus operandi,* whether as a tonic or by its decomposition in the blood, thus directly furnishing an increased quantity of oxygen to the fœtus through the placental tufts, or whether it puts the blood in such a state that it is able to carry an increased supply of oxygen, the clinical fact stands that it has a direct beneficial effect in properly selected cases, that is, where there is fatty degeneration of the placenta.

Shoemaker, in his new edition, recommends chlorate of potassium in plac ntal inadequacy where there is deficient oxygenation of the blood. He gives it in 15 grain doses three times a day, thus preventing disease of the placenta, and enabling a woman to go on to term who had previously miscarried a number of times.

OUGHT INFANTS TO BE WASHED IMMEDIATELY AFTER BIRTH?

In a paper read before the Section on Diseases of Children at the Detroit meeting of the American Medical Association, Dr. F. S. Parsons, of Boston, says:

All wild animals dress their young directly after birth. The human mother, however, cannot perform such duties in the manner of the lower animals, whose offspring, moreover, are covered with hair, necessitating simply the drying of a wet surface; but the child, with practically no hair on the body, is ushered from an aqueous solution at a temperature of about 100° F., to an aërial temperature of from 20° to 30° lower. Apparently, to guard against this sudden cold, Nature has placed a sebaceous covering, which, if allowed to remain, would protect the child from the chilling influences of the reduced temperature. Dr. Parsons, however, does not so much object to the washing of the child as to the manner in which it is generally done, and which so often leads to catarrhal troubles, varying from simple snuffles to broncho-pneumonia. He recommends a little skirt with sleeves and hood, made of some soft unirritating material—for example, Canton flannel—in which the infant should be placed, after being quickly rubbed with pure hog's lard. Here it should remain for four or five days, when it would become accustomed to the lowered temperature, and could with much more safety be washed; but as this would not satisfy the average mother, he would advise covering the head and body with lard, then quickly placing the child in a tub of water at about 103° F. there cleaning and washing the body with a soft linen cloth. He has never seen a child so treated suffer from catarrhal troubles in any way.—*Medical News.*

RETAINED PLACENTA AFTER ABORTION.

J. A. Winter (*American Gynecological Journal*) gives the history of a case in which an abortion occurred and metrorrhagia supervened for the following six

months when decided uterine hæmorrhage appeared. Upon the supposition that some portion of the product of the last conception remained in the uterine cavity, the writer (who had not treated the patient at the time of the abortion) ordered fluid extract of ergot, in dram doses, at intervals of two hours, until three doses were given. The following morning, upon visiting the patient for the first time, the writer was shown a specimen of placenta and organized blood-clot, which had been expelled from the uterus during the night. The bleeding immediately ceased with the removal of its cause. Had the ergot failed to dislodge the mass the placenta forceps or curette would have been speedily used. During the discussion of the paper by the members of the Detroit Gynæcological Society, the use of ergot for such cases was adversely criticised, for the reason that the drug is apt to cause contraction of the lower as well as of the upper portion of the uterus. In cases where the os is tightly closed, opium is advocated to relax the cervix, and the employment of ergot is to be restricted to those cases in which the os is patulous. Concerning the treatment of abortion in general, the sentiment of the society was unfavorable to the so-called expectant plan. As soon as it becomes evident that an abortion is inevitable, the only safe plan to pursue is that of emptying the uterus. In reference to methods, the finger is to be used when practicable, the placenta forceps or curette at other times. There was some difference of opinion as to the best method of dilating the constricted os uteri, either for the purpose of expelling the ovum or for the control of hæmorrhage. Braun's colpeurynter was relied upon by some members, while a tampon of iodoform gauze packed into the cervical canal (one half to a yard long by one inch wide) was preferred by others. The thorough disinfection of the vagina, before and after the removal of the uterine contents, is obviously necessary.—*Arch. Gyn., Obst. and Ped.*

GYNECOLOGY.

CANNABIS INDICA IN THE PAINFUL DISEASES OF WOMEN.

Dr. J. B. Mattison, of Brooklyn, praises cannabis highly as an anodyne and hypnotic. It is not a poison, there is no fatal case on record. It must be given in full doses. Small doses are stimulating and exciting, large ones sedative. It is equally useful in dysmenorrhœa, especially of the spasmodic variety, and in painful chronic metritis. In many cases of uterine cancer it allays or prevents pain. It acts well in megrim, in the neuralgias, and headaches so common in anæmic women. It is a safe and excellent hypnotic in insomnia. The tincture must be given in doses of twenty to sixty minims, and of the solid extract, one-half to two grains. Farlow recommends the following suppository in dysmenorrhœa, to be introduced every night, beginning five days before the time of the period:

℞ Ext. cannabis indica.....
Ext. belladon.....āā..gr. j.
Ol. theobrom.....5 j ss.

—*Chicago Medical Times.*

LATENT GONORRHŒA IN WOMEN.

In these days we hear and read much of the woeful effects of latent gonorrhœa in woman contracted from the husband who supposed he was cured of the result of his folly, some time— a year perhaps, before his marriage. We believe that medical men ought to be very guarded in giving permission to marry to young men who have, within a short period, contracted a gonorrhœa, or who suffer from a gleety discharge. Want of caution in this matter is probably the reason why an unfortunately large number of young women, married in the best of health, fall into chronic ill health shortly after marriage, or become, in two or three months, victims to a fatal metritis or perimetritis after abortion.

In cases of this chronic gonorrhœa, the leucorrhœa is of itself of little diagnostic importance, as it may vary with wide limits, both as regards quantity and transparency, but it is usually yellowish-colored, as if mixed with pus, and non-transparent as it flows from the cervix uteri. The cervix is usually surrounded with an intensely red erosion, of some lines in width. The uterus is usually tender, and the regions of its mucous membrane adjacent to the mouths of the Fallopian tubes are specially tender. Inflammation of the urethra at an early stage of the disease is of great value, but it soon passes away. Much more value must be attached

to the condition of the vulvo-valginal glands, and the glands of Bartholin. The vulvo-vaginal glands are enlarged, and the vulva is sensitive. The existence of inflammatory catarrh of the glands of Bartholin is an important sign. On separating the labia minors from the remains of the hymen between the first and the under lateral caruncula myrtiformis in a woman who in former years has suffered from gonorrhœa, it is the rule to see an intensely red point, covered over with glairy mucus, from which as a centre a red streak, constantly becoming fainter, stretches upward and outward, and gradually becoming pale, passes over into the color of the surrounding mucous membrane.—*Mass. Med. Jr.*

ELECTRICTY IN PELVIC TROUBLES.

On the use of electricity for pelvic troubles, Dr. Price says: "It is utterly incomprehensible how any sane man can advocate the use of electricity; it seems that it is only in such hidden regions as the pelvic that the electricians claim any resulting good from their treatment, Why not apply this all-powerful, this infallible and omnipotent curative effect of electricity to the resolution of abscesses found in the neck of strumous children? Certainly wealthy mothers would pay well, even handsome fees, to save their children from carrying through life loathsome scars, not to mention the satisfaction of the operator upon curing his patient without the deformity resulting from the formation of a cicatrix."—*National Med. Review.*"

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, OCTOBER 2, 1892, TO OCTOBER 8, 1892.

Major Robert H. White, Surgeon, U. S. Army, is relieved from duty at Fort Myer, Virginia, to take effect on the expiration of the leave of absence granted him, and will then proceed to report in person to the commanding officer, Jefferson Barracks, Mo., for duty.

Major Daniel G Caldwell, Surgeon, U. S. Army, is relieved from duty at Jefferson Barracks, Mo., and will report in person to the commanding officer, Madison Barracks, N.Y., for duty at that place

Captain William C. Gorgas, Assistant Surgeon U. S. Army, is relieved from duty at Fort Barrancas, Florida, and will report in person to the commanding officer, Fort Reno, Oklahoma Ty., for duty at that post, relieving Captain John L. Phillips, Assistant Surgeon.

Captain Phillips on being relieved by Captain Gorgas, will report in person to the commanding officer, Fort Myer, Virginia, for duty.

Captain Henry D. Turrill, Assistant Surgeon, U. S. Army, is relieved from duty at Madison Barracks, N. Y., to take effect on the expiration of his present leave of absence, and will report in person to the Commanding Officer, Fort Riley, Kansas, for duty at that post, relieving Major John R Hoff, Surgeon U. S Army.

Major Hoff on being relieved by Captain Turrill, will report in person to the Commanding Officer, Fort Columbus, New York, relieving Major Johnson V. D. Middleton, Surgeon, U. S. Army.

Major Middleton, on being relieved by Major Hoff, will report in person to the commanding officer of the Presidio of San Francisco, California for duty at that post.

The leave of absence granted Major Alfred A. Woodhull, Surgeon U. S. Army, is extended ten days.

Captain Junius S. Powell, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Randall, South Dakota, to take effect upon the final abandonment of that post, and will then repair to Fort Monroe, Virginia and report in person to the commnading officer of that post for duty.

Major Robert M. O. Reilly, Surgeon U. S. Army will be relieved from duty at Fort Logan, Colorado, and will report for duty as Attending Surgeon in this city, on December 15. 1892.

Captain Alonzo R. Chapin, Assistat Surgeon, U. S. Army, is relieved from duty at Fort Yates, North Dakota, and will report in person to the commanding officer, Fort Hancock, Texas, for duty at that station.

Captain Eugene L. Swift, Assistant Surgeon, U S. Army, is relieved from duty at Fort Grant, Arizona, Terry., and will report in person to the commanding officer, Fort Yates, North Dak., for duty at that staton.

Lieutenant Colonel Frances L. Town, Deputy Surgeon General, U S. Army, is relieved from duty at the Presidio of San Francisco, Cal and will report in person to the commanding officer, Fort Porter, N. Y., for duty at that station.

Major Egon A. Kœrper, Surgeon U. S. Army, is relieved from duty at Fort Walla Walla, Washington, and will report in person to the commanding officer, Willets Point, N. Y. for duty at that staton, relieving Major Clarence Ewen, Surgeon.

Major Ewen on being relieved by Major Kœrper will report in person to the commanding officer, Fort Walla Walla, Washington, for duty at that station.

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co

Sulfonal-Bayer

induces sleep, free from narcosis, and sequelæ. It acts purely as a hypnotic and claims no analgic powers. Sulfonal is also of the highest value in the neuroses and is largely employed by neurologists. It is a safe remedy and its continuous use does not give rise to a drug habit. Sulfonal must be given according to directions. (*Supplied in ounces.*)

Salophen

is a new salicylo-phenolic derivative said to be so combined, chemically, as to constitute a safer and more effective remedy than either of its components, or any analagous preparation. The reports refer in the highest terms to its value in rheumatism and allied affections. Competent observers recommend it for extended trial. (*Supplied in ounces.*)

Europhen

is a complete substitute for iodoform and is a cicatrisant of special value in specific lesions, catarrhal and ulcerative diseases and all surgical conditions formerly treated by the latter preparation. It has five times the covering power of iodoform and forms an impervious coating over denuded tissues. Europhen has a faint, agreeable odor resembling that of saffron. (*Supplied in ounces.*)

Phenacetine-Bayer

continues to justify the high praise of physicians, and it may properly be considered as the best of the modern antipyretics and anodynes. In *la grippe*, rheumatism, migraine, neuralgia, etc., it is a prompt, safe and effective remedy. Phenacetine, unlike the secret mixtures announced as analgesics and antipyretics, is a true organic derivative. (*Supplied in ounces.*)

Aristol

is now widely used as an agreeable and effective dressing in all of the operations of major and minor surgery and in dentistry. It is invaluable in ulcerations of all kinds, and in burns, blisters and bed-sores. It adheres closely to mucous membranes and wound surfaces. (Aristol and "Europhen-Aristol," a combination of both remedies are supplied in ounces.)

Full Descriptive Pamphlets sent on application.

W H Schieffelin & Co New York

FRELIGH'S TABLETS,

(Cough and Constituent).

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{600}$ gr.), Codeia ($\frac{1}{60}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

68 Maiden Lane, **New York City**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

THE USES AND ABUSES OF COCAINE WITH REFERENCE TO MUCOUS MEMBRANES ESPECIALLY.

By ARTHUR G. HOBBS, M. D.,
EX-PRESIDENT OF THE AMERICAN RHINOLOGICAL ASSOCIATION, MEMBER OF THE AMERICAN MEDICAL ASSOCIATION, OF THE GEORGIA STATE MEDICAL ASSOCIATION, THE ATLANTA SOCIETY OF MEDICINE, ETC., ETC., ATLANTA, GA.

Since I received my first twenty grains of the hydrochlorate of cocaine (a part of the first two drachm package that arrived in New York), I have used many ounces; perhaps, altogether, by myself and assistants, as many pounds as my original package contained grains.

It will not be amiss for me to say in the beginning that I now have very different opinions of its uses, from those I entertained during the first year of its advent. However, one of my original opinions of its applicability has only become more and more confirmed with my increased use of it; and that is that its utility is principally confined to its local application to mucous membranes.

The softer the mucous tissue to which it is applied, the sooner is its effect reached and the less the quantity necessary; and, as a consequence, the quicker and more decided is the toxic effect when its application is persisted in to this extent.

The general symptoms, however, are, everything else being equal, much oftener present in proportion to the area of membrane surface involved, than in proportion to the strength of the solution applied. Hence, sprays of a weak solution are liable to produce toxic symptoms, when much stronger solutions can be applied with a saturated cotton probe or wad, to a limited area, almost with impunity.

The constitutional effects of cocaine are manifested by a feeling of faintness—it may be even to the loss of consciousness—a trembling of the limbs, a pallor of the face, etc., any or all of which may appear in one minute or in fifteen minutes after the application to a large surface. Again, these symptoms may be produced by a small quantity of a one per cent. solution in one individual and not in another; even if in the latter both the strength and quantity be ten times multiplied. I have never yet reached a conclusion as to the average amount of cocaine that is necessary to produce the constitutional symptoms; neither do I ever know, the first time I use it, how to estimate the individual's susceptibilities.

Every individual seems to be a law unto himself as to the quantity necessary in his own case to accomplish complete local anæsthesia; and even in the same person the amount will vary at different times, with no apparent cause. Under similar circumstances I find it impossible to reach a complete local anæsthesia in some, short of the toxic symptoms; when in others, one-tenth of the amount will render the application of a galvano-cautery absolutely painless.

To obviate the unpleasantness and delay caused by the constitutional symptoms, it is my custom to administer a stimulant of brandy or whisky at their first indications, and make the operation quickly and, always under such circumstances, painlessly. When it is found by trial that one bears the drug badly, it would be well to always give a stimulant before the second application is made.

I am sure that the last thousand galvano-

cautery operations I have made would represent a much greater per cent. that were absolutely painless, than the nearly three thousand cauteries that preceded. Perhaps this has been due to my greater familiarity with technique of cocaine applications in the more recent cases.

In some, its effects in the superior pharynx are peculiarly distressing, more especially at the first application, but less and less so afterwards. However, it is well to remember this and avoid it, when making local applications above, by not allowing the solution to gravitate from the cotton plug.

The time necessary for cocaining a mucous membrane is perhaps as indefinite as the strength of the solution; both due to that unknown quantity—the individual. Approximately, however, four to ten minutes and a four to ten per cent. solution for a small surface may be regarded as an average. If the intention is to produce the effect over a small surface only, as in galvano-cautery operations, a concentrated solution—ten to twenty per cent.—should be used, and the result expected in four to eight minutes. If, however, a general turgescence of any membrane should suggest the use of cocaine, then a spray of a very weak solution—a one or two per cent.—should be expected to accomplish the desired result in one or two minutes. In either case, the general effects may appear without any warning and mar the anticipated good results or, at least, render an otherwise easy operation, tedious and unpleasant.

It has been my custom, from the beginning, to make my solutions at the moment I use them and to vary their strength according to the case, and as I use no weights or measures, I never know, only approximately, the strength. The range is so great that I hesitate in stating it, as I have not space to give my reasons for sometimes using a one grain to the minim solution, and again, only a one grain to five hundred minims. As a general rule, however, the strength should be in inverse proportion to the surface to which it is applied. Since my many disappointments with ready-made solutions of cocaine, during the first few months of its advent, I have never risked any solution that had not been recently dissolved.

In case it should be necessary to dissolve a large amount, it would be well to add boric acid for its preservation, in a proportion of about one grain of the latter to ten grains of the former.

For safety, it is best to supply the drug instead of giving the patient a prescription to have filled and bring with him for an appointed operation. The operation will thus be less magnified in the patient's mind and he will be less liable to familiarize himself with the proportions and uses of the drug, should the temptation to use it himself arise afterwards. For these reasons, I do not, in any instance, give a patient a prescription containing cocaine as a leading ingredient.

As an ingredient in sprays, I find it abused more, perhaps, in hay fever prescriptions, than anywhere else. This is true also where it is prescribed in the form of powders for this disease.

The turgescent condition of all the mucous membranes of the upper respiratory tract, especially in the nasal turbinates, that is always present in hay fever patients, is so quickly palliated and rendered bearable, that the temptation is great to prescribe cocaine in some form for the patient's own use; but it is a dangerous experiment and one to be ventured upon only in exceptional cases.

During the past few years I have seen many journal articles that claimed for it a decided aphrodisiac effect, while my observations have been universally to the contrary. It will not be departing too far from the subject if I mention the effects of cocaine (through the mucous membranes) upon two cases of priapism, notwithstanding the fact that the results in these cases were reached through the general systemic impressions of the drug. The two young men, who were the victims of this rather unusual disorder, came under my observation by accident, and at intervals of about three years, each came to my office in a carriage for a coincident nasal and pharyngeal inflammation. Cocaine dissolved in vaseline, together with a small quantity of campho-mentholine, was sprayed into the nasal and pharyngeal cavities to the great relief of all the unpleasant symptoms in these regions.

But this was not all. In the first case, to my surprise and to the patient's great joy, the other and more painful malady disappeared within ten minutes. In the second case the symptoms were almost exactly like the first, and the patient's de-

light was greater than my surprise, as I was this time anticipating a similar result from the same treatment. The relief of the priapism, in both cases, remained permanent.

In both instances, the usual treatment for such cases had been resorted to apparently without result for 24 and 36 hours respectively, only to be completely relieved by a cocaine spray used upon a distant mucous membrane for a coincident malady. It would seem that in these cases cocaine acted as an anaphrodisiac, and it should not be surprising when we remember that its primary effect is to reduce a turgescence of the turbinates, and that these tissues are analogous in many respects to the erectile tissues that are involved in priapism.

I desire here to emphasize most decidedly one contra-indication in the use of cocaine as a collyrum, and that is that *it should never be used when an abrasion of the cornea exists*; nothing in the form of a collyrium is more deceptive, as it is also most grateful to a denuded corneal surface.

The cornea is covered with the epithelial layer of the conjunctival mucous membrane only; here no middle layer proper exists whence it can derive its nutrition, hence it quickly looses its vitality when subjected to this local anæsthetic. So also the outer layer of the cornea, receiving its nutrition by imbibition only, seems to be even more susceptible to the destructive effects, of cocaine.

I have seen a number of cases, during the last few years, (especially since this drug has been introduced into general use) in which the cornea has been greatly damaged by its constant and frequent introduction, for no other purpose than the temporary relief of pain; but unfortunately the relief thus produced proves to be a delusion and the destruction produced upon the cornea is only masked for the time by the anæsthetic effects.

I have especially seen these bad results in the cases of physicians who had themselves persisted in its use for the comforting effect to their own eyes, both during the presence of foreign bodies on the cornea and after their removal.

Cocaine is contra-indicated also in any corneal inflammation and should not be prescribed beyond the acute stage of any form of conjunctivitis.

I have had but little experience in its use beyond its local application to mucous membrane surfaces, because I have never believed that its range of utility extended any further, except, perhaps, in a very few instances, hence I know very little of its general usefulness hypodermically, as it has usually seemed to be quite as painful to introduce it in this manner, as the pain of the minor operation would be, especially when we consider the limited quantity that can be borne when it is introduced so directly into the circulation.

I have sometimes however injected the solution into the tonsilar mass to hasten anæsthesia, but the toxic effects follow so quickly after its introduction into the circulation in this manner, that I always hesitate to resort to this means in an untried subject.

Yet in some operations on the eye as in tenotomies, iridectomies, cataract operations, etc., I frequently use the syringe for introducing a weak solution—1 to 2 per cent.—sub-conjunctivally, on subjects that do not succumb to a 4 to 6 per cent. solution applied superficially for fifteen to twenty minutes at short intervals.

In preparing for a tonsil amputation, I use a cotton probe saturated in a five to a fifteen per cent. solution, and apply it to the whole surface of the mass once; then I send the patient to a waiting room and perhaps in the meantime—about eight or ten minutes—see another patient, then make a second thorough application and wait three to five minutes before I use my knife and hook tonsilotome.

Occasionally, in an extremely sensitive patient who has not by this time exhibited any of the general effects, a five per cent. solution may be introduced into the tonsilar mass with a long hypordermic needle before proceeding to amputate.

In nearly five thousand tonsil amputations (four-fifths of which were done under cocaine) I never had a dangerous hæmorrhage and not more than a dozen cases that even proved to be troublesome from this cause.

Undoubtedly, cocaine exerts a decided hæmostatic effect upon hypertrophic tissue, especially when it has thoroughly saturated the mass before an incision is made. Yet, after the solution of continuity, its blood-staying qualities are not equal to many other hæmostatics, and it cannot be relied upon for this purpose.

During the first years of its use, this drug was vaunted by many writers in the medical journals as a great panacea—as the sovereign remedy for ear-ache but naturally, disappointment followed quickly in the practice of these theorists, who seemed not to remember that the outer layer of the membrana tympani was not a mucous layer, else they failed to remember the fact that an aqueous solution of cocaine could be only sparingly absorbed through a cutaneous epithelium.

After the rupture or incision of the drum membrane in an acute catarrhal inflammation of the middle ear, when it becomes possible for the solution to reach the membrane involved, the call for relief from pain has already ceased. When it is practical to produce a few drops of a strong solution into the middle ear cavity through the eustachian tube, the pain is usually relieved at once; but as it is not always possible to do this on account of the swollen mouth of the tube and as another question arises here beyond the scope of this paper, as to the advisability of the trial in any case, cocaine cannot be regarded as so great a panacea in ear-ache as it was first claimed to be by many who wrote only upon faulty theoretical grounds.

I have occasionally heard of cocaine habitues, all of whom were physicians, but I have had no personal experience with these unfortunates. Such cases will be found to be linked with whisky habits in the great majority of instances.

I think, however, that we should always remember the danger of such a consequence when making a prescription containing cocaine, and be guarded when even its suggestion arises.

Like all other drugs that are potent for good, cocaine is also potent for evil. Like fire, it is a good servant but a bad master.

PYLORIC PAIN IN DYSPEPSIA.

Coutaret, according to the *Revue de Thérapeutique Médico-Chirurgical,* advises the following treatment in the pain of dyspepsia:

℞ Saturated chloroform-water.....ʒ iv.
Simple syrup of colombo.....ʒ iss.
Powdered extract of cannabis indica..gr. iiss. M.

Sig.—A dessertspoonful of this may be taken every half hour until the pain is relieved, particularly at the time that the chyme is passing from the stomach into the intestine.

THE INFLUENCE OF TOBACCO ON VISION.*

BY FRANCIS DOWLING, M. D.,
CINCINNATI.

As far back as 1833, a Scotch physician, Dr. McKenzie, of Glasgow, first called attention to the influence which tobacco exerts in the causation of certain kinds of blindness, in these words: I have already had occasion repeatedly to hint my suspicion that one of the narcotic acids, which custom has foolishly introduced into common use, namely, tobacco, is a frequent cause of amaurosis.

During the year 1884, while in Paris, in the eye clinic of Dr. Golezowsky I collected some information bearing on this subject, and more recently I have made a series of examinations of the employees of the principal tobacco factories of Cincinnati, with the same object in view.

I here give a synopsis of my findings in one hundred and fifty of these selected cases.

There were altogether about 3,000 employees in these factories which I visited, about the half of these were females and the other half males. I found that ninety per cent. of all the male employees, used tobacco in some form or other. About twenty per cent. chewed tobacco in addition to smoking liberally of a pipe or cigars; most of them did their smoking in the morning and evening before and after working hours.

One woman aged forty, presented a well marked case of tobacco amblyopia—she confounded the red and green colors of the test with black, and white with dark gray. She also presented a notable diminution of her visual acuteness and said her eyesight had been failing for the past two years. She had been working in tobacco for five or six years but has never used the article in any shape.

Comparatively few of the men examined drank to any great extent, and those who did, drank mostly beer.

A very large number of the men appeared to have a flabby condition of the muscles, and to suffer more or less from anemia. This was particularly noticeable

*A paper read before the Mississippi Valley Medical Association in its 18th Annual Meeting at Cincinnati, October 12 to 14, 1892.

among the female employees who were largely made up of young girls.

The ventilation of the work rooms was, as a general thing, as good as could be expected in establishments of this kind.

The principal colors confounded, by those who were examined were red confounded with pink, dark brown or black, the latter usually in the more pronounced cases; green was confounded with light blue, yellow or black. White was as a general thing confounded with grey of different degrees of intensity, according to the degree of tobacco infection. All of these cases were only affected for the central colors in the test,—the colors in the periphery could be distinguished without much difficulty.

The men examined ranged in age from thirty to sixty years, and were among the heaviest consumers of tobacco in the factories, so that they were among the best subjects that could be had for the object in view, viz: ascertaining the effects of tobacco on the system.

In my first series of examinations, some of the females were included in the list, but with the exception of the case already named, none gave evidence of tobacco poisoning, as manifested by troubles of vision.

Out of over 150 men examined there were forty-five, who showed more or less evidence of tobacco amblyopia, the majority of these, however, were of a light degree, but thirty, however, among the number were pretty well marked cases as they distinctly mistook the red color of the test for brown or black, and the green color for light blue or orange, and in some instances black. They were also unable to make out the white spot in the center of the visual field.

The majority of those who were examined, that is of the whole 150, showed evidence of a contracted condition of both pupils. This was present in a good many who showed no other evidence of tobacco poisoning, but it was marked and persistent in those who showed other well marked evidence of tobacco infection.

Thirty out of the forty-five complained of a gradual failure of vision. Three-fourths of all the men examined were over thirty-five years of age, and the oldest man examined was aged sixty-one years.

Some of the men examined smoked as high as twenty cigars a day. In several instances, the proprietors of the establishments where the examinations were made pronounced themselves skeptical in regard to tobacco having any deleterious influence on the eyes. They were very much surprised when they found that they confounded the colors on the test chart, and were finally convinced that tobacco could have a bad influence on the eye-sight.

When I commenced my examinations, I was under the impression that the constant inhalation of the dust and odor of the tobacco in the workshops would tend in itself to bring about symptoms of tobacco amblyopia. I am inclined to think this hardly takes place, for in my examination, I found that those who did not smoke or chew were uniformly free from troubles of vision of a toxic nature and the females were almost universally free from the trouble, that is, as far as I examined them.

As a result of all my investigations in this department, the following would be a fair resumé of the principal symptoms, which characterize chronic tobacco poisoning, affecting both the general system and the organs of vision:

General Symptoms:—The subjects are light eaters, and the appetite is easily satisfied. A large number have a decided antipathy to meat, constipation is usual, the sleep is usually disturbed, often by disagreeable dreams. They usually have to go to bed late, as they claim in order to be able to fall asleep. They often wake up in a few hours, and are unable to go to sleep for some time. They usually complain of more or less palpitation of the heart and the pulse generally ranges at about 90 or over. On taking any great amount of exercise the muscles feel unusually tired, and the hand often has a characteristic tremble on holding a book or pen. A case in which this latter symptom was particularly well marked came under my treatment recently, in a man who was a heavy smoker, and had pronounced symptoms of tobacco amblyopia in adddition.

Eye Symptoms:—The subjects who usually suffer with tobacco blindness are almost always males between the ages of 30 and 60 years. Exceptions to this occasionally occur, and in my own series of examinations I found one young man aged 19, who presented a well marked case of this trouble. The young man was a most inveterate

smoker and chewer of tobacco. Noyes also states that he treated a boy of 15, who presented a classical case of this disease. The boy was an inveterate cigarette smoker.

There is almost always a gradual but progressive failure of visual acuteness, in in both eyes. This was noticed more or less in a large number of all the cases which I examined.

Luminous objects dazzle the eye-sight, and a bright light is worse for reading by than a subdued one. The patients see better in the evening than in the middle of the day and in this connection Forster cites the case of an old smoker, who in playing nine pins could not distinguish between the upright pins and those that were down, during the bright light of day, but had no difficulty in that direction as evening came on. In addition to this patients often complain of a glimmering mist which covers all objects, especially in a bright light.

These subjects almost always confound colors, for central vision; first in the order comes red; this is generally taken for dark brown, pink or black; next in order comes green. This color is taken for light blue or black. Then in order comes white, which is taken for dark gray or black. Pink to these subjects often looks like blue. It must be remembered that it is only for the central visual field that these colors are confounded; the periphery is usually seen all right.

Myosis:—Persistent contraction of both pupils is generally present, and this was the most frequent of all the symptoms noticed in the cases examined, and we could almost always tell by looking at the pupils in advance of the rest of the examination, that the subject would fail to make out the colors of the test. This symptom was present, in many cases where the men were heavy chewers of tobacco, even when there was very little other evidence of infection.

It would be well here to mention that in some cases, this contraction is so pronounced that it is impossible to illuminate the eye chamber sufficiently to make an examination of its fundus by means of the opthalmoscope, and in consequence this condition may be mistaken for other disease, for a case on this point I am indebted to my friend and former teacher, Dr. Galezowski, of Paris. The case was treated by the Doctor in 1889, and he writes me the particulars under date of last August as follows: A man in the island of Martinique, suffered a diminution of vision to such an extent that he was no longer able to go about without assistance. He consulted a doctor on the island who examined him and said that he had a cataract and advised an operation. The patient's wife took him to Paris and asked Galezowski to perform the operation. The Doctor, before operating, made a careful examination and was surprised to find no trace of cataract.

The patient had instead a marked case of tobacco amblyopia from smoking from 20 to 30 cigars a day. He was placed under appropriate treatment. The use of tobacco in any form was strictly forbidden him as well as alcohol. In about three and a half months the man had entirely recovered the use of his sight, without operation.

It will be well to mention that all the symptoms spoken of are more marked in the case of chewers of tobacco than in smokers. This we can probably explain by the fact, that in the case of chewing, more nicotine is absorbed, than in the case of smoking—for in the latter case a great part of this poisonous agent is volatalized by the heat and escapes with the smoke—while in the former, most of it is directly absorbed into the circulation through the blood vessels of the mouth and tongue.

Lastly, the opthalmoscopic examination of the eyes of those affected with tobacco amblyopia reveals the papilla of the optic nerve to be more than usually red in the early part of the affection, later it appears anemic, especially on the temporal half, and finally atrophy of the disc takes place. It is quite probable that these changes in the papilla are caused by direct action of the nicotine, which enters the circulation, and causes contraction of the smooth muscular fibers, and then diminishing the caliber of the minute blood vessels of the part, irritation of the nerve tissue of this essentially sensitive body takes place at the same time, by the same agent, and this explains the congested condition of the part seen in the early history of the disease. The pressure, etc., caused by the congestion, finally causes a gradual atrophy of the disc and eventually more or less of the contiguous retina, according to the duration of the disease, and the amount of tobacco infection.

Communications.

MYXOMA OF THE NOSE, AND FIBRO-MYXOMA OF THE NASO-PHARYNX.*

BY S. G. DABNEY, M. D.

CLINICAL LECTURER ON DISEASES OF EYE, EAR, NOSE AND THROAT IN THE HOSPITAL COLLEGE OF MEDICINE, LOUISVILLE, KY.

Myxomata are much the most frequent of nasal tumors. Zuckerkandl is said to have found one polyp in every eight or nine autopsies, but from his own description it is evident that he included many cases of hypertrophy and of other growths, in his list of polyps. Bosworth in private practice has found one polyp to every eleven cases of ordinary catarrhal inflammation of the nose. In my own experience they have certainly not formed so large a proportion, probably because of the wide prevalence of catarrhal inflammation in this region. Myxomata may occur at any age, but are much most frequent after sixteen. As regards their cause, nothing definite is known; but it is a significant fact that the favorite site for their origin is in the mucous membrane covering and beneath the middle turbinated bone.

McBride and Bosworth both find the exciting cause of nasal myxomata in a "water soaked" condition of the mucous membrane—a condition especially prone to occur in the area just named, partly from the structure of the mucous membrane here, and partly from the narrow space between the middle turbinated and the unciform process, which may easily be closed by a little swelling and thus the bony ridges brought into contact. It is a little strange that recognizing this state of the mucous membrane as the underlying cause, Bosworth nevertheless advises no treatment further than the removal of the growth.

Some years ago Woakes advanced the view that a necrosing ethmoiditis was the exciting cause of nasal polyps. This opinion is not generally held by other surgeons, and has been subjected to much criticism. Lennox Browne, Walsham and Hill at a recent meeting of the British Medical Association, asserted that to find ethmoidal disease at all in this connection, is very unusual, while McKenzie, Bosworth and others, insist that Woaks has confounded cause and effect, and that ethmoidal necrosis when it does exist is the consequence of the nasal polyp, not the cause. This opinion is substantiated by the fact that bone disease is not common where there is but a single polyp, but is to be found where there are a great many, and especially after they have existed for some time.

The most exact investigations into the situation of nasal myxomata have been made by Zuckerkandl. In thirty-three autopsies he found the polyp to originate from the lips of the hiatus semilunaris fifteen times, from the edge of the middle turbinated four times, from the subjacent bony eminences six times, and from the septum three times. The growths on the septum were all sessile and probably were hypertrophies, rather than true polyps, since by other observers the septum has only very rarely been found to be their site, McKenzie stating that the cases reported by Bryant, Leriche, Wagner and Hartman (each one case) were the only authentic instances within his knowledge. The origin of at least two-thirds of nasal polyps at the edge of or beneath the middle turbinated bone has important practical applications in their treatment, since, as an inspection of this region on the dried bone will show, it must often be impossible to reach the base of the polyps without removing a piece of the middle turbinated.

The diagnosis of myxomata is usually easy; their color, consistency, mobility, location and painlessness distinguish them from other growths. The greatest liability to error in this respect lies in overlooking small polyps which are deep situated beneath the middle turbinated. In every suspicious case this situation should be thoroughly examined, a pledget of cotton soaked in a four to ten per cent. solution of cocaine being first packed in under the bone to produce anæsthesia, and to contract erectile tissue.

Where there are several polyps, the mucous membrane covering the middle turbinated is sometimes found to be in a state of myxomatous degeneration, with

*Read before Medico-Chirurgical Society of Louisville, Ky.

irregular polypoid hypertrophies growing from its side and each end. In a small proportion of cases the cells of the ethmoid are continued into the middle turbinated and its anterior end bulges toward the septum; on removing the shell of bone covering this prominence, the cavity will be found occupied by one or more polyps having the appearance of a cyst. I have seen two such cases in my own practice.

The symptoms produced by nasal polyps vary in different cases. Sneezing which Bosworth has found almost always present and very persistent, has, in my patients, been often absent.

A sense of pressure about the bridge of the nose is usually complained of, and when the polyp is large there is obstruction to nasal respiration on that side. Sometimes the only symptoms mentioned by the patient are reflex ones, referring to other organs. Recently a lady consulted me on account of overflow of tears and "weakness" of one eye. She made no mention of nasal disturbance and was greatly surprised when I removed several polyps from the corresponding side of the nose. The epiphora caused by nasal polyps is usually attributed to pressure on the nasal duct, but bearing in mind the soft consistence of the tumor and the bony walls of the canal, it seems to me much more probable that it is due to reflex lachrymation.

Bosworth has found an astonishingly large proportion of polyp cases in asthmatic patients; thus, in thirty-four cases of hay fever asthma there were nine cases of polyps, while of forty-six cases of perennial asthma, eighteen were the subjects of nasal polyps. Not less remarkable are the results of treatment in Dr. Bosworth's hands. Of five cases of hay fever asthma, three were cured and two improved by removing the polyp and straightening the septum, while of eighteen cases of perennial asthma, fifteen were cured and three improved by simply snaring away the polyp. The experience of other specialists hardly agrees with that of Bosworth, either in the large proportion of polyp cases among sufferers from asthma, or in the very favorable results to be obtained by removing the polyp when present. I know of no other statistics on the subject, but the general opinion of writers is that nasal obstruction is far from being always present in cases of asthma, and that when it exists, its removal more often alleviates than cures the disease. McBride, however, relates a case in which the removal of a polyp too small to cause obstruction was followed by immediate and great relief to asthma.

This reflex influence of small growths is now well established and shows the fallacy of the opinion expressed by McKenzie, that polyps requiring treatment are generally between a currant and a grape in size. Various other symptoms have been attributed to nasal polyps; serious organic disease of the eyes, epilepsy and megrim, but no such cases have come into my own experience. The sense of smell and consequently of taste is often impaired, and where mouth breathing is necessitated for a prolonged time, its injurious effects on the throat and lower air passages are likely to ensue. Tinnitus aurium and deafness are often produced by nasal myxomata, but are much more commonly associated with post-nasal polyps, to be presently described.

The treatment of nasal myxoma consists in the removal of the growth, and appropriate applications to prevent its recurrence. The method of operating advised by some, even of the most recent, textbooks on general surgery seems strangely out of place in this day of perfected examination, and surgical technique. Thus, a voluminous work which has recently appeared recommends that the patient should be in the recumbent position, and that the surgeon introducing forceps should grasp the growth and twist off with it a portion of the middle turbinated, and that a general anæsthetic should usually be given. Not a word is said as to the use of the nasal speculum and reflected light to illuminate the nares and accurately locate the polyp. But only by such means is a thorough diagnosis possible. The polyp being seen, a four per cent. (or stronger) solution of cocaine should be applied around and on it, either as a spray or as I prefer soaked in a pledget of absorbent cotton. Used in this way we are less likely to produce constitutional symptoms or to have the cocaine get into the nasopharynx with the unpleasant sensations which that causes. Local anæsthesia and contraction of the blood vessels having been thus induced, a snare should be introduced, the wire loop worked as well as possible around the pedicle of the

polyp and the growth removed. Operating in this way there is usually very little pain and very little hæmorrhage—often none. For anterior growths such as we are now describing, I prefer the reel snare of McKenzie and No. 5 piano wire; the different forms of snare, however, are numerous and most of them are good. So far the line of treatment is well-defined, but as to what further measures are necessary authorities do not always agree. At the last meeting of the American Laryngological Association, the radical treatment of nasal myxomata was the subject of considerable discussion. Sajou Roe, Jarvis, Rice and Mulhall agreeing that in many cases a portion of the middle turbinated must be removed in order to get thoroughly to the point of attachment of the nest of polyps beneath it. Sajou, operates with rongeur forceps and applies electro-cautery; Roe uses the saw of his own device; Jarvis and Mulhall use Jarvis' snare and small searching forceps. The operator, if possible, should have each of these instruments at hand, as each will sometimes be found the best. For removing the edge of the middle turbinated, I use generally the reel-snare. When the edge of the bone cannot be caught in this way the rongeur forceps are used with advantage. I have found this little instrument so useful in various nasal operations, that I wonder now how I did without it. Since severe reaction and, it is said, even fatal meningitis, has followed removing the shell of the middle turbinated careful antiseptic applications should precede and follow the operation. I use the solution of Seiler's antiseptic tablets and sometimes of bichloride of mercury. As an application to the base of the polyp, nothing is better than the electro-cautery, though chromic acid fused into a bead on the end of a probe can be used with equally good effect.

After removing the polyp Cohen recommends washing out the nose with distilled extract of hamamelis in alcohol. Sprays of alcohol, first diluted with three parts of water and gradually increased to pure strength, are also advised by McBride, Griffin and others.

There is another form of tumor largely myxomatous in character, which originates in the nose and hangs into the post-nasal space. It is described by most authors as myxo-fibroma of the naso-pharynx. Such growths in my experience are not usually associated with anterior nasal-myxoma. They are generally single though sometimes bilateral. I recently removed a large myxo-fibroma from each post-nasal passage of a little boy thirteen years old. He had no other nasal affection. The growths were attached, as they usually are, near the margin of the nose posteriorly. I removed them with the Jarvis snare introduced through the nose, and guided by the rhinoscopic mirror. These growths are harder than true myxoma and not so hard as fibroma; they are usually distinctly pedunculated and move about with the movements of the palate and with change in position of the head. Nasal obstruction is generally the first symptom observed; the voice is changed and pressure on the mouth of the eustachian tube often causes deafness and tinnitus aurium. Such growths are generally invisible by anterior examination, and the diagnosis should be made by the rhinoscopic mirror. When this cannot be used, the finger introduced behind the palate and directrd to the post-nasal cavities will give knowledge of the tumor and its consistence. But usually, even in children (not infants) a rhinoscopic view can be obtained. The attachment and consistence of the growth can be ascertained by passing a probe through the nose, directing its manipulation with the rhinoscopic mirror; if the probe is wrapped at the end with absorbent cotton and dipped in a four to a ten per cent. solution of cocaine, it prepares the parts at the same time for operation.

Such tumors should be removed by the snare,—I prefer to introduce Jarvis' snare through the nose; during introduction the wire should be drawn into a small loop and when the snare is in place, it should be pushed out to the required length. Of course cocaine should first be applied which can best be done by the probe introduced as just described.

In the case of one, a very nervous lady, I found much assistance from a dose of valerian given by her family physician just before she came to my office.

If, for any reason, the snare cannot be used, the electro-cautery may be applied either through the nose or post-nasally. Where the growth hangs down over the edge of the soft palate, it may be grasped

with forceps and pulled out, but this method is inferior to the snare.

There is not much tendency to recurrence, but as a matter of precaution it is well to touch the place of attachment of the polyp with chromic acid or the electro-cautery.

The following case of post-nasal polyp hanging into the pharynx and causing persistent vomiting, with great emaciation and exhaustion, presents some unique features: A negro man between twenty-five and thirty years old referred to me through the kindness of a general surgeon to consult whom he had come from a neighboring county. The patient was extremely emaciated and so weak that he could walk only with difficulty, and with the help of a stick. He breathed through his mouth and spoke as if his mouth was full. On looking into his mouth a tumor was seen lying on the tongue and looking exactly like a double tongue. At first sight it seemed to be attached low down in the pharynx, but more minute examination showed it to hang from the post nares and to be bent over the palate. The portion in the mouth was reddish brown in color, firm in consistence and free from sensibility on touch or pressure. It was very movable and evidently attached by a narrow base. The patient gave a history of nasal obstruction for about two years, and of nausea becoming more and more intense for the last six months, until for some eight weeks past he had been unable to retain anything on his stomach and his emaciation and weakness were the consequence. On the day before I saw him in the course of his vomiting he had thrown up into his mouth the tumor which now rested on his tongue. Being uncertain as to the vascularity of this tumor, I determined to remove it with the electro-cautery loop; the wire was introduced over the end of the growth in the mouth and pushed up as far as possible into the post nasal space; the mass so included was then burnt off without pain or hæmorrhage. The remaining base of the tumor was destroyed by the electro-cautery introduced through the nose. It was attached near the posterior margin of the right nasal chamber. The portion removed through the mouth was submitted to Dr. Louis Frank for microscopic examination and he reported as follows: "A tumor somewhat pear shaped, three and one-half inches long, and three-quarter inches in diameter in its thickest part, having at the ends a soft feeling, but in the central part feeling hard and nodular. On section the tumor is composed of numerous cystic (?) cavities filled with a cheesy material that is non-adherent and which easily rolls out. Microscopically the section shows large alveoli or cyst cavities filled with a substance partly cellular (round cells) and partly composed of a granular detritus, the remains of pre-existing cells. These cells stain very poorly. The cyst wall is lined with columnar epithelium, some goblet cells being present. The walls of the cyst are composed of a dense, hard fibrous tissue, containing few blood vessels. Section through portions of the tumor not containing the cyst, show only a fibrous structure.

"Diagnosis: Fibro-cystic polyp."

In the light of this report and knowing the tendency to cystic degeneration, characteristic of nasal myxoma and myxo-fibroma, it seems to me probable that this growth was a genuine myxo-fibroma which had undergone cystic degeneration.

THE PATHOLOGY OF OLD AGE.*

R. H. GRUBE, M. D.

The term old age is a very indefinite one for the reason that the systemic changes which cause the senile state take place at different ages in different people. The broken-down, decrepit day-laborer, whose life has been one of hard work and poor nourishment is more senile at fifty than a Gladstone at eighty. It is this senile condition then that will receive our consideration this evening.

As a basis for what I have to say I have taken the reports of the surgeons of the five largest National Military Homes, and my own observations during several years' service in the largest home. These five homes have an aggregate membership, in round numbers, of twenty thousand old soldiers, the average age of whom is about sixty-five. The total number of deaths at these homes occurring during the year ending June 30th, 1891, was 950. Select-

*Read before the Allegheny County Medical Society.

ing some of the principal causes of death they are as follows:

Heart lesions	151
Pulmonary Tuberculosis, including Fibroid Phthisis	122
Cerebral Hemorrhage	67
Senile Debility	62
Cancer	36
Bright's Disease	37
Pneumonia	37
Meningitis	20

As I will revert to these figures from time to time, I will not comment on them here.

I will follow the physiological plan in treating of the subject before us; but before taking up the individual systems I will call your attention to the senile state in general. The senile state is essentially one of general atrophy; the stature and weight decrease; mental and nervous activity lessen; and hair follicles atrophy as do the gladular and muscular tissues throughout the body. The only general tissue which does not atrophy is the connective tissue which, being nature's repairing cement predominates everywhere. This senile state is not pathological but physiological, for the person may have all of these evidences of senility and yet have good health.

Speaking in the language of the evolutionist we may say that the person who has resisted the enemies of life until he has reached old age, has demonstrated his fitness to continue to live until the natural period of human life, so we find in old age comparative immunity from infectious diseases. In my list there no case of smallpox or typhoid fever and none treated. However this rule is not without exceptions, Louis XV. of France died of smallpox at the age of sixty-five, and I have seen varioloid in a patient over eighty. In this connection may be noted the large toleration of morbid processes and the lack of sympathetic reflexes rendering these processes so obscure that they are often overlooked. I have many times had to bear the mortification of a post-mortem diagnosis because of this, and that too, after a most diligent search for the cause of the trouble. I call to mind several cases illustrating this point, some of which I will relate briefly. The first of these was that of a very old man, with a peritonitis caused by a perforated cæcum. He suffered no pain. I aspirated several times, removing two or three pints of most offensive pus each time, and the patient finally died of exhaustion. Another was a perforating ulcer of the duodenum—post-mortem diagnosis—where the contents of the stomach escaping caused adhesive peritonitis, burrowed a channel and "pointed" two inches below the umbilicus. A third case was one of cerebral hæmorrhage causing deep coma, and death in seven hours. The hæmorrhage was in the interior of the Pons Varolii and had completely destroyed the tract of connection between the brain and cord. We see the lessened sympathetic reflex, too, in the narrowed variation of the temperature even in inflammatory conditions. A temperature of 103° is unusual, and I scarcely remember to have seen it at 104°. Nor is the temperature lowered as might readily be supposed. A lowered rectal temperature in old age will most certainly indicate a lesion of some sort, usually visceral. These conditions render diagnosis in diseases of old age difficult, and, as I have already said, many times the real trouble is not discovered at all during life. Thus a patient in one of my wards complained of all sorts of aches and pains with nothing definite enough to base a diagnosis on, and came to be looked upon as a chronic grumbler. He died unexpectedly and the autopsy showed an abscess on the under surface of the liver, which had burst into the peritoneal cavity.

While diagnosis is rendered more difficult in old age, the diligent and skilful searcher will be more apt to find the morbid process at this age than any other, because they are more marked, as the dead-room abundantly testifies.

That was a wise saying of Wilks, that "a man is no younger than his arteries." I have already remarked the senile condition is essentially a general atrophy. In this the heart is to be excepted, as it alone of the muscular system is hypertrophied. The causes for this is the lessened elasticity of the arterial walls and the narrowing of the arterial lumen and the deposit in the arterial coats of atheromatous products, requiring a greater force to propel the blood through the vessels. That disease of the circulatory system is the greatest source of danger in old age, is testified to by my table. Of the 950 deaths, 151 were from the various heart lesions, and 67 from cerebral hæmorrhage, 218 in all. Atheroma is the chief disease of the circulatory system, and is often attended by extensive calcification of the aortic valves, interior of aortic walls, and the coronary arteries.

Next to atheroma and its attendant phenomena, fatty degeneration of the heart is the most frequent morbid heart condition of old age. We must here distinguish between fatty degeneration or the change of muscular tissue into fat, and the deposit of fat between the normal muscular fibres. The presence of the arcus senilis is said to be diagnostic of fatty heart. I have never verified this point. A better diagnostic sign is the weakness or absence of the systolic sound which, being mainly produced by muscular contraction, is impaired. Fibroid degeneration also occurs. In this condition the muscular fibres are replaced by fibrous connective tissue. Either form of degeneration produces sudden death, either by rupture of the heart wall or simple paralysis from over distension. I may say in passing that sudden death is nearly always caused by heart failure and very rarely by cerebral hæmorrhage, where, though the hæmorrhage be extensive, the patient may live several hours or even days.

As the lungs are constituted of the most delicate of tissues, we would natural expect marked changes in them in the senile period. The first thing that strikes one on opening the chest of an old person is the marked pigmentation of the lung surface, giving it a mottled black and pink color. This pigmentation is a deposit of carbonaceous particles having been inhaled. The microscope shows a partial disappearance of the alveolar septa causing an enlargement of the alveoli by partial coalescence. This with the fixation of the chest, another senile change, accounts for the emphysema that old people experience on making exertion. Another thing worthy of note is revealed by autopsies made on the bodies of old people, and that is the large number of old tubercular lesions which were not suspected during life. These lesions consist of pleuritic adhesions, old cicatrized foci and scattered gray tubercles. Active tuberculosis is not a prominent disease in old age, and when it exists it is apt to be exceedingly chronic. Of our 950 deaths, there were but 122 from phthisis and fibroid phthisis together. As further showing the truth of this statement the tenth U. S. census showed that of 91,270 deaths from consumption during the census year 25,610 were of persons between 20 and 30, while but 8,222 were over 65. Again of a block of 2,800 examinations—carefully made—for admission to the National Military Home, but 260 were found to have clear indications of tubercular impairment of the lungs.

The statement that "pneumonia is the scourge of old age," made by high authority is not borne out by our figures, as but 37 of the 950 deaths were caused by this disease. Loomis makes the astonishing statement that nine out of ten of those who die after the age of 65, die of pneumonia. Upon what such a statement is based I cannot see. Nor is lobar pneumonia different in any marked degree from the same disease in younger people. The initial chill is not so marked nor is the temperature so high, but the crepitant or more generally subcrepitant rales, the rapid breathing and the solidification are present and would be found if looked for. I never regard the examination of an old person complete, no matter what the trouble until the chest has been examined.

The greater toleration and lessened sympathetic reflexes spoken of before, mask the subjective symptons of the patient sometimes unless the physical examination be made. Neither is the prognosis in these cases much graver unless there is great debility from some pre-existing disease, when pneumonia is but the closing act. Two other facts are worth noting in this connection, one is that defervescence by crisis is rare among the aged; and the other is that muttering delirium is almost prognostic of a fatal termination.

The changes in the alimentary canal are quite as well marked as those in any other part of the body. The teeth are lost; the mucous and peptic glands of the stomach are lessened in number and size; the intestinal villi are fewer and the intestinal wall thinned, except the colon, which is frequently dilated and its walls thickened by the replacement of the muscular tissue by connective fibrous tissue. As a sequence of these changes we are not surprised to find a weakened digestion and poor assimilation of food in these people. Constipation is an almost constant accompaniment of old age. The frequency of cancer especially of the stomach and liver is shown by the large number of deaths due to cancer, 33 out of 384 reported from the Central or Dayton branch alone. According to my own observation the majority of these were doubtless of stomach and liver. Of the various diseases of di-

gestion and assimilation I can say nothing here, as the subject is too extensive. You all know how difficult they are to handle and can subscribe heartily to Abernethy's statement that a man cannot be induced to attend to his digestive organs, till death, or the fear of death stares him in the face." Diarrhœa is a frequent and troublesome disease in old age and sometimes one most difficult to control. As an adjunct to the alimentary canal the liver may be considered here. Fatty degeneration or the "nutmeg liver" is almost always present in senile autopsies. Cirrhosis is extremely rare, which I think remarkable in the face of the generally accepted theory of alcoholism as the chief etiological factor in its causation, since a large number of the men in the military homes are confirmed alcoholics.

Bright's disease, like phthisis, is apt to be chronic with old people and is generally of the fibroid character, and so is likely to go undiscovered, as the symptoms are so masked as to be misleading, and the patient be treated for indigestion, neuralgia, rheumatism, etc. At the risk of boring you I will give the history of one such case in detail: W. R., age 70, had been under treatment for about six months for chronic dyspepsia. Gives history of long-standing rheumatism. Complains of pain in stomach; persistent vomiting and headache and insomnia; no treatment seemed of any avail in relieving his nausea. He was emaciated, abdominal veins enlarged and liver seemed contracted. Repeated examinations showed both albumen and casts, but in moderate quantities only. Patient finally died of exhaustion. Autopsy: Body very much emaciated; lungs œdematous; hypertrophy of left ventricle, valves of left heart and commencement of aorta studded with minute patches of atheroma; liver contracted to little over half its normal size; walls of stomach thicker than normal and more opaque; colon contracted throughout entire length, at some points seemingly almost closed, the coats thick and fibrous; the wall of bladder also thickened and opaque; left kidney contracted and fibrous on section; right kidney larger, but also fibrous, cysts scattered over surface of kidneys, microscopic examination of kidneys shows glandular and epithelial elements crowded and replaced by fibrous tissue; the walls of the arteries thickened and their lumen diminished; 37 of our 950 deaths were caused by Bright's disease. Of the other morbid conditions of genito-urinary tract I need only mention the senile prostate which, with the allied cystic troubles, belongs to the domain of the surgeon.

The most distinctively senile change of all is the degeneration of the brain and nervous system in general. In the brain the sulci become shallower, the gray matter thinner, and the brain as a whole shrinks. This shrinking is compensated for by an increase of the ventricular fluid and the subarachnoid fluid which on exposing the brain surface has an opaline appearance; corpora amylacea appear in the thinned cortex. In the cord and nerve trunks many medullary sheaths disappear, giving the sections the appearance of being full of minute punctures. The conductivity of the nerves is lowered and consequently reflex action is lessened. There is gradual loss of mental power, memory and attention suffering most. An interesting point here is, that the memory for events long passed, is better than for more recent events. The old persons will tell you in tiresome detail events which happened when they were young, but cannot remember what they had for yesterday's dinner. When these changes are exaggerated we have either softening or sclerosis, ending, of course, in dementia; or in the spinal tract scleroses of various ones of the physiological tracts. Of the changes in the nerves of special sense I need not speak.

And now, gentlemen, we will turn from a prosaic, and to me not very satisfactory, picture of the changes of old age, to a pen-picture drawn by a master hand.

"The sixth age shifts
Into the lean and slippered pantaloon,
With spectacles on nose, and pouch on side,
His youthful hose, well saved, a world too wide
For his shrunk shank; and his big manly voice
Turning again toward childish treble, pipes
And whistles in his sound: Last scene of all,
That ends this strange eventful history,
Is second childishness, and mere oblivion;
Sans teeth, sans eyes, sans taste—sans everything."

The Southern Surgical and Gynecological Association will hold its fifth annual meeting in the city of Louisville, Tuesday, Wednesday and Thursday, November 15, 16 and 17, 1892, under the presidency of Dr. J. McF. Gaston, of Atlanta. Members of the medical profession are cordially invited to attend.

TWO PRACTICAL SUGGESTIONS FOR ANALYSTS OF URINE.

By LOUIS FAUGÉRES BISHOP, M. D.

Use a proper specimen glass. Three years ago, when junior assistant at St. Luke's Hospital, I became dissatisfied with all the forms then in use, and, after unsuccessful search for one that was satisfactory, I finally designed one for use in the hospital. This has proved very satisfactory to each succeeding generation of juniors and has been adopted at other hospitals.

The "St. Luke's model" consists of a cylindrical glass resembling that commonly used for taking specific gravity, but larger and constructed with a wider foot and a lip for pouring. The bottom is slightly concave instead of the convex form that the maker naturally gives to such vessels unless warned not to.

The advantages of the cylindrical over the usual conical form are practical and important. The specific gravity can be taken without disturbing the sediment, and the bulk of the sediment can be more easily estimated.

Every hospital interne falls into the habit of completing his analysis, except the microscopic work, and then doing that with greater or less care as indicated by the previous tests. With the conical form of glass this is attended with serious disadvantage, as the urine must be put into another vessel to find its specific gravity. Another disadvantage of conical glasses is that casts adhere to the sides in settling.

The best practical method for estimating the quantity of sugar in urine is by the fermentation of a specimen until the sugar is entirely destroyed, and then determining how much has been disposed of.

Take two four-ounce bottles of urine; cork one tightly; into the other drop one quarter of a cake of compressed yeast (Fleischmann's). Stand in a warm place until the glucose in the latter has been destroyed as shown by Fehling's test. The number of degrees of difference in specific gravity will equal approximately the number of grains of sugar to the ounce of urine.

The specimens might be weighed and the sugar estimated by a simple arithmetical calculation, but the use of the urinometer is really only a simpler method of weighing. The degree-grain ratio expressed above is found to be nearly correct (Roberts).

I have devised the following formula which can be used in the intervals between the estimations in well-marked cases of diabetes: Divide 880 by the number of ounces of urine passed in twenty-four hours. To the result add 1,000, and subtract the sum from the specific gravity of the urine. The result will be the number of grains of sugar to the ounce of urine.

The primary number, 880, may be, for greater accuracy, altered to suit exactly individual cases as determined by experiment.

For example, suppose a patient to pass 100 ounces of a specific gravity of 1.030. $\frac{880}{100} + 1{,}000 = 1{,}008.8$. $1.030 - 1{,}008.8 = 21{\cdot}2$. The patient has about twenty-one grains to the ounce. Now, if in this individual case the result was found to be too far from truth, a suitable number would be substituted for 880, which, though the best coefficient for general use, yet is not so good for particular cases as one that may be determined by experiment.

SAW-WOUND OF THE ELBOW.

A. M. CARTLEDGE, M. D.,
LOUISVILLE, KY.

Several weeks ago a young man while engaged at some work in a saw mill, fell across a circular saw striking his arm, the saw cut extending across the posterior aspect of the elbow joint in a transverse direction splitting down through the olecranon process, and nearly through the condyle of the humerus; the joint proper was not disturbed; at least you could see the action of both bones of the forearm. It was a typical case for ordinary resection of the joint: After, however, examining more carefully, I concluded I would drain the joint and practice a little experimental surgery on it, having such faith in thorough drainage and asepsis. I drew the triceps down, getting the proper approximation, stitching it with about eight or ten sutures to the base of the olecranon process, which had been entirely sawn through; washed it out with 1-5000 bichloride solution, and put the arm up in not quite complete extension, thinking that if ankylosis occurred, I would have an

arm that would have the carrying power developed in a most marked degree. Drainage tube was removed on the tenth day; the dressing I removed on the fourteenth day, that is the second dressing, and was surprised to find the wound nearly healed, pronation and supination perfect.

This case, I think, from a surgical standpoint, is extremely interesting, and, as far as I know it is entirely unique. As I understand, this class of injury is always subjected to resection.

SYMPHYSIOTOMY, WITH THE REPORT OF AN OPERATION.*

By BARTON COOKE HIRST, M. D.

Symphysiotomy has as remarkable a history as any procedure in surgery. Suggested for the first time in the Surgery published by Pineau in 1598, and first performed upon a living woman in 1777, the idea may be said to be three hundred years old, while its practical application dates back more than a century.† From the year of the first operation until 1858 symphysiotomy was performed 85 times in different parts of the Continent of Europe and once in England with a mortality of 33 per cent. The frequency of the operation diminished after the first few years until in 1858 it had practically died out. It was revived, however, in Italy in 1866, and in the succeeding twenty years 70 operations were performed with a mortality of 24 per cent. Italy continued to be the exclusive field of the operation until a year ago, when it was again tried in Paris by Pinard, whose interest in it was aroused by a visit of Spinelli from Italy. Ten operations have since been performed in Paris, two in Dresden, and one in Strasburg. From January 1, 1886, there have been 52 operations with only a single death, due to septic infection before the operation was undertaken. Twenty-three symphysiotomies have been done already this year, and the last 34 women have all recovered.

We owe the introduction of symphysiotomy in this country to Dr. Robert P. Harris, who, as well known, has long been interested in the subject, and at the recent meeting of the American Gynecological Society in Brooklyn read a paper tracing the development of the operation, showing by the most laboriously collected statistics the present brilliant results achieved by it, and demonstrating, by the description of typical cases, its utility in labors otherwise insuperably obstructed by a contracted pelvis.

Ten days after Dr. Harris's paper was read, on September 30th, the first operation in this country was performed by Dr. Charles Jewett, in Brooklyn. Three days later it was again performed at the Maternity Pavilion of the University Hospital in this city.

The position of symphysiotomy is now established beyond a doubt. Its modern revival I believe to be the most important advance in obstetric surgery since the general adoption of abdominal section for the treatment of early extra-uterine pregnancy. It is applicable in contracted pelves with a conjugate over 67 mm., and, therefore, should be the method employed in almost all cases of the kind in this country, for a greater contraction of the pelvis is rarely seen among us. It should, moreover, almost entirely displace the Cesarean section for a relative indication. It is a much simpler, an easier, and a safer operation. This is also the opinion of Leopold, who cannot be accused of prejudice against Cesarean section, with his brillant record in that field.

There is and will be for some time, perhaps, an objection to the operation from those who have had no experience with it, on the ground that sufficient space cannot be thus gained. In answer to this objection is the fact that the pubic bones may gape 7 cm. after their separation, and the statement of Morisani, that the conjugate is thereby increased from 1.3 to 1.5 cm. But an absolutely conclusive answer is furnished by the subjoined clinical records of some typical cases.

*Leopold's First Case.**—A dwarf, 135 cm. tall, with the following pelvic measurements: Sp. il., 22 cm.; cr il., 24 cm.; tr., 28 cm; conj. ex., 17½ cm.; conj. diag., 8¾ cm.; conj. vera, 6¾ cm. She had been delivered thrice previously, twice of dead children, once by the induction of premature labor. After a labor of seven hours and twenty minutes, ushered in by rupture of the membranes, symphsiotomy was performed with the head above the brim. In ten minutes the

*Read before the Philadelphia County Medical Society, October 12, 1892.

†R. P. Harris: Amer. Syst. of Obstet., vol. ii. p. —

*Centralbl. f. Gyn., 1892, No. 30.

child was extracted with forceps. The head was of normal size (transverse, 9¾, 8¼; circ., 34).

*Leopold's Second Case.**—A woman, delivered once before by craniotomy. The pelvic measurements were as follows: Sp. il., 22; cr. il., 25; tr., 30½; conj. ext., 16; conj. diag., 8½; conj. vera, 6¾. Labor began in the evening; membranes ruptured seven hours later; operation three hours later with head above the brim. Extraction of the child in ten minutes with forceps. The head had a circumference of 35¼ cm.

Porak's Case.†—A primipara with rachitic pelvis, conjugata diagonalis being 9.6 cm., and pelvis presenting some asymmetry, very likely from scoliosis. Labor began on June 10th. About twelve hours later the membranes ruptured, and from eight to ten hours afterward the os was completely dilated. The head rested above the brim of the pelvis. Forceps was applied, but all efforts to engage and extract the head failed The symphysis was opened, and the head then extracted "with the greatest ease" by forceps Recovery.

Freund's Case.‡—A woman in labor six days; water drained off for two days. After opening the symphysis the head was delivered in fifteen minutes without instruments. There were two previous deliveries, one of a dead and one of a living child. The pelvic measurements were: Sp. il., 24½; cr. il., 27; tr., 31; conj. ext., 18½; conj. diag.. 10 cm.; conj. vera, 8¼. the child's head after birth was found unusually large and hard. B. T., 10 cm.; B. P., 11 cm.; F. O., 12 cm.; M. O., 14 cm.; S. B., 10 cm Circumference, O. F., 37 cm. Recovery.

Jewett's Case. §—The first symphysiotomy in America, performed by Dr. Charles Jewett, of Brooklyn, September 30, 1892. Woman, a native American, primipara, fell in labor, September 30, 1 o'clock, A. M.; at 10 A. M. the occiput appeared at the vulva, but was held fast by an approximation of the ischiac tuberosities, reducing the bisischiac diameter to three inches. Nine hours later Dr. Jewett first saw the patient. The forceps had been vigorously used in vain Symphysiotomy was performed two and one-half hours later, or eleven and one-half hours after the impaction of the head at the outlet. Delivery was effected by supra-pubic pressure and by shelling the head out with the fingers in the rectum. The woman is now in good condition, but unfortunately the child died twenty-four hours after birth, from the compression to which the skull had been subjected during its long impaction in the pelvis.

The University Maternity Case.—A German woman, aged nineteen, pregnant for the first time, was admitted to the University maternity, September 24th. The examination by the resident physician and the students showed the child to be presenting by the head, the back to the right The pelvic measurements were: Sp. il., 25 cm.; cr. il., 27 cm.; tr., 30½ cm.; conj. ex , 18 cm

The internal examination made by myself just before operation showed the conjugata diagonalis to be 9½ cm.; conj. vera, 7¾ cm. The girl fell in labor Saturday morning, October 1st. The pains, recurring all day, on Sunday became very vigorous. On Monday morning, when my attention was first called to the case, the contraction-ring was high, the uterus stood almost straight out from the body, and the child's head was movable about the superior strait. The membranes were unruptured. By no justifiable degree of force could the head be made to enter the pelvis. The fetal heart-sounds were good. It was evidently, therefore, a choice of Cesarean section, craniotomy, or symphysiotomy. The last was done, with the assistance of Dr. R. C. Norris and the valuable advice of Dr. R. P. Harris, who kindly consented to be present. The child was delivered with forceps in one hour and four minutes from the time the operation was begun. I purposely took my time, for the os was only the size of a dollar, and was very rigid, so that a more rapid extraction would have seriously injured the cervix. Head measurements: B. T., 7½; B. P., 9; F. O., 12; M. O., 13½; circ., 34. Mother and child are well.

The technique of symphysiotomy is simple and easy. After thoroughly cleansing the field of operation and disinfecting the vagina as well, a short vertical incision is made on the abdominal wall, reaching to about three-quarters of an inch above the symphysis. The attachments of the recti muscles are severed just sufficiently to admit one finger. The forefinger of the left hand is passed under the symphysis, and upon this as a guide the curved knife of Galbiati is inserted until its beak projects under and in front of the symphysis. The joint is then cut upward and outward. To avoid injury to the urethra, a metal catheter is inserted and pressed by an assistant downward and a little to the right, while the knife is placed a little to the left; but with Galbiati's knife I should think that there is little likelihood of cutting the urethra or the plexus of veins in its neighborhood. I at first thought that an ordinary probe-pointed, curved bistoury would serve my purpose well enough, but I quickly laid it aside, and was glad to avail myself of Galbiati's knife, an illustration of which is appended, which I happened to possess—at the time one of the three, I believe, in the country.

As soon as the joint has been severed, the wound should be covered with iodoform gauze, and then the child extracted with forceps, or allowed to be delivered naturally, as seems best in the individual case. I should, I think, almost always prefer the forceps. It is well to have the trochanters supported by assistants during the passage of the child through the

*Centralbl. f. Gyn., 1892, No. 30.

‡Millerheim: "Ueber die Symphysiotomie," Centralbl. f. Gyn., 1892, No. 30.

§Personal communication.

pelvis, so that the sacro-iliac joints shall not be injured.

As soon as the delivery is completed the wound is sewed up, the lowest stitch, if desired, passing through the top of the symphysis. How the whole symphysis can be stitched up, as Leopold claims to have done, I do not understand. After closing the wound and dressing it, rubber adhesive strips are placed around the hips and the lower abdomen, and a tight binder applied. The symphysis unites surprisingly soon, and three weeks after the operation the patient can walk as firmly and as well as ever.

There is only one disturbing thought in connection with the introduction in this country of an operation destined to do so much good. The charge of superficiality lies with some justice against us. We are too ready to reach out toward the top without a sufficient basis of solid preparation, and I fear that symphysiotomy may be undertaken by many who cannot correctly measure a pelvis and who have not the experience to decide whether a head can pass through the pelvis in which it is about to enter or in which. it is engaged. There is consolation, however, in the reflection that if symphysiotomy should be done needlessly the results are not likely to be so disastrous as in the case of Cesarean section, which, to my knowledge, was done several times unnecessarily during the excitement produced among medical men by the improved results of the Sänger operation.

SYPHILIS AND GENERAL PARALYSIS.

J. Bonnét, *Thése de Paris,* 1891, (Abstr. in *Schmidt's Jahrb.*) Out of the eighty-one paretics in the Villejnif asylum the author found fifty-four who had certainly had former syphilis, eleven who probably had had it, and six who possibly had. Ten cases were apparently non-sypniletic. He hence considers from 66.6 to 80.2 per cent. thus affected, and concludes that the more carefully we search for syphilis in paretics the more general we find it. Out of one hundred and four other insane patients there were ten certain, four probable, and three dubious cases of syphilis. Bonnet does not conclude that syphilis is the invariable antecedent of paresis, but calls it the most important cause. As adjunct causes he considers alcohol and heredity the most important.

FOREIGN BODIES IN THE CORNEA.*

By EDWARD JACKSON, M. D.,

PROFESSOR OF DISEASES OF THE EYE IN THE PHILADELPHIA POLYCLINIC; SURGEON TO WILLS EYE HOSPITAL.

The history given by the patient, as to a foreign body in the cornea, is often worthless. If the foreign body is but partly imbedded, and the projecting portion hard and angular, so that every movement of the lid causes a scratching of the conjunctiva lining it, the patient, of course, immediately notices its presence, and can give a correct and definite history of its occurrence. But if the foreign body be deeply imbedded so that it does not touch the conjunctiva of the lid, or if it lie with a perfectly smooth surface presenting to the lid, its entrance may not be noticed, or the momentary disturbance caused by it may be so slight as to be forgotten before the secondary effects of its presence draw attention to the eye, and even if those secondary effects are ascribed to it, and the foreign body itself perceived, it may be supposed to have entered the eye at a time considerably later than was the case. Often, however, the patient will, on account of the gradual advent of symptoms of irritation, ascribe them to an entirely different cause.

Again, very many patients come with the impression that a foreign body is in the eye, from the irritation—the sensation of scratching—caused by a simple conjunctivitis. And these, having thought the matter over carefully and repeatedly, can usually tell just when and how the mythical body lodged there. And they even go so far as to accurately locate it, by picking out some spot on the iris not before noticed, and regarding it as the offending object.

For the diagnosis of a foreign body in the cornea we must depend on, what generally is sufficient basis for a diagnosis in diseases of the eye, the results of our examination of the patient. If the foreign body is comparatively large the most casual glance may reveal its presence, but often there is need for special methods and a prolonged search before its presence or

*Read before the Philadelphia County Medical Society, October 12, 1892.

absence is established; and even where its presence is perfectly obvious at the first glance these same methods must often be employed to make sure that we have completed its removal.

In the search for the foreign body the important idea with reference to the illumination of the eye is that it shall be thoroughly under the control of the surgeon, so that he may either strongly illuminate the cornea itself and view it against a dark background of unilluminated iris and pupil, or can illuminate the background, leaving the cornea in comparative darkness, and depending on the interruption of the light from the background, which any opaque foreign body will cause, to reveal its location. This is the advantage that the so-called "oblique" or "focal" illumination in the dark room possesses over inspection by an ordinary diffused light.

The shifting of the point of view so as to bring the foreign body into the area of most favorable illumination is essential to any thorough search, whatever method is employed. By focal illumination foreign bodies of light color will be best seen when strongly illuminated against the black pupil as a background; while if the foreign body is dark it is better to strongly illuminate the iris behind it.

We may get an illuminated background against which a foreign body will usually appear as a black speck by throwing the light into the eye with the ophthalmoscope mirror held several inches in front of it, and shifting the position of the eye or the point from which it it viewed so as to obtain the fundus reflex through the different parts of the cornea.

An excellent model for searching for the foreign body, and one that has the advantage of being available during its removal, is to look for the interruption that it causes in the reflex obtained from the corneal surface. To do this, place the patient facing a window with a large open sky space, while the surgeon takes his position so as to obtain the reflection of the sky space from the surface of the cornea, a very good position being to stand behind the patient, looking down on the cornea. The patient's eye is then turned from point to point, so that the reflection is obtained from all parts of the cornea in succession. If the window with clear sky space is not obtainable, a piece of plain white paper or card-board strongly illuminated, and held close in front of the eye to be examined, will furnish the required reflex from the corneal surface. The essentials are that the reflex shall be bright, uniform, and large enough to enable the observer to go rapidly over the whole cornea without missing any part of it.

If on any part of surface there is an irregularity, as an ulcer or a foreign body, this will cause an interruption of the reflex, and be immediately noticeable. A great help in making such irregularities prominent is the careful drying of the cornea with a little absorbent cotton, a method to the full value of which my attention was called by our fellow member, Dr. M. W. Zimmerman. The removal of all moisture does not impair the reflex from the sound cornea, but lays bare any irregularity or loss of substance, which, when filled with fluid, would give almost the normal corneal reflex.

Another aid to the detection of foreign bodies in the cornea is the use of a solution af fluroescin. A good solution consists of

Fluroescin	1 grain.
Sodium carbonate	2 grains.
Distilled water	1 fluidrachm.

A single drop of this is placed on the suspected cornea, and after two or three minutes the excess is allowed to be washed away by the tears. It is then found that while on the uninjured cornea not the slightest effect has been produced, the corneal tissue in the neighborhood of any recent abrasion has been stained a noticeable light green. This discoloration at once directs attention to the locality of the injury, and the stained tissue furnishes a background against which any foreign body of dark color is more readily seen.

While the reception of a foreign body in the cornea may not be noticed, and during the first few hours the pain and redness resulting from its presence are apt to be quite slight, its continued presence provokes a reaction which increases in severity until it is gotten rid of. At first the redness will be confined to the vessels of the part of the peri-corneal zone nearest the foreign body, and its location will then often guide us to the site of lodgment. Later, it extends until the whole conjunctiva and the deeper tissues of the globe become hyperæmic, when it becomes of little diagnostic value. With the in-

creased vascularity comes increased pain and tenderness.

Self-cure, in the cases of a foreign body in the cornea, takes place by suppuration of the adjoining tissue to such an extent that the softening loosens the foreign body and allows it to be rubbed off by the movements of the lids—a slow, painful process, that probably few persons are solid enough to submit to without seeking competent aid for its removal. In a few cases, however, the inflammation subsides, the foreign body becoming surrounded with fibrous tissue that tolerates its presence, and in rare cases it is possible for a foreign body to remain in the cornea a long time without provoking any reaction. I have met with three cases in which foreign bodies were thus retained for periods varying from one to eighteen months.

Of the removal of foreign bodies from the cornea in general, little need be said. The introduction of cocaine as a local anæsthetic has enormously simplified it. There is, perhaps, some danger now of being led by the passive demeanor of the patient to indulge in unnecessary manipulation of the parts. The thorough cleansing of the actual cavity of lodgment, together with the scraping away of the bruised and lacerated tissue, is very important, but the promiscuous scraping of the neighboring surface in the attempt to catch a foreign body that is not clearly seen is always harmful if not dangerous.

When the foreign body enters with such force as almost to penetrate the cornea, and, to a still greater extent, when it projects into the anterior chamber, its removal becomes an operation of considerable delicacy and importance, on account of the danger of the premature escape of the aqueous humor and the scratching or puncture of the anterior capsule of the lens, causing traumatic cataract.

There applied a few month since, at the Wills Eye Hospital, a young man who had received a small chip of iron in the center of the left cornea the day before. Efforts had been made to extract it with a piece of magnetized steel, and with a penknife, but had been unsuccessful; whether they had driven the fragment deeper I do not know. He applied in the morning, and Dr. Pontius, the resident surgeon, finding that the aqueous was escaping and the anterior chamber shallow, had wisely, simply instilled atropine and closed the eye with a light bandage to secure rest. When the patient returned in the afternoon the swelling of the adjoining cornea had stopped the leakage of the aqueous, and the anterior chamber was of normal depth. The chip of iron was seen projecting from the posterior surface of the cornea into the anterior chamber.

The eye was placed under the full anæsthetic action of cocaine, and a broad, gradually tapering needle introduced at a little distance from the wound, in such a manner that its point entered the anterior chamber close to the foreign body and passed back of it. This point was held against the posterior surface of the cornea, the needle being steadily pressed forward sufficiently to keep the incision full and prevent the escape of aqueous. The foreign body was then dug out with another needle and the ordinary corneal spud. This was attended with the escape of some aqueous, but, with the broad needle held flat to shield it, any injury of the lens was prevented.

In such an operation the placing and steadily maintaining in proper position of the broad needle that acts as a shield is the most difficult part. For this purpose a needle which continues to broaden and becomes blunt and rounded on its edges, so that it ceases to act as a knife and more perfectly performs its function as a plug, might be a slightly better instrument than the ordinary broad needle. In this case the steady maintenance of the shield-needle in position was materially aided by causing the point to reënter the posterior surface of the cornea, and by introducing it in such a direction that the tendency of the patient to move the globe kept it pressed againstthe needle rather than withdrew it.

When a foreign body composed of or containing iron remains a few days in the cornea it is apt to leave a dark-brown ring of staining when it is removed. It is often difficult to decide whether the appearance is due to this stain alone or whether some portion of the foreign body also remains. On this account it is more satisfactory to remove the stain if this can readily be done, but any prolonged or extended scraping is not justified, for the stain is harmless and temporary.

The electro-magnet is of little use in removing foreign bodies from the cornea

because they are so firmly wedged that its force is entirely insufficient to dislodge them. There is, however, a special form of foreign body for which I have resorted to the electro-cautery, namely, grains of gunpowder, which have proven, when the attempt was made to extract them in the method of ordinary foreign bodies, to be so intimately associated with the adjoining corneal tissues as to render it impracticable to extract them in the ordinary way without too much laceration of tissue.

In the case of the patient shown this evening there were three such grains in the left cornea remaining after others were removed without difficulty from both corneas. These deeply imbedded and diffused grains were touched with a pointed electrode, and thus destroyed with the least possible damage to the surrounding tissues. The same method was applied to some of the grains that had been at the same time imbedded in the lids, brow, and cheeks, with the very satisfactory results shown.

VARICOCELE.

Mention of a new plan for the treatment of varicocele, prompts M. M. Latta to say for the last three years I have in three cases adopted the plan of passing an elastic ligature in front of the vas-deferens, but including veins and everything else, much as is done in the treatment of an anal-fistula. It is not intended to have the ligature cut its way out, and it is only left in until it is certain that the veins are occluded. Stout threads are fastened to each end of the elastic cord, and then by the aid of a large Hagedorn needle it is carried in and the ends drawn as tight as is thought desirable, and tied across with a strong thread. The patient must stand up until the ligature is passed. After that it makes no difference what position he assumes. The operation is practically bloodless and requires almost no time for its performance. There is generally some pain for an hour or two, and very little after that. The patient should lie in bed or on a lounge until the operation is completed, which will depend on how tight the ligature is drawn—in my own case it required from eight to ten days. No great length of time is lost, the operation is safe and the cure is permanent.—*Ind. Med. Jour.*

Society Reports.

ALLEGHENY COUNTY MEDICAL SOCIETY.

Scientific Meeting, September 20th, 1892.

J. Chris Lange, M. D., President, in the Chair,

DIAGNOSIS OF TUBAL PREGNANCY BEFORE RUPTURE.

Dr. J. E. Rigg: About April 7th, 1892, I was called to see Mrs. A., aged 34, with the following history: Married twelve years, never had a child, though she miscarried once about seven years ago at from six weeks to two months. At the time I saw her she was suffering severe pain in lower part of abdomen more or less constant. At the last period had not changed to any degree, but had been suffering more than usual with soreness and pain in pelvis.

I may state here that she had suffered a good deal of pain in that locality for years, for which she had frequently sought relief by treatment without success; at this time there was a bloody discharge with more or less shreds of tissue.

Bimanual examination revealed the uterus little if any enlarged, no tenderness, the right tube and broad ligament somewhat enlarged, but movable. I thought it possible that she was pregnant, but could not satisfy myself fully on that point. Leaving an anodyne and ordering perfect quietude, I left for the night. I saw her again daily for three days, when the nurse showed me a piece of animal tissue resembling very closely a part of a placenta, with the statement that the trouble was all over now. Not feeling quite satisfied I mopped out the uterine cavity with a strong etheral solution of iodine. At this time I did not make a bimanual examination. For several days (I think about ten) she was quite comfortable, got up and went about her work, the discharge almost disappearing. I did not see her again until May 13th, when she looked quite pale and exhausted. I ordered her back to bed. She complained that the old pain had returned, but not so severe, and that it would last about three hours in each twenty-four and then be quite easy for the rest of the day; this

would come on each day about four o'clock. I returned, three days later, having been away from town in the meantime, and found about the same general condition.

Not feeling clear as to her condition I made another bimanual examination; at this time I found the apparent thickening in the right tube had developed into quite a distinct tumor, oblong in shape, movable, attached at one end to the uterus, on which it could be moved as a hinge. When drawn away from the uterus it would drag it with it but it could be moved in any other way without affecting it. The shape of the tumor, the fact that it was not inflammatory and attached to the uterus the way it was, and that it had enlarged so rapidly, together with a history of possible pregnancy aud the discharge of what seemed to be placental tissue, which I was now convinced had been the decidua, pain at periods and pinched expression, left little doubt in my mind that I was dealing with a tubal pregnancy.

I informed her of the nature of the growth and asked that Dr. Buchanan see the case, and if he would concur, advised that she be operated on without delay. The following morning Dr Buchanan saw her with me, and concurred in my diagnosis. Accordingly, on the 21 inst., she was opened and the tube removed, it bursting in the delivery. The fœtus was not found, but the placenta was there, well marked. The case did not have any unfavorable symptoms in the process of recovery.

Dr. Buchanan: Dr. Rigg deserves credit for having made a positive diagnosis of extra-uterine pregnancy in this case prior to rupture, and I believe it is the only case reported in this vicinity where the diagnosis was made previous to rupture of the sac and confirmed by the operation. When I was called to see the case, I fully concurred in the diagnosis and a few days later operated. The tube was found to be distended to the size of a large lemon. It burst while being drawn through the incision. The operation was attended by no difficulty and the patient made an uninterrupted recovery. I here exhibit the specimen, ovary, dilated tube and placenta *in situ*.

Diagnosis of extra-uterine fœtation before ruptute is considered by many authorities impossible, but in this case it was positively made by Dr. Rigg before I was called.

Dr. Werder: I must congratulate Dr. Rigg on the correct diagnosis. I was present at the operation and examined the specimen. There was no fœtus in the tube after removal. The question would come up what became of the fœtus. There are two ways in which the fœtus could have disappeared. The first way is the death of the fœtus from some cause and absorption, and probably that is what happened in this case, that is tubal absorption. The fœtus may be expelled into the abdominal cavity and absorbed, and, according to some recent investigations in this matter, I believe this is rather a common occurence. Cases of the former kind terminate not by a sudden shock, as in case of rupture into the abdominal cavity; there is not that marked anæmia accompanying it, but at the same time there are severe pains and cramps. I had intended to demonstrate a specimen which I removed on the 16th of July, from a woman, who was practically moribund when operated on, but the specimen became spoiled and is hardly worth showing. It was a very beautiful specimen; the fœtus was intact and the placenta and tube were also in good condition. The first three or four days following the operation the patient was in very good shape; everything appeared to be promising; but on the third or fourth day diarrhœa commenced, which everything failed to control. She died on the eighth day, from exhaustion. This is the fifth case of extra-uterine pregnancy on which I have operated, and the only case I have lost.

ADVANTAGES OF SYME'S AMPUTATION.

Dr. J. W. Macfarlane: One of the resident physicians to the West Penn Hospital and myself each performed a Syme operation on the patient shown in these photographs. I believe there are few cases of double Syme amputation extant. In addition to the desire of showing you that case, the object in bringing it before you is this: In the report of the transactions of the State Society for 1891, Dr. Allis, in his Address on Surgery, condemns amputations that are done below the so-called point of election. He speaks of Pirogoff's and Chopart's but makes no mention whatever of

Syme's amputation, passes that without a word. Now in Western Pennsylvania at least, Syme's amputation is not only admissible but is considered an excellent amputation; then possibly next to this is Chopart's. Though the latter is often a nice operation and successful, it is not as popular with the profession as Syme's.

I have consulted an artificial limb manufacturer of this city, and he says there is no other stump as good as that furnished by a Syme amputation. The case that you have a photograph of is that of a young man from Beaver Falls, about twenty-one years of age, who was run over by a train. He had his feet on the rails and the wheels passed over them destroying the fore part of both feet. He was detained in the hospital longer than he would otherwise have been, for the simple reason that he had suppuration. It was no fault of ours, however. For the first twenty-four hours he threw himself around, removed the dressings, and finally poured milk over both stumps, and he was so intractable for awhile that we had to put him in a straight-jacket. With Dr. Murdoch's assistance, I did a Syme's amputation on a young man for gangrene of the foot. He refused, when he came in, to have anything done with the foot, and moist gangrene occurred. I saw that patient the other day and he was doing admirably, able to plant his heel firmly on the ground. This young man, before he left the hospital, was able to walk with the aid of two canes. Of course his gait is not artistic, but there is no other stump I know of which would enable him to go around in that way. Dr. Allis stated that it is impossible to walk except as a very old man. That was in eighteen hundred and ninety-one. In ninety-two the matter came up again before the State Society, and Dr. Price, of Philadelphia, who has, in his person, had amputation below the knee at the so-called point of election, went so far as to say that any one who would do an amputation of the foot, should be sued for mal-practice. Dr. Murdoch was present, and I think was able to take care of his side of the case in refuting the doctor. To show the gait of a patient with a Syme's operation, I have brought a case here to night, illustrating the fact that walking can be done right nicely. This patient is one operated on by Dr. Murdoch. I have here some limbs made in this city. This is the leg that is furnished for a Syme stump. You will see it is not so cumbersome as a leg in which you have amputation at the point of election. This is a leg such as would be furnished a man who had amputation at the point of election. There is a stump coming down here about five inches, and a man can walk well with such a limb. You can see quite readily that this is a much more heavy and cumbersome apparatus than the limb for the Syme. A man in such a limb as this can walk very nicely, but that is no reason why Syme's amputation should be under-rated.

I exhibit, also, a smaller limb for a child and one for an amputation through the condyles, and this also makes a very nice stump ; but my chief reason in showing these limbs was to show the difference in the weight of the Syme and the limb for a leg amputation, which is a matter of no small moment to one who has to travel on an artificial limb.

Dr. Buchanan : I cannot let the opportunity pass of raising my voice in protest against the position taken by Dr. Mordecai Price in this matter. I was perfectly astounded when I read of his advocacy of amputation through the leg in all cases where the tissues were destroyed back of the ball of the great toe. I believe such teaching is calculated to do the very greatest harm. When we see a stump such as this and the facility with which this man walks on it I cannot see how any one in his senses could sacrifice a limb up to the point of election.

Dr. Murdoch: This is a subject in which I have taken a great deal of interest, and one which I think is of great importance to everyone who practices surgery. It was the opinion of the older surgeons that when a foot was crushed back of the ball of the great toe, that the leg should be cut off at the point of election. That was the rule until James Syme advised the operation at the ankle-joint. Syme's amputation, the operation that you see has been performed on this young man. The first operation was performed on the ankle-joint in 1842, and after he did it, he said it should supersede amputation in the leg for all injuries to which it was applicable, injuries in the foot, and it has superseded amputation in the leg ever since, in the minds of all surgeons, in all countries, I believe, excepting the surgeons of Phila-

delphia, and I believe no voice has ever been raised against Syme's amputation until this opinion has been proclaimed by the surgeons in Philadelphia. ' Now, in 1887 I made an address before the State Medical Society when the meeting was held in Williamsport. I had the honor to deliver the address on surgery, and in that paper, which is published in the volume of transaction for that year, I went through the subject so fully I feel it would not be worth while for me to go into it again. It is a pretty large subject, but when any one, because he wears an artificial limb himself, claims thatSyme's amputation should be abandoned and all operations of the foot back of the ball of the great toe, I contend that he has said something which is absolutely absurd; and when he adds to that, that any man who makes amputation at that point should be prosecuted for malpractice, he says something that is foolish. We all know that the danger to life after amputation increases as we approach the trunk. On the point alone the foot amputation should be favored. I have in this city a colored man upon whom I did a double Chopart amputation. It is not an operation so universally approved as the operation of Syme, but I contended in the paper to which I have referred, that in certain cases where a good flap can be secured, the operation of Chopart, preserving the heel, is preferable to Syme's amputation. This colored man is a cook and walks with nothing on his foot, merely stuffing the forepart of the shoe with some rags. He puts on ordinary shoes and walks about his kitchen the same as I would, and he is able to walk a couple of miles with no other assistance than a cane. In some cases Chopart's operation is not a success, because the foot is drawn up. Syme's amputation is considered a very favorable one in Pittsburgh. I know of patients who walk better than this man and stamp on the heel and jump from a chair striking with the full weight on the end of the stump. Where the hard tissues are preserved, as in Syme's amputation, the face of the stump is so covered with the thick tissues of the heel that it perserves a better stump and is about the only one on which the patient can bear the weight of his body. I do not think anyone would think of amputating immediately above the ankle joint, as it is certainly better to go up to the calf. A professional man, such as Dr. Price, who does not do hard work and merely walks about the city, can carry a heavy limb such as this; but to a working man, its very weight is a great disadvantage, to say nothing of the cost of repair, which is as much in a year, according to Dr. Price, as the repairs of his buggy. I do not believe it is right for surgeons to be governed altogether by opinions of instrument makers. It is for the instrument makers to make artificial limbs, as you see it can be done, for those men who have suffered amputation at the joint. I think every right-minded man who will consider the subject, must conclude that amputation at the ankle joint is preferable to one in the middle of the leg.

Dr. Daly: I want to take issue with Dr. Buchanan on one statement, that is, that the statement attributed to Dr. Price is calculated to do harm. I do not believe that any one who would make such a statement would do harm to anybody but himself. I do not believe that members of the profession, the younger members especially, would pay any attention to the opinion of Dr. Price. I believe it has been demonstrated in other places than here it is an excellent amputation. I have seen five or six in various hospitals, but I have yet to see a Syme's amputation that is not very good and useful in its results to the patient.

Dr. R. H. Grube opened the discussion of the paper announced for the evening, entitled "The Pathology of Old Age." (see page 648).

Dr. Koenig: Dr. Grube has said if I understood him correctly, that the condition in old age is one of atrophy. That undoubtedly is correct, but it seems to me there is something behind that which is responsible for the final condition. All vital phenomena in the human, as well as in all other living organisms, may be referred to certain attributes possessed by protoplasm, and instead of atrophy it would seem more definite to refer the condition characteristic of old age to diminished protoplastic irritability. There are apparently in the human life, about three periods of vital activity. During the first period constructive metabolism is very strong, and exists in the normal life for about twenty-five or thirty years, during the period of growth, the period of childhood and adolescence. Then during a

period of perhaps twenty years more or less, there is an equilibrium between the destructive and constructive metabolism. The forces are just about able to hold each other level; the wear is repaired every day by the constructive action. Then gradually after that the tissues are not fully repaired and the protoplasm itself doubtless gradually undergoes a retrograde action and irritability and other attributes decrease, so when we have pneumonia in the aged the protoplasm in the cells of the brain does not respond to the influence that is sent there from the injured lungs in which the pathological condition is very different from that observed in the case of young persons where the reparative processes are active, nor do we have the symptoms that exist during the early part of life.

In the third stage the organism gradually breaks down more and more and the repair is less and less until finally in very old age the condition characteristic of the new born is almost reproduced, with all the functions of the protoplasm arrested, resulting in a physiological death. I remember one case of this kind in an old man up in the nineties who gradually lost his special senses, both blind and deaf, recognizing his friends by the sense of touch alone. Before he died the nutritive process became so impaired that gangrene of his toes set in. In this condition he lingered for a few days till, in my opinion, the unexcreted product of tissue change, so poisoned his enfeebled nerve centres that death became a natural result.

Dr. Murdoch: I think the word degeneration is much more appropriate as expressing the changes in the tissues from old age than the word atrophy. It is a wise saying that "a man is no younger than his blood vessels," and it would be wise to say that a man is no older than his blood vessels and nerves. There are a few expressions used in medicine that are calculated to make us all very weary, such as bowel trouble, lung trouble, etc. I have no doubt these things are very troublesome to patients, but it seems to me that the terms, like many others in use, are very much misapplied. There is another term to which I object and that is heart failure. I do not think anybody can make a success of dying without heart failure. It is altogether too vague and meaningless, but I must confess myself to its occasional use.

Dr. Daly: In the female I have noticed a certain indication of approaching age and one that she cannot conceal very well. I refer to the appearance about the mouth and under the jaw. The tissues become flabby, the mouth can no longer assume the air of pouting lips; and these are the points that women who depend so much upon their personal appearance to make them attractive, such as actresses, desire most of all to overcome. I have been consulted more than once by actresses of world-wide fame. They had watched the on-coming appearance of senility, and while the skin covering their body was plump, the submaxillary tissue, which is flabby, hangs down. They would give anything to have that made plump again. Now, with the man, I do not know how you can judge as to his years. I do not think gray hair an indication of old age. Some day I expect to be old myself, and I have been watching for the appearance of old age in other men.

Dr. Lange: I would like to have a few remarks only on some terms which have come in the discussion this evening, which I have always been unable to understand. The words vital-affinity, vital-irritability and vital-susceptibility which were used this evening and frequently appear in books are used to designate what occurs before degeneration and atrophy. Now, it seems to me, gentlemen, that these are terms to which we, as physicians, and even as pathologists, ought to object. We do not know what vitality is. Vitality is a mystery and must remain so to us. Vital-susceptibility and vital-irritability and vital-affinity! I do not believe that there is one gentleman here who understands what those terms mean. I am sure I do not, and I have tried hard to find out. As physicians, these terms should be ignored by us. We can go no further back than to say that atrophy and degeneration are for the most part characteristic diseases of old age, and, therefore, the lesions upon which we can put our fingers and prove, but we can prove nothing beyond these lesions. Now, it is a matter of course that when we have degeneration of a tissue that there is something back of this, but in some cases we cannot say, and as I believe that nobody knows what is back of this lesion which is demonstrated, I think it is as far as we can be expected to go to name the lesion.

In regard to pneumonia, I agree with what has been said, that pneumonia in old age travels very insidiously. However, as the term pneumonia without qualification always gets into the discusosin, there remains the unfortunate fact that pneumonia appears in so many forms, from a bronchitis to a passive pneumonia and all the intermediate stages and degrees, that when pneumonia is mentioned unqualified it is hardly possible to know of what one is speaking. Post-mortem examinations even often fail to decide whether it was bronchitis or pneumonia, so intimately connected are these two.

DR. KOENIG: I want to say in response to the last speaker that protoplasmic irritability is no myth but an established fact. It is our duty to go beyond superficial symptoms in our investigations of subjects of this character, not only is this duty imperative on pathologists but likewise on the general practitioner of medicine.

DR. DALY: Degeneration is not necessarily followed by atrophy as witness the case of senile enlargement of the prostate gland. Other cases might be cited.

DR. GRUBE: I accept Dr. Daly's suggestion that degeneration would have been the better word to use where I used the word atrophy. At the same time I agree with Dr. Lange's statement that atrophy usually goes with degeneration. As for Dr. Murdoch's remarks on heart failure, I cannot agree with him that it is a fad. We use that term now as we formerly used the term paralytic stroke, indicating now the result of cerebral hæmorrhage. Heart failure where the person drops dead, nine cases out of ten, is simply a heart failure. The heart is dilated and from some start or strain distends the right ventricle and the heart stops. I do not know of any better term and I think nine times out of ten it is the cause of sudden deaths.

GASTRO-ENTEROSTOMY.

DR. WERDER: This specimen is from a case that was operated on by me last November and we obtained the organs after her death six and one-half months later. Nothing would remain in the stomach for three months before operation. To remedy this gastro-enterostomy was performed and all the food passed through this artificial opening connecting the stomach with the small intestine. The six and one-half months she lived after the operation, she lived in perfect comfort and suffered no pain whatever. She lost about one pint of blood shortly before her death, and I think that was the immediate cause of the fatal issue. Three days before she died she walked about one mile. She suffered intense pain before operation, and she was in bed three months before she was operated on.

DR. BUCHANAN: I had the pleasure of assisting Dr. Werder in this operation and I must say that the patient was in such a low condition that it was very questionable, when the operation was begun, whether it could be completed. After the condition within was discovered it was questionable whether it was justifiable to enter on the gastro-enterostomy, but the operation was completed in a very short time. I saw her afterwards and she was apparently in a perfectly normal condition. I think this is the first operation of the kind that has ever been performed in this part of the state.

EXPLORATORY LAPAROTOMY.

I would mention in this connection a case that I operated on shortly after this. An old man had a very large cancer of the stomach but had no vomiting. The diagnosis of the case was that of omental growth, and he was operated on because he was losing flesh and because of the rapid increase of the growth of the tumor. When the abdomen was opened the condition was discovered as being that of a large cancerous growth in the stomach, and the patient was in such a low condition that, although I was prepared to perform gastro-enterostomy, I did not consider it advisable to do so, because he had no symptoms of obstruction and because I did not think he would be taken off the table alive. This man simply had an exploratory incision, and recovered from the operation but died on the thirteenth day of obstruction due to the fixation of the growth by adhesion to the incision, which prevented the free movement of the stomach. This occurred after he began to take solid food. I do not think that I have ever heard of this accident happening after an exploratory operation in cancer of the stomach.

THE MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, September 16th, 1892.

The President, Dr. F. C. Simpson, in the Chair.

Dr. S. G. Dabney read a paper on "Myxoma of the Nose and Fibro-Myxoma of the Naso-Pharynx." (See page 645).

DISCUSSION.

Dr. Wm. Cheatham: I believe the Doctor forgot to mention the effect of nasal polyps upon the antral and other sinuses; their presence may be cause or effect, in affections of the sinuses; by stopping communication between the nasal cavity and these sinuses, thus preventing the interchange of gases, an inflamation of the sinuses may result; or again they may be the result of sinus inflammation and by their presence, may prevent a cure. The Doctor's paper is a good resumè of the subject to date.

Dr. J. M. Ray: Dr. Dabney has given us a very good resumè of polyps and their formation. It has been my experience to see polyps quite frequently in children. I remember that McKenzie especially calls attention to the fact that these growths are not apt to occur in children. In the last two or three years I have had several cases under twelve years of age. The last experience I had with growth of this character was in a child under fourteen.

As to the form of growths that project into the naso-pharynx; I believe that primarily they are the same thing as an ordinary polyp, growing backward into the naso-pharynx, developing rapidly and taking on a fibrous condition. I have removed several of them. I presented one to this society some time since, which was a very large cyst quite as large as a guinea egg; it filled up the entire post-nasal space. I have often seen these growths project out into the throat having undergone fibrous degeneration, being hard and dry. I believe they are simply misdirected nasal polyps developing to a greater size, and in that way becoming the so-called myxo-fibroma of the naso-pharynx.

Dr. Chilton: (of Dallas, Texas) I have enjoyed Dr. Dabney's paper very much. The remarks in regard to bone degeneration in some cases of myxomata, cause me to recall a case I had several years ago: When I saw the patient he had not been breathing through his nose for twelve years. I examined him time and again, and there was absolutely no bone trouble whatever. I removed, I think, eight or ten polyps, and the man recovered under treatment very nicely and that has been six or eight years ago. It has been my experience to find no bone trouble in these cases. I have been paying especial attention to cases of this character for some time, and have never seen any bone degeneration.

As to the benefits of after treatment, I have found that in nearly all cases there is a recurrence of the polyp without after treatment. In fact, you always find some pathological condition which is unquestionably the cause of these polyps, and the liability to recurrence is very great.

Dr. W. L. Rodman: I would like to ask Dr. Dabney how common sarcomatous polyp is in the post-nasal space; that is how often he has seen them.

Dr. S. G. Dabney: I only remember having seen one case of sarcoma in the nasal passages. But it is a well known fact that the tendency of fibroma is to undergo degeneration, becoming sarcomatous in character.

Dr. J. M. Ray: I want to ask what proportion of cases of multiple nasal polyp are permanently cured by operation, or any after treatment. In my experience where the polypi are multiple, they will recur in spite of any treatment, before or after removal.

Dr. S. G. Dabney: Referring to Dr. Cheatham's remarks: There is no question but the condition he mentions does sometimes occur, but I have never encountered it in my experience. I believe Bosworth reports having seen several cases of that kind.

Notwithstanding the fact that McKenzie says nasal polyps are very rare in children, my experience has been very much like that of Dr. Ray in this respect. I have seen three or four cases in children under twelve or fourteen years of age.

In regard to the point made by Dr. Chilton about bone disease: My observation is that the bone is very often diseased in cases of multiple and long-standing nasal polyp, but not otherwise. I do not think, however, that the occasion for removing the bone is because of necrosis, but the removal of a small portion of bone is

often necessary to reach the base of the polyp.

It is hard to say just what proportion of the cases are permanently cured. Dr. Ray's question is a very pertinent one, and is very hard to answer, as patients are often lost sight of by the attending surgeon.

(Drs. Ray and Cheatham state never having seen a case of multiple polyp permanently cured).

Dr. T. C. Evans: In regard to the recurrence of nasal polyps: There are some cases that I have had under observation ever since I have been doing special work (four or five years) in which they have not returned. The cases I have under observation, however, were single polyps. I do not believe these are as apt to recur as in cases where there are several. I remember one case particularly which I operated upon three years ago, where both nasal cavities were filled with polyps hanging down in the post-nasal space; they were all removed and up to six months ago there had been no recurrence.

PATHOLOGICAL SPECIMENS

Dr. A. M. Cartledge: No. 1. This specimen is only interesting from the rapidity of it growth. It was removed from a young man twenty-four years of age, two weeks ago last Monday. The history of the case is about as follows: Two years ago he commenced having pain in the left leg, deep seated pain but no swelling. This continued until several months ago, then there was some swelling. His physician who treated him in the country consulted a surgeon at that time, and there seemed to be nothing more than just a simple enlargement of the vessels with slight swelling. An incision was made down through the periosteum, and the trouble at that time was thought to have been, I believe, a diseased condition of the bone, together with necrosis and periostitis. After this incision the tumor took on a very rapid growth, and within three weeks attained the size which you see here. It is decidedly malignant requiring no microscopical section to prove that; one has been made, however, proving that it is sarcoma. I made a careful examination and advised immediate amputation at the thigh, which was done as stated two weeks ago. The patient left the infirmary in fourteen days from the time of amputation; there never was any suppuration, and he went home yesterday.

No. 2.—The next two specimens I want to exhibit are especially instructive, showing two forms of ovarian disease. One being a very large hydrosalpinx removed from one side, and a pyosalpinx removed from the other. There was acute ovaritis on the right side, with a small abscess on the left. Tube on the right side was fully as large as a sausage; adhesions were very dense; operation done about eight weeks ago. I report it not so much for the specimens as the subsequent course of the case. There was considerable hæmorrhage, and, owing to this and on account of the large amount of peritoneal surface exposed, I treated it as I have treated several cases very successfully, by packing in a large quantity of gauze in strips, not only for the purpose of drainage, but for the purpose of hæmostasis. In six hours from the time of operation the patient's temperature was 102½° F.; in twelve hours temperature had gone up to 103° F.; pulse very rapid; pain severe. She died in eighteen hours after the operation with this high temperature. On holding a post-mortem of the case it was found that the alarming symptoms were due to intestinal obstruction, although there had been very little tendency to vomiting, but there was rapid sinking and a little loop of the bowel had become incarcerated in the gauze that was packed in. I do not think the value of gauze packing in cases of this kind, where you have extensive adhesions and a great deal of blood, should be underestimated; I am satisfied it has saved cases for me in a good many instances; I have packed in great quantities of it in bad cases without causing any trouble. I shall continue to rely upon it in these cases, yet, in this case, it was the cause of death.

No. 3.—The patient from whom this specimen was removed was referred to me last Saturday by Dr. Scott; case referred to him by a physician in a distant city. Diagnosis had been made of pyosalpinx of the left side, and patient was sent here for operation. The woman to look at her seemed to be in fair health, color and expression good, she was a small woman and not much emaciated. On examination by the bi-manual method I determined that the woman was suffering from pyosalpinx, but was not inclined to think the disease was very extensive. The his-

tory was that she had a child about five years ago, and that three years ago she had a miscarriage with retained placenta; her physician, after the placenta had been retained for several days, performed an operation. After this she developed high fever and was in bed three or four months. Since that time she has only been able to be up a little while at a time without becoming exhausted; has been in bed the greater portion of the time. Diagnosis of pyosalpinx was then made by her physician, and she was sent here for operation. When she arrived temperature was about normal. Last Saturday I did the operation, and found the most extensive pyosalpinx that I have ever encountered; there was a great deal of pus; the adhesions were very strong and dense. I never saw anything to equal it. The left ovary and tube had to be separated from behind the uterus, and a great deal of pus escaped into the pelvic cavity. The right ovary and tube were very much enlarged and enlongated; there was also an abscess on that side containing about a half pint of pus. The cavity was thoroughly irrigated, glass drainage tube being used. The discharge from drainage tube was clear serum by Monday and was removed Monday afternoon. The patient was quite weak, pulse going up to 130. She has done uninterruptedly well, however, since the operation, has no pain. Sutures were removed to-day, abdomen perfectly flat, and there has been no further rise in temperature.

No. 4.—The next case I think is of especial interest. Patient a woman thirty-five years of age, and gives about the following history: Five or six years ago she had an attack of severe pain coming on suddenly about the stomach—referable particularly to the stomach and somewhat to the right side. Her husband who is a physician thought it an attack of bilious colic. He called a consultant, who differed with him, however. He searched the evacuations for two or three days after this, but was not rewarded by finding any evidences of biliary calculi. The woman grew better, the pain entirely passing off. From this time up to the present she has been having these attacks of intense pain, lasting anywhere from three or four hours to a day or a day and a half, and during these intervals several times her husband examined the stools but was never able to find any gall stones. The patient had been examined by several physicians, and diagnoses made of gastric colic, gastritis, etc.; there never was any jaundice whatever. One week ago last Wednesday she had a very severe attack, and her husband found it necessary to give chloroform to control the pain, also large doses of opium; this continued all day Thursday and Friday. Dr. Scott saw the case in consultation on Saturday afternoon, and upon examination discovered an enlargement in the region of the gall bladder about the size of a fist, and thought the trouble was in the gall bladder. I saw the case in consultation with him on Saturday night, made a very careful examination, found abdomen very tender, pain still intense, patient taking dangerous doses of morphine. I perfectly agreed with Dr. Scott with reference to the location of the trouble, and we decided to operate Monday. On Monday in the forenoon we did the operation of cholecystotomy, making an incision two and one-half inches in length over the liver, going through the peritoneum; on opening the peritoneum it was found that the gall bladder was covered throughout its anterior surface with a thin margin of liver; this was raised up—while it was movable to a certain extent, there were some adhesions on the lower surface. The gall bladder, on account of its great distension, had to be aspirated and we drew off about two ounces of greenish looking mucus, which seemed to be mixed with pus. I then made an incision into the gall bladder and searched for stones. Seven large stones were removed, one being embedded deep in the cystic duct, which was removed with some difficulty. From the time of the operation the woman did well, had no further pain excepting for an hour or two, temperature never rose above 99° F. She is now up and the fistula gives evidence of rapid closing. On the second day after the operation I gave the patient an enema, and a mucus cast fully thirty inches in length and as large as your finger came away with the evacuation.

Dr. W. L. Rodman: The first specimen shown by Dr. Cartledge I take it is undoubtedly sarcoma, probably of the round cell variety. I do not think that anything has particularly been added to the history of sarcoma of the long bones, since the paper written by Dr. S. W. Gross, in 1880;

he made it clear at that time, that sarcoma of the long bones was most liable to occur in persons from twenty-four to twenty-eight years of age. They run a very rapid course as a general thing. I think Dr. Cartledge gave this man the only chance of his life: that is, going above the growth and removing by amputation.

Dr. Cornelius Skinner: In regard to the second and third cases reported by Dr. Cartledge and his treatment for the hæmorrhage after removal of the specimens exhibited, after breaking up the adhesions, etc., I have employed the gauze-packing in a number of cases and have never had any trouble such as he mentions, neither have I ever seen anything of the kind reported before. I would like to ask if he put this gauze loosely in the cavity, or packed it in solidly. The bowel will sometimes slip down in packing this gauze, and you can see how the gauze could be lapped over the bowel without being observed, and that more gauze put down over the top of that would constrict the bowel, the bowel slipping in between the packing. This packing should be done with a great deal of care, and our attention having been called to the accident, will, of course, make us still more careful in these cases.

This also opens another question—the treatment for abortion. One of the cases I believe had aborted, and in which the operator had attempted to remove the placenta after a certain delay. I think the result proves that these cases should be let alone; that no instruments should be used, and that the uterus should be left to expel the placenta in the natural way.

In the treatment of ovaritis and salpingitis—the cases reported leave us about as much in the dark as before. The ques- that is attracting attention just now is when should we operate, whether in the primary attack, or wait until the second or third attack, or until pus forms. About a year ago I had a lady under treatment for an attack of salpingitis; thought at the time there was pyosalpinx and so expressed myself, recommending an operation for removal of the tube, (which however, was not performed,) and saying that the woman would never give birth to any more children—she was already mother of two. Dr. Huitt saw the case with me and agreed that there was pus in the tube as it felt quite large; also agreed with me as to the prognosis concerning child bearing. Last Saturday, after all of this prognosis, I delivered this woman of a healthy boy baby. However she carried this child with a great deal of discomfort all through the nine months. She did not have one day of comfort in all the time, was not able to go out of the house. There was nothing of this kind in the two previous pregnancies. I never could find out just what it was that excited this inflammation.

By M. B. WERNER, M. D.

M. G. Houzel (*Le Bull. Med.* Sept. 21, 1892) contributes the following: In cases where uterine cancer is confined to that organ alone vaginal hysterectomy is indicated; if however the disease has invaded the neighboring organs to such an extent as to make total extirpation impossible, palliative surgical treatment should be tried. In order to control the hæmorrhage, pain, and sepsis from auto-infection—he uses for his operations a bistoury, curette, and scissors, and discards all caustics, except the occasional use of the red hot iron. He removes all degenerated tissue as far as possible in and around the uterus, at the risk of entering the peritoneum, bladder, or rectum, always in that case uniting as far as possible the edges of those cavities with sutures, and claims primary union. If however this is impossible he packs with antiseptics—preferably lactic acid solution.

His observations have proved that if cancer is left to nature its course is usually as follows: From twenty-five to thirty-five years, death between eight and fifteen months; thirty-five to forty-five years, death between ten and twenty-four months; fifty to sixty years and later, death between twenty-five and thirty-six months.

Those cases treated palliatively by Houzel resulted as follows.

Twenty-five to thirty-five years operated after eight months' duration, survived thirteen months giving a total of twenty-one months.

Thirty-five to forty-five years, operation

* Translated for Medical and Surgical Reporter.

after ten months' duration, survived twenty months giving a total of thirty months.

Fifty to sixty years, operation after twenty-two months' duration, survived twenty-two months giving a total of forty-four months.

These results led him to conclude that when cancer had developed so far that total vaginal extirpation ceases to be justifiable, the life of the patient can be prolonged and made more comfortable by the palliative operative treatment.

Salipyrin is credited with producing good results in profuse and painful menstruation, exception being made in those cases of grave inflammatory changes. It is usually given at the beginning of the period, and its results are more satisfactory than any of the Secale preparations regarding the loss of blood and duration of the period.

Intestinal occlusion from a collection of ascarides, Dr. Paul Simon-Nancy, *Rev. Med. de l' Est.*, 1892.—Child æt. 11, lost consciousness owing to pain located below the umbilicus; there was vomiting and constipation; three days later temp. 38° A. M. and 39° P. M.; face pale, tongue slightly coated, abdomen somewhat distended; a localized swelling can be felt immediately below the umbilicus, which is painful upon pressure; on the fourth day an enema was followed by a slight movement, accompanied by bilious vomiting, which lasted during the night. Sixth day, abdomen more tender to touch, bilious vomiting still continues, have been several movements of pure blood, pulse 128, temp. 38°. Seventh day, child retains nothing; is constantly groaning; facies hyppocratica. During the night, several intestinal hæmorrhages; rectal examination reveals nothing abnormal.

An artificial anus was formed by Heidenreich, a large quantity of liquid fecal matter was discharged, followed by an immediate collapse of the distended abdomen; the day following seven living ascarides were discharged in a mass, and a little later an eighth. The second day after the operation there were five movements through the physiological opening. Santonin was given resulting in a discharge of three more worms, it was then remembered by the attendants that previous to the child's illness one worm had been discharged by the rectum and several had been seen in the vomited matter the day previous to the operation. The artificial anus was closed and healed promptly. Simon cites five other cases extracted from literature. Among these six cases, four have occurred among children. Simon was the first to operate and the only one who saved the case. Clinically the symptoms are those of invagination.—*Deutsch. Med. Zeit.* No. 76, 1892.

Dr. Langermann (*Deutsch Med. Zeit.* No. 75, 1892) reports a case of ligation and resection of the femoral vein, beneath Poupart's ligament, just above its conjunction with its longer branches. Recovery. Operator was Dr. Biedert—Patient, æt. 55, had been operated five months previously for carcinoma of the labia majora, at the same time an enlarged gland had been removed from the left inguinal region. Two glands enlarged to the size of a hen's egg appearing again in this place necessitating the second operation, one of these was deeply adherent, was intimately connected with the saphenous and femoral veins, making it necessary to resect the femoral vein 2½ cm. The wound was drained and closed, the limb elevated. Some swelling and depression of surface temperature existed the first evening which disappeared permanently the next day. The patient was discharged cured one month after the operation. She died later from a metastasis in the lungs. microscopic examination of the resected portion of the vein showed carcinomatous degeneration in its walls, and contraction of its lumen. The satisfactory recovery in spite of the artery remaining untouched Langemann explains by the fact that previous pressure on the vein by the growth, favored collateral circulation, thus avoiding continuous œdema and possible gangrene.

M. Doyen—(*Le. Bull. Med.*, Sept. 21, 1892) presents the results of 305 operations on the uterus and its adnexa. Of these there were 175 laparotomies, 122 vaginal operations, eight laparotomies, intraperitoneal:—Fifty-six cases tumors of the ovary, 1 death (75 years, broncho-

pneumonia); 13 cancerous degeneration of peritoneum with ascites, 5 deaths; 60 disease of the adnexa, 6 deaths—2 due to septic catgut; 30 extraperitoneal hysterectomies, 3 deaths; 1 hysterectomy, reduction of the pedicle, 1 death; 10 hysterectomies, total extirpation, abdominal, 1 death; 5 suppurating fibroids, uncompleted, 5 deaths; 10 vaginal hysterectomies for cancer, 4 uncompleted, 6 deaths; 22 operations for intrauterine growths (polypi)—incision and removal by piecemeal, 1 death; 8 finally requiring section.

The present status of surgery of the gall-bladder as viewed by Prof. Czerny. (*Deutsch. Med. Wochen.*, 1891): I. Operation for gall stones is indicated as soon as there are repeated or continuous attacks of colic. II. Empyema of the gall-bladder, if repeated troublesome symptoms present themselves, calls for operation. III. The typical operation for stone in the bladder consists of an incision, evacuation of the cyst and suture. The abdominal wound should be drained for a short time. IV. Should the ductus cysticus be impermeable, the gall-bladder inflamed, its contents markedly changed, a temporary biliary fistula should be established. V. Extirpation of the gall-bladder is only called for in grave forms of inflammation or carcinomatous degeneration. VI. In closure of the ductus choledochus an operation is absolutely indicated, provided the strength of the patient permits it, should it be impossible to remove the obstruction (stone or abnormal bend in canal) and the establishment of a fistula between the gall-bladder and duodenum is indicated. VII. The triangular (hackenförmiger) incision is in the linea alba, the horizontal immediately beneath the umbilicus, direction toward the right. VIII. The mortality of these operations is lower than that for stone in the bladder.

Careless obstetrics ending in death, (*Zeitschr. f. Medizinal beamte*). Dr. Rump of Osnabruck was called to a case of transverse presentation; he performed version and apparently extracted with ease a partially asphyxiated child. The midwife at once made efforts to restore the child in an adjoining room. On returning she found the doctor apparently engaged in removing the placenta. The mass he drew out seemed to her more like a piece of intestines, but which the doctor insisted to be a portion of the membranes, and ordered the midwife to cut them. The midwife kept the severed portions and found after careful cleansing and inspection that it was a portion of the intestines. The patient began to suffer pains and died soon after. The doctor had left her after writing a prescription. A subsequent post-mortem examination revealed a vaginal tear of 10 cm. through which 17 cm. of intestine protruded. The ascending and transverse portions of the colon were missing the edges showing a clean cut; the piece kept by the midwife supplied the missing portion.

Under legal examination the physician declared that failing in his efforts to replace the prolapsed intestines, which had become cold, he feared gangrene and thought it best to cut the prolapsed portion, and unite the edges with sutures, the condition of the patient, however, became alarming, he concluded to let matters remain as they were. In his opinion the patient died of shock induced by the pains and excitement of labor. The physician was sentenced to six months' imprisonment for careless practice resulting in death.—*Deutsch. Med. Zeit.*, No. 74, 1892.

Dr. Messner (*Archiv. für Patholog., Anat. und Physiol.*, 1892) gives a most interesting case of apparent hermaphroditism. Patient is thirty-one years old and has been married as a husband for seven years. The general form of the body is that of a female but the visible genitalia are those of a male. He shows sexual passions toward the female sex, but not toward the male sex. His first copulation was with a girl, when he was nineteen years old. As husband, he now performs his sexual functions and his wife has given birth to one child. He has emisio seminis, but Dr. Messner was unable at the time of a microscopical examination, to discover any spermatozoa. For the past ten years he has also shown regular menstrual periods every twenty-eight days. On one side he has a well developed testicle; on the other side his sexual gland is not so large.

It is to be hoped that the surgeons will keep track of this monstrosity, and when he dies, will furnish us with the exact anatomical details which could not be satisfactorily given from examination during life.

Abstracts.

THE CÆSARIAN SECTION IN PLACENTA PRÆVIA.

Dr. W. H. Ford (*American Gyne cological Journal*) says: The dangers of placenta prævia, as well to the mother as to the child, are due to thedevelopment of the placenta upon the lower segment, *and* to the *canalization* of this segment during labor.

While the first of these conditions cannot be avoided, the second should not be permitted in placenta prævia totalis, or partialis. Delivery should be by Cæsarian section.

In placenta prævia marginalis, if the circumstances were favorable, the os easily dilatable, the condition of the mother and child good, the head presenting or capable of being readily brought to engage, and the hæmorrhage arrested or moderate, it would be well to follow the method of intra-uterine and vaginal tamponade, and deliver by forceps if the child should be in danger. But if the os were rigid, the hæmorrhage profuse, the presentation lateral, the cord prolapsed and not reducible, or the *fœtus evidently suffering*, I would have immediate recourse to the Cæsarean section.

The Cæsarean section should be performed as soon as the diagnosis is established and the condition of the mother permits, to the exclusion of all other methods, as an elective and primary operation, in all cases of *placenta-previa-totalis* and *partialis*, and in placenta prævia-*marginalis* as soon as the conditions warranting it have been satisfactorily determined.

In the two graver forms of placenta-prævia the Cæsarian section should be practiced as a prophylactic measure, in place of any attempt to deliver by the natural passages, after the first hæmorrhage.

In cases where hæmorrhage is late or sets in only as labor begins, and where, consequently, the placenta is most probably attached laterally, it is advisable, until this entire subject has been practically studied, to deliver per vaginam, as a rule. If, therefore, the cervix be easily dilatable, and the hæmorrhage moderate, we may proceed as suggested in the more hopeful cases of marginal implantation. But *even here*, an undilated os associated with severe hæmorrhages would constitute a very serious condition. If the rigidity were due to fibrosis, it should be abated by multiple incisions; if to carcinoma, the radial Cæsarian section would be indicated. If the cord were prolapsed and after reposition still descended, the os being partly dilated and not dilatable, dangerous hæmorrhage continuing meanwhile, the Cæsarian section would be unquestionably indicated for the safety of both mother and child.

TREATMENT OF PNEUMONIA.

Dr. Jos. D. Craig, (*Albany Medical Annals*, for October, '92) in a discussion on the treatment of pneumonia, concludes that while it is a self-limited disease, it is unsound practice to permit a case to run its allotted course, without such medical means as will give relief. He sums up the indications for treatment as:

1. Prophylactic.
2. Hygienic.
3. Systemic, as regards,

(*a*) The period of invasion with chill and rise of temperature, and the danger from heart and lungs.

(*b*) The fever and its consequences.

(*c*) The cerebral symptoms.

(*d*) The period of crisis.

(*e*) The dyspnœa.

(*f*) The cough and consolidated portion of lung.

(*g*) The exhaustion and weakness.

Dr. J. H. Mitchell, in same discussion says: That each case requires treatment according to its own individuality. He recommends, bleeding, antimony opium, and alcohol. It is no one remedy, but the proper combinations that give best results.

Dr. Wm. Hunt recommends a dressing of a thin layer of cotton, applied over the affected side, secured with collodion, then add layer by layer, until a good padding is secured Thus, the fatigue and discomfort, of frequent poulticing is avoided.

Dr. A. J. Van Vranken in same discussion is a strong advocate of the use of large quantities of alcohol, even going so far as to say that if he were to be confined entirely to the use of any single drug, he would invariably choose alcohol. The amount to be given, in every case depends on its severity. While it is of use in the

first stage, its greatest virtue exists in the second stages. Its use must be pushed until the patient is convalescent.

Dr. Lorenzo Hale says that when a diagnosis is made, we should bear in mind that we are dealing with an infectious constitutional disease, which runs a typical course. Death, in this disease, is always due to insufficiency of the heart which demands first attention. We should employ early and cautious treatment, to prevent collapse; for this condition he recommends venesection; most alarming symptoms, will quickly yield to general bleeding, then clinch the advantage gained by the use of stimulants, which he claims, are always in demand, when the first sound of the heart is feeble, the pulse slow and compressible and the respirations becoming more rapid. If for any reason, alcohol cannot be used, such stimulants as ammonia, camphor, opium in small doses, strychnine and nitroglycerine, can be used.

He regards digitalis, as the great cardiac stimulant and restorative but in extreme danger, we should not wait for its action, but resort to quicker remedies, as the nitrites, ammonia, hypodermics of ether, brandy or strychnia.

For the fever, he believes in letting it alone, unless it becomes excessively high, when he recommends small doses of acetanalid, or antipyrine. For nervous and cerebral symptoms, should they occur. if reduction of temperature does not relieve them, he recommends the cautious use of narcotics. Meningeal complications should always be regarded as grave.

EXTIRPATION OF THE SUPERIOR MAXILLA AND THE CHEEK.

Dr. Frank Hartley, in the New York *Medical Journal*, of October 8, reports a case, in which he removed the superior maxilla. The patient, aged sixty-six years, first sought relief from what appeared to be a wart upon his cheek, below the infra-orbital margin, which gradually increased in size, until it finally involved the greater part of the cheek.

A complete extirpation of the growth was attempted. It required the complete removal of the superior maxilla and cheek. Skin-grafts were taken from the thigh and used to cover the surface. The recovery from operation and the healing and union of the grafts were uneventful. The patient remained in the hospital two and a half months, was discharged with instructions to return in one year, for plastic operation, if no return of disease occurred. On May 15, the operation for the purpose of closing the large cavity, was done.

A large flap of skin, six by eight inches, was taken from the neck and turned upon itself, so as to have the skin take the place of the mucous-membrane, in the oral cavity. The suturing of this flap was accomplished by uniting the edge of the skin, which now took the place of the mucous membrane of the oral cavity, to the inner edge of the furrow surrounding the original cavity, and made by the removal of a strip three-eighths of an inch wide. Catgut sutures were used and skin grafting was made use of to cover the surface expressed by the flap. The solution used was six parts of chloride of sodium, in one-thousand parts of boiled water. The union of the flap to the surrounding tissue as well as the skin grafting, was a complete success.

The case is of interest, on account of the extensive removal of tissue, the successful skin-grafting over bone, and the formation of the whole cheek.

PUERPEAL SEPTIC RINFECTION.

Dr. W. P. Manton, in an address delivered at the twenty-third annual meeting, of the Detroit Academy of Medicine, September 13, 1892, said: Puerperal septic infection, is rarely met with to-day, save as manifested in the occasional case by the temporary rise of temperature within the first few days post-partum.

The rapidly fatal poisoning, due to the sudden entrance of an overwhelming quantity of toxic material into the general circulation, has well nigh passed into history and the young accoucheur, who can add such a case to his experience sees that which, in the not distant future will be considered one of the most infrequent of puerperal complications.

The employment of antiseptics and increasing knowledge of the pathology of septic processes, have almost driven from the lying-in room a host of secondary effects of infection, which formerly were prevalent. Phlegmasia-abba-dolens, (milk-leg) is now a comparatively rare occurrence; septic ulcerative endocarditis is seldom if

ever seen now by the general practitioner, and metastatic complications, in distant organs have become of less interest because of their uncommonness.

The practice of obstetrics, has been revolutionized in less than half a century. Its advance from year to year has kept pace with its sister art and science, surgery. We, who to-day stand on the verge of the millenium of midwifery, can barely appreciate that dark and terrible era, through which our forefathers fought toward the light of knowledge and success.

Medical history offers no more interesting, or instructive page than that on which is recorded the evolution of the obstetric art.

Selected Formulæ.

CONSTIPATION.

℞ Aloin.....1-5 gr.
Ext. bellad.....⅛ gr.
Ext. nux vomica.....¼ gr.
Papoid.....iss gr.
M.—Ft. pill No. 1. (Use no water to form mass.) (Keep in air-tight vials.)
Dose, one pill once or twice a day.

CONSTIPATION.

℞ Ext. cascaræ sagradæ fl.....
Glycerinæ.....āā..f ʒ i M xx.
Aquæ, qs. ad.....f ʒ ij.
M. et Sig.—ʒ i. at bedtime to a young infant.

When the stools are hard and clay-colored, the following has been recommended by Ringer:

℞ Resinæ podophylli.....gr. i.
Alcoholis.....f ʒ i.
M. et Sig.—1 or 2 drops on sugar t. i. d. to infant one or two months old.

TRAUMATIC TETANUS.

Dr. Mayer, of Amberg, reports a cure from the use of a mixture containing in each dose:

℞ Muriate of morphine.....1-65 gr.
Chloral hydrate.....1½ grs.
Bromide of sodium.....2¼ grs.
Sig.—To be taken three to six times a day.

Fifteen grains of morphine were taken in all.

RHEUMATIC BRONCHITIS.

℞ Sodii salicylatis.....ʒ vi.

THE
Medical and Surgical Reporter

ISSUED EVERY SATURDAY

EDITORIAL AND BUSINESS OFFICES:

29-35 N. Tenth St., Cor. Filbert, Philadelphia.

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, OCTOBER 22D, 1892.

THE OPERATION OF SYMPHYSIOTOMY.

The sudden advocacy of symphysiotomy in this country indicates the progressive tendency in medicine. Within a short time the operation has been performed three times by different operators, once in Brooklyn and twice in this city, thus gaining recognition after a period of neglect covering the history of obstetrics in this country. In looking into the question as to the occurrence of suitable cases co-incidentally in the hands of these different operators we are lend to wonder at the causes which have influenced the profession to adopt this new departure. For this we must look first to the results obtained in the present year by European operators, and, secondly to the influence upon the progress of medicine in this country of the German writers. The resumption of symphysiotomy as a modern operation is to be credited to the Italian school, but its promotion in this country was delayed until we were given the results of the recent German workers in this field, namely, Leopold and Freund. The former of these operators has produced a deep impression upon his followers by his commendation of this procedure, on account of the stand which he has until recently taken in favor of Cæsarean section. His attitude will, therefore, strengthen the position of those who believe that symphysiotomy can replace Cæsarean section.

If after careful consideration symphysiotomy is accepted in this country it will probably have the effect of limiting the number of sections, for two reasons; in the first place because of its comparative simplicity and second on account of its claim upon the non-professional world for humanitarian reasons. The cases in which Cæsarean section is indicated will always remain distinct from those in which symphysiotomy is called for.

Symphysiotomy may prove a restriction to the growing leniency toward the Cæsarean operation for "relative indications," perhaps, also, to the frequency of craniotomy. There may be a danger of drifting into a too frequent resortto this simple operation to save the child, in the belief that we are entailing but a slight risk to the mother. There is still a greater danger of this new operation becoming a "fad" with notoriety-seeking specialists whose "brilliant work" has supplied monumental marks in the history of modern abdominal surgery.

In the hands of judicious surgeons the procedure may be of use, and we hope that the subject will receive the fullest attention; not that it may unwisely increase the surgical tendency in obstetrics, but that it may lead to more exact study of indications and to greater care in the early management of cases at the hands of the profession..

Book Reviews.

A Manual of the Operations of Surgery for the the use of Senior Students, House Surgeons and Junior Practitioners. Illustrated. By Joseph Bell, M. D., F. R. C. S., Edin. Seventh Edition, Revised and enlarged. Edinburgh: Oliver & Boyd, Tweeddale Court. London: Simpkin, Marshall, Hamilton, Kent & Co. Price, six shillings.

This work has been rewritten and brought up to date. The different operations are described in a simple and concise manner, all reference and discussions are carefully omitted. The chapter on eye operations is well written and worthy of careful study.

One thing noticeable, that the author says nothing concerning antisepsis or wound dressing.

The work is nicely bound and printed.

The Principles and Practice of Bandaging, by G. G. Davis, M. D., Assistant Demonstrator of Surgery, University of Pennsylvania, etc. George S. Davis, Publisher, Detroit. Price, Cloth, $3.00.

The author claims that the best results in surgery, especially fractures, can only be obtained by understanding the principles and the thorough application of the bandage.

The work is thorough and clear. The fundamental principles are plainly set forth. The art of skillfully applying bandages, should be acquired by every student. This work serves as a practical guide. The book is profusely illustrated.

Mental Diseases; Epitome of; including their Classification, Synonyms, and Symptoms, their Etiology, Diagnosis and Treatment, with the Present Methods of Certification of the Insane, by James Shaw, M. D., formerly Medical Superintendent, and Co-Licensee, Haydock Lodge Asylum, London.

Its Semi-Dictionary form of compilation makes its ready reference exceedingly convenient for practitioners and students and forms a valuable introduction to the more comprehensive treatises and exhaustive monongraphs. The work is largely a compilation from the bibliography of the subject, yet the author has stamped his own individuality as a specialist upon the book by observations and experiences both in Asylum and private practice. Its several chapters are devoted to:

I. Definitions of Insanity and Classification of Mental Diseases.

II. Index of Symptoms Somatic, Physiological, and Psychical, with the Mental Diseases in which they occur.

III. Index of Mental Diseases with their Synonyms and Symptoms.

IV. Etiology. V. Diagnosis. VI. Prognosis.

VII. Pathological Anatomy, Pathology, and Pathogenesis.

VIII. Therapeutics and Hygiene.

IX. Legal Regulations and Forensic Psychiatry. General Index of 23 pages.

One octavo volume. Illustrated. Uniform with Medical Classics. Morocco cloth. Price, $2.75. Published by E. B. Treat & Co., 5 Cooper Union, New York.

BOOKS RECEIVED.

THERAPEUTICS.

THE TREATMENT OF STAMMERING.

For some reason or another the treatment of stammering has never received the attention it merits at the hands of the profession. Its victims are left to fight their way as best they can, and should they dream of better things they are fain to apply to one or other of the quacks—this is, perhaps, a harsh name to apply to some of them—who profess to cure a distressing and disabling infirmity. It is, indeed, a reproach to the medical profession that the treatment of a functional defect of this kind, in the majority of instances, more or less amenable to rational measures, should have been abandoned to outsiders. A good deal has been written with respect to the etiology of stammering, but it is obvious that the want of coordination between the different factors of articulate speech may result from an imperfection in any one of them, and the possible causes of stammering are thereby multiplied almost indefinitely. The least promising cases are evidently those in which the embarrassment is due to what one may term an intellectual chorea. Even in these, however, immense improvement is possible by combined mental and physical training. Moreover, the psychological deficiency is often more apparent than real, and may merely be the result of years of exaggerated self-consciousness created by a ridiculous defect. In other cases the coordinating centre seems simply to get out of gear. An attack of whooping-cough or measels, a fright or other strong emotion, may determine a hesitation which can only be overcome by a course of training. We have recently had an opportunity of witnessing some really remarkable and prompt "cures" of stammering in both children and adults by suitable training, and these results fully justify the claim we have advanced for a greater share of attention.—*Medical Press.*

TETANUS CURED BY TETANUS ANTITOXIN.

E. Pacini (*Rif. Med.*, January 7th, 1892) reports a cure of traumatic tetanus by the tetanus antitoxin of Tizzoni an d Cattani (see *British Medical Journal*, January 2d, 1892, p. 25). A man, aged 21, slightly wounded the tip of his left ring finger with a reaping hook in a stable where there were some oxen, rabbits, and a goat. He washed the wound with wine and tied a piece of rag around it, continuing to do his work as before. About ten days after the accident, which occurred on October 25th, he began to feel some difficulty in opening his mouth, and on November 12th he was admitted to the Hospital of the Colle di Val d'Elsa (Tuscany) with well marked tetanus. He was treated with chloral (6 to 8 grammes in the twenty-four hours, in 2-gramme doses) for some days, but as the symptoms became more severe, a supply of antitoxin was procured from Professor Tizzoni, of Bologna, and, the chloral treatment having been suspended for some hours, 25 centigrammes of antitoxin, obtained from the blood serum of a dog which had been artificially rendered refractory to tetanic infection, were injected hypodermically at 10 a. m. on November 19th. This was repeated at 4 p. m. the same day. In the evening the patient was quieter, the convulsions being less violent, and he was able to open his mouth for about half a centimetre, and to move his head a little. The wound had by this time completely cicatrized. The injections were repeated twice daily on November 20th, 21st, and 22nd. From that time the symptoms became gradually less severe, but it was not till December 9th that the patient could be discharged, being then entirely free from trismus and spasms, and complaining only of some difficulty in opening his mouth, and slight aching along the spine and in the lower limbs. From the report of the case, which is given in great detail, the effect of the antitoxin does not appear to have been very well marked till after the eighth injection. The number of tetanic spasms, which had been 296 in the twenty-four hours on November 19th, 505 on the 20th, 304 on the 21st, 358 on the 22nd, fell to 174 on the 23rd, to 130 on the 24th, and so on by the regular descent, with slight interruptions, to 1 on December 5th. On two occasions during the antitoxin treatment (November 20th and 21st) when the spasms were particularly violent, chloral was given in 2-gramme doses, and after the discontinuance of the injections a similar draught was given every night. With this excep-

tion no treatment is recorded as having been employed after November 22nd.—*Brit. Med. Jour.*

MEDICINE.

THE VALUE OF ALBUMINURIA AS A MEANS OF DIAGNOSIS.

In a paper on this subject in the *International Medical Magazine* Dr. F. R. Sturgis, of New York, concludes from a survey of the literature that albumin in the urine does not necessarily signify any renal disease; that it exists temporarily in many diseases unassociated with any organic renal complication; that from the uncertainty of tests and methods of testing it loses a great deal of its value as a diagnostic sign; and that if present in even a small quantity it is a danger-signal, and if persistent indicates some serious organic lesion.

THE ETIOLOGY OF EPILEPSY.

Walton and Carter (*Boston Medical and Surgical Journal,*) have made a study of the connection between epilepsy and infantile convulsions. By careful scrutiny and elimination of doubtful cases, they were able among two thousand five hundred and thirty-nine cases of all kinds applying at the neurological department of the Massachusetts General Hospital, to isolate one hundred and thirty-three cases of epilepsy —5.25 per cent. In time of onset, they were divided as follows: From birth to five years, twenty cases(15 per cent.); from six to ten years, eighteen cases (13.5 per cent.); from eleven to fifteen years, twenty cases (15 per cent.); from sixteen to twenty years, nineteen cases (14.33 per cent.); from twenty-one to thirty years, thirty-five cases (26.33 per cent.); from thirty-one to forty years twelve cases (9 per cent.); from forty-one to fifty years, three cases (2.25 per cent.); from fifty-one to sixty-five years, four cases (3 per cent.); unknown two cases (1.5 per cent.). Of seventy successive cases of pure epilepsy in hospital and in private practice, in which careful inquiry was made as to the occurence of convulsions in infancy, both in the patient and in brothers and sisters, nine commenced in infancy and became continuous, fifty-six presented no history of convulsions in infancy followed by a period marked by an absence of convulsions. It was found that among the brothers and sisters of epileptics, convulsions in infancy were more common than among the epileptics themselves. Of one thousand children consecutively taken at random from society, Walton and Carter elicited a history of convulsions in infancy in one hundred and eleven. It has been estimated that there are about six epileptics in every thousand of population; as convulsions in infancy are observed in one of fourteen cases (five in seventy) of epilepsy, the two affections occur coincidently once in not less than 2000 individuals; and as convulsions in infancy are observed in 222 of every 2000 (111 in 1000) individuals, fhe chance that a chlld presenting convulsions in infancy will develop epilepsy later in life is 1 in 222. The conclusion to be arrived at is that epileptics are at least not more likely than others to have had convlusions in infancy, and that conversely, a child that has had convulsions in infancy is not more liable than any other to develop epilepsy later in life, after a period marked by freedom from attacks has removed the case from the class of epileptics in which the convulsions begin in infancy and become continuous.

SURGERY.

THE SURGERY OF THE TONGUE.

In an excellent paper on this subject read before American Surgical Association, May 31, 1892, Dr. Danbridge presented the following conclusions:

1. Sufficient experience has been accumulated to show that removal of cancer of the tongue prolongs life, adds to the comfort of the patient, and further affords a reasonable hope of permanent cure.

2. All operations should be preceded by an effort to secure thorough disinfection of the mouth and teeth.

3. In the treatment of continued ulcers and sores on the tongue, caustics are to be avoided and all sources of irritation removed.

4. Persistent sores on the tongue should be freely removed by knife or scissors if they resist treatment.

5. When the disease is confined to the tongue, Whitehead's operation should be employed for its removal.

6. In this operation the advantage of preliminary ligation of the lingual artery

is not definitely settled, but the weight of authority is against its necessity.

7. The advantage of leaving one-half the tongue in unilateral disease must be considered undetermined, but the weight of positive experience is in its favor. In splitting the tongue into lateral halves, Baker's method of tearing through the raphe should always be employed.

8. A preliminary tracheotomy adds an unnecessary element of danger in the removal of the tongue in ordinary cases.

9. When the floor of the mouth has become involved or the glands are enlarged, Kocher's operation should be employed, omitting the spray and preliminary tracheotomy.

10. Removal of the glands by a separate incision after the removal of the tongue, must be considered insufficient.

11. Volkmann's method still rests on individual experience. Its just value cannot be determined until it has been subjected to trial by a number of surgeons.

12. Thorough and complete removal should be the aim of all operations, whether for limited or exteme disease.

13. By whatever method the tongue is removed, the patient should be up and out of bed at the earliest possible moment, and should be generously fed.—*Journal of the American Medical Association.*

A SIMPLE AND ECONOMICAL FORM OF TRACHEOTOMY TUBE.

A very efficient tracheotomy tube for use after the tract has become fairly free by wearing a silver tube for two or three days, can be made with a piece of India rubber drainage-tube in the following manner: An oval piece is cut out of one side of the tube, the shorter diameter of the oval reaching about half way around the tube. Two longitudinal cuts are then made, one on the same side as the oval opening and the other opposite to it, reaching from the end of the tube to a point about a quarter of an inch from the opening; this distance will, however, vary with the depth of the wound that the tube is to be inserted into. In the lateral flaps made by these longitudinal incisions holes are cut for tapes. The piece of tube beyond the oval opening is the part which is put into the trachea. This tube has the following advantages: 1st. It fits the trachea well, having an angle instead of a curve, and tilting of the lower end cannot occur to cause pressure and ulceration. 2d. The window allows laryngeal respiration to take place as soon as the diminution of the swelling has made the glottis patent. 3d. The cost of the tube is practically *nil*. 4th. Being made of drainage-tubing it is nearly always at hand.—(*Brit Med. Journal*).

REMOVAL OF THE VERMIFORM APPENDIX IN THE APYREXIAL STAGE OF PERITYPHLITIS.

Dr. Kümmell read an article at the Surgical Society of Hamburg (*Duetsche Med. Wochenschrift*, No. 11, 1892), in which he reported six cases in which he had removed the vermiform process. The author believes that the remote cause of a perforation is a catarrhal inflammation, and that fecal-calculi, etc., are secondary to this. As a consequence of the inflammation a stricture is developed; behind this a cavernous dilatation occurs, which becomes filled with fecal matter and pus, and finally ruptures, permitting the escape of the contents into the peritoneal cavity. In four of the six operated cases perforation had taken place.

1. The first case was a woman who had had many attacks and was never free from trouble. The appendix was ulcerated in two places. The vermiform appendix and cecum were resected. The patient was dismissed cured.

2. A female patient who had suffered from many attacks. The appendix was removed; the patient was dismissed cured.

3. A male patient who had passed through two attacks before the operation. The case was an unfavorable one, because the perforation was situated at the opening of the appendix into the cecum. The vermiform process ruptured during the operation. The wound in the cecum was closed; but the patient suffers constant annoyance, probably from adhesions which have formed.

4. In this case, a male patient, the perforation was located at the same point as in the last. The sutures did not unite, and a second union was necessary. The patient afterward contracted typhus, and is still under treatment.

5. A woman, 40 years old, who had four attacks. An exudation was distinctly recognizable. The vermiform process was removed. Perforation had not yet

taken place. The patient was dismissed cured.

6. A man, 38 years of age, who had had fifteen attacks. A stricture of the appendix was distinctly recognized, and behind it, a small fecal stone. The case is now in a fair way to recover.

McBURNEY AND APPENDICITIS.

Dr. McBurney, in reportiug a number of cases of appendicitis to the New York Academy of Medicine again calls attention to the comparative frequency of the trouble. Its assumed rarity in former years is explained by the fact that the disease was not understood. Foreign bodies, fæces and other sources of irritation easily set up inflammation. A moderate rise of temperature (99–101) occurs with a feeling of nausea, followed by vomiting. There is abdominal pain, often diagnosed as mere colic, and tenderness of the more or less rigid abdominal muscles. The point of greatest tenderness is found over a spot about two inches from the superior anterior iliac spine on a line extending from this point to the umbilicus. (Our readers will know that this is briefly referred to as the McBurney point.) On deep palpation a tumor may often be felt marking the seat of impactive swelling and inflammation. Suppuration ordinarily takes place; although under hot applications, opium, etc., the attack may be soothed down. The abscess is surrounded by a more or less developed pyogenic wall. Exacerbations may come and go, but with perforation death is sure to come. Primary operation interference is always indicated; delay means inviting uncontrollable danger The most urgent cases are those of acute suppurative disease with perforation and gangrene of the appendix. The diagnostic signs pointing in this direction are: *sudden* severe pains on second day over McBurney joint; rapid subsequent rise of temperature, existence of a palpable sensitive tumor. Ordinarily an incision 4½ inches long should be made about one inch outside of the linea semilunaris. Examine carefully the caput coli; remove all pus; ligate appendix and disinfect with cautery; pack with antiseptic gauze and recovery is rapid and undisturbed.—*New York Medical Record.*

NEWS AND MISCELLANY.

As a recent notice in this journal has informed our readers, the Eleventh International Congress will meet in Rome, Italy, from September 24th to October 1st, 1893. By an official letter dated August 22nd, 1892, and signed by Prof. Guido Baccelli, president, and Prof. E. Maragliano, secretary general, Dr. A. Jacobi, of New York, has been directed to form an American Sub-Committee. Its membership is not yet complete, but on it are already found besides that of the chairman, the names of Drs. Wm. Osler, of Baltimore; S. C. Busey, of Washington; N. S. Davis, of Chicago; Charles A. L. Reed, of Cincinnati; Wm. Pepper, of Philadelphia; F. Peyre Porcher, of Charleston; James Stewart, of Montreal, and Alexander J. C. Skene, of Brooklyn, N. Y. In the interest of facilitating the trip to Italy, and reducing the expense, arrangements will be made with the steamship companies. According to a communication from the Central Committee—contained in a letter of the secretary general's dated September 14th—the North German Lloyd proposes to reduce the fare to Genoa twenty per cent., and that of the return trip by ten per cent. It is expected that still more favorable terms will be secured.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY FROM OCTOBER 9, 1892, TO OCTOBER 15, 1892.

Leave of absence for one month is granted Captain Henry P. Birmingham, Assistant Surgeon, U. S. Army.

Leave of absence for fifteen days is granted Major Daniel G. Caldwell, Surgeon, U. S. Army.

By direction of the Acting Secretary of War, paragraph 3, S. O. 199, Aug. 24, 1892, A. G O. is revoked and Captain Louis M. Mans, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Apache, A. T., and will report in person without delay, to the commanding officer, Whipple Barracks, Arizona, for duty at that station.

1st. Lieutenant Isaac P. Ware, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Logan, Colorado, and will proceed without delay to Fort Supply, Indian Territory, and report in person to the commanding officer of that post for duty.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.

(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up" This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.

(WM. R WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.

(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.

(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . . 1 gr. | Concentrated Pepsin 1 gr.
Ext. Nux Vomica . . ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{600}$ gr.), Codeia ($\frac{1}{60}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonial from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of th profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that th applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

86 Maiden Lane, **New York City**

Doctor, are you Losing Money?

I MEAN, do you lose sight of old bills? Do you have trouble to prove your claims? and do you fail to get in all your charges because your system of accounts is faulty?

When a patient asks, "How much do I owe you, Doc?" can you tell him exactly in ten seconds? No? Then you are not using Dr. Walker's "Complete Book of Records," and you need it. Just out; new idea; perfect; cheap. All manner of accounts complete in one book; original entry. You may see sample pages and learn all particulars, at the expense of one postal card, by sending your name and address to Keystone Publishing Co., Philadelphia. Do it to-day.

Before the Medical Profession almost 30 years, and invariably gives uniform satisfaction.

We respectfully ask thorough testing, strictly UPON ITS OWN MERITS, to prove the exceptionally high reputation it holds

Owing to correspondence on the subject, we regret being compelled to caution that inferior Coca preparations are frequently substituted upon patients, and, as we do not advertise to the public, physicians will kindly be particular to insist on

VIN MARIANI

FORMULA: "VIN MARIANI" is the concentrated extractive of the fresh leaf Erythroxylon Coca, blended with a special quality of Bordeaux Wine. Each half-litre bottle contains the medicinal properties of two ounces of selected leaves.

DOSE: Usually a wine-glassful three times a day, half an hour before meals or immediately after. Increased or diminished, at discretion of the Physician.

INDICATED: As a pleasant, mild stimulant, without unpleasant reaction; a diffusible tonic; a strengthener of the Nervous system, with especial good effect on the digestive and respiratory organs; convalescence and enfeebled conditions. Effect is immediate and lasting.

NOTE: Extensively used in Hospitals, Cliniques and private practice, its merits are recorded by the medical press of Europe and America. Uniform excellence and recognized efficacy won the absolute confidence and esteem of every physician who subjected it to test, and it may be affirmed that wherever Coca is indicated "Vin Mariani" invariably receives the preference.

The continual increasing demand is a clear proof of the reliance placed in "Vin Mariani" by the Medical Profession, through whom it has been popularized.

WE WILL BE HAPPY TO FORWARD, POST-PAID, TO ANY PHYSICIAN MENTIONING THIS JOURNAL, A HANDSOMELY BOUND BOOK, DETAILING FORMULÆ, DOSE, PHYSIOLOGICAL EFFECTS AND THERAPEUTIC INDICATIONS OF COCA, AS ALSO OTHER INTERESTING READING MATTER CONNECTED WITH THE SUBJECT BY EUROPEAN AND AMERICAN OBSERVERS.

MARIANI & CO.,

Polyclinic, Lombard Street, above Eighteenth.

MEDICAL DEPARTMENT OF THE COLUMBIAN UNIVERSITY.

WASHINGTON, D. C.

ANNOUNCEMENT, 1892—'93.

The Seventy-first Session will begin October 1st, 1892, and continue seven months. Graded three year course required. Ample clinical facilities.

FACULTY:

J. F. THOMPSON, Surgery.
W. W. JOHNSTON, Practice.
A. F. A. KING, Obstetrics.
E. T. FRISTOE, Chemistry.
WM. LEE, Physiology.
D. W. PRENTISS, Therapeutics.
D. K. SHUTE, Anatomy.
H. C. YARROW, Dermatology.
G. B. HARRISON, Pediatrics.

THEO. SMITH, Bacteriology.
T. E. McARDLE, Minor Surgery.
H. L. E. JOHNSON, Gynæcology.
G. N. ACKER, Pathological Histology.
W. M. GRAY, Normal Histology.
W. K. BUTLER, Ophthalmology.
S. RUFFIN, Medical Jurisprudence.
C. W. RICHARDSON, Laryngology and Otology.
A. C. PATTERSON, Mental Diseases, Hygiene.

For circulars, address **A. F. A. KING, M.D., Dean,**

1315 Massachusetts Avenue, N. W., Washington, D. C.

UNIVERSITY OF PENNSYLVANIA.

MEDICAL DEPARTMENT.

THE 127TH ANNUAL WINTER SESSION will begin Monday, Oct. 3d, 1892, at 12 M., and continue 7 months.

THE PRELIMINARY SESSION has been discontinued; the Spring Term begins early in May, 1893.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology; with bedside instruction in Medicine, Surgery, Gynæcology and Obstetrics, are a part of the regular course and without additional expense.

☞With the session beginning October 2, 1893, a four-year compulsory course will be instituted.

FACULTY:

WILLIAM PEPPER, M. D., LL. D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M. D., Professor of Gynæcology.
JAMES TYSON, M. D., Professor of Clinical Medicine.
HORATIO C. WOOD, M. D., LL. D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M. D., LL. D., Professor of Chemistry and Toxicology.
JOHN ASHURST, JR., M. D., Professor of Surgery and Clinical Surgery.
EDWARD T. REICHERT, M. D., Professor of Physiology.
WILLIAM F. NORRIS, M. D., Professor of Ophthalmology.
BARTON COOKE HIRST, M. D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITERAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Anatomy.
JOHN MARSHALL, M.D., Nat. Sc. D., Assistant Professor of Chemistry.
LOUIS A. DUHRING, M.D., Professor of Diseases of the Skin.
JOHN S. BILLINGS, M.D., LL.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

DR. JOHN MARSHALL, Dean,

36th and Woodland Avenue, Philadelphia.

WESTERN PENNSYLVANIA MEDICAL COLLEGE.

Medical Department of the Western University of Pennsylvania.

THE REGULAR SESSION begins on the 20th of September, 1892, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon three regular courses of Lectures is requisite for graduation. A three years' graded course is provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, 1893, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which address the Secretary of Faculty, Prof. T. M. T. McKENNAN, 810 Penn Ave.

Business correspondence should be addressed to

PROF. W. J. ASDALE, 2107 Penn Ave., Pittsburg.

THE BALTIMORE MEDICAL COLLEGE.

Preliminary Fall Course began Sept. 1, 1892.
Regular Winter Course begins October 1, 1892.

Excellent Teaching Facilities, Capacious Hospital, Large Clinics.

Send for catalogue, and address

DAVID STREETT, M. D., Dean,
403 N. Exeter St., Baltimore, Md.

WALNUT LODGE HOSPITAL

HARTFORD, CONNECTICUT.

Organized in 1880 for the special medical treatment of

ALCOHOL AND OPIUM INEBRIATES.

Elegantly situated in the suburbs of the city, with every appointment and appliance for the treatment of this class of cases, including Turkish Bath, Russian, Roman, Saline and Medicated Baths. This institution is founded on the well-recognized fact that INEBRIETY is a DISEASE and CURABLE.

Applications and all inquiries should be addressed

T. D. CROTHERS, M.D.,

Sup't Walnut Lodge, Hartford, Conn.

Definite Chemical Products

OF SUPERIOR THERAPEUTIC VALUE.

CHLORALAMID (Schering).

HYPNOTIC.—Dose, 15 to 45 Grains. A full descriptive pamphlet (64 pages) supplied on request.

PIPERAZIN (Schering).

URIC ACID SOLVENT. Will dissolve at least twelve times more uric acid than lithia. Dose, 15 Grains per day, with continuous treatment. Pamphlet (32 pages) sent on request.

PHENOCOLL (Schering).

ANTIPYRETIC, ANTI-RHEUMATIC, ANALGESIC, NERVINE. "The superior of all coal-tar antipyretics previously introduced." Dose, 7½ to 15 grains. Descriptive pamphlet (40 pages) supplied on request.

THIOL (Riedel).

A synthetically produced body, chemically and therapeutically identical with ICHTHYOL, and superior in being odorless and non-toxic. Supplied in powder and liquid form. Circular reprint of clinical reports sent on request.

LYSOL.

"THE IDEAL DISINFECTANT." The latest and most perfect of the cresol-derivative antiseptic and disinfectant agents. A 16-page monograph mailed on request.

Our motto "DEFINITE CHEMICAL PRODUCTS" has proved a happy hit, and it bids fair to become at once a catch phrase and the standard by which new remedies will be gauged.

Physicians are invited to write us whenever desirous of obtaining information regarding any new remedies. We will promptly answer all such inquiries.

A Sample Copy of "NOTES ON NEW REMEDIES" mailed on request.

LEHN & FINK,

IMPORTERS, WHOLESALE DRUGGISTS AND MANUFACTURING CHEMISTS,

ADDRESS: P. O. BOX 3114. **NEW YORK.** OFFICE: 128 WILLIAM STREET.

PEACOCK'S BROMIDES

(SYR: BROM: COMP: PEACOCK:)

Each fluid drachm represents 15 grains of the Combined C. P. Bromides of Potassium, Sodium, Calcium, Ammonium and Lithium.

USES: EPILEPSY, UTERINE CONGESTION, HEADACHE, AND ALL CONGESTIVE, CONVULSIVE AND REFLEX NEUROSES.

This preparation produces results, which can not be obtained from the use of commercial Bromide substitutes.

DOSE.—One to two FLUID drachms, in WATER, three or more times a day.

PEACOCK'S FUCUS MARINA

(ELIX: FUCI MAR: PEACOCK.)

From Sea Weed. **Uses: Malaria, Phthisis, Etc.**

An ALLY of quinine—quinine CHECKS the Malarial Chill, Fucus Marina ELIMINATES the Malarial CAUSE; and thus prevents the recurrence of the Chill *after* it has been *checked* by quinine.

An INVALUABLE REMEDY in the treatment of Phthisis—it arrests the decay of lung tissue, diminishes the fever, lessens the cough, abates the soreness in the lungs, improves the appetite, and impedes the progressive emaciation.

DOSE.—One Teaspoonful IN WATER, four times a day.

CHIONIA FROM CHIONANTHUS.

Uses: Biliousness, Jaundice, Dyspepsia, Constipation, and all Diseases Caused by Hepatic Torpor.

CHIONIA stimulates the Liver and restores it to a healthy condition, without debilitating the system by Catharsis; does not purge, per se, but under its use the Liver and Bowels gradually resume their normal functions.

DOSE.—One Fluid Drachm three times a day.

PEACOCK CHEMICAL CO., ST. LOUIS.

SUPERIOR TO THE MURIATE:

The Phenate of Cocaine

Not being absorbed into the organism when applied locally its anæsthetic effect is prolonged, and there is an absence of cocaine intoxication.

A NEW NON-TOXIC MEANS IN

PSORIASIS AND OTHER SKIN DISEASES.

GALLACETOPHENONE

FULL NOTES SENT FREE ON RECEIPT OF POSTAL CARD

THE PHENATE OF COCAINE.

Prof. v. Nussbaum.

"We know that phenic acid, from the point of view of its local action, presents certain analogies with cocaine; like the latter, it produces ischæmia and insensibility of the tissues. We would therefore expect that a combination of the two substances, under the form of phenate of cocaine, would have therapeutic properties, superior to those of the muriate of cocaine. This has been found to be the case by a Bavarian physician, DR. VON OEFELE, who has for some time past employed the phenate of cocaine exclusively in the place of the muriate."

He has found that the phenic salt exercises an analgesic action much more persistent than that of the muriate, while the chances of producing toxic effects are much less. Gluck was accustomed to add carbolic acid to his solutions of cocaine for the purpose of diminishing the chances of producing disagreeable results. These properties and advantages are explained by the fact that the phenic salt is almost entirely insoluble in water. Not being dissolved by the juices of the organism, the phenate of cocaine, employed as a local application, is absorbed but little or not at all, whence the absence of intoxication and the persistence of the analgesic action, which may last as long as thirty-six hours. Phenate of cocaine may be given internally as well as in hypodermic injection.—*La Semaine Med.*

GALLACETOPHENONE,

A NEW DERMATO-THERAPEUTIC AGENT.

BY HERMANN GOLDENBERG, M. D.

It is well known that pyrogallic acid is by no means a harmless drug. After its introduction into dermatological practice NEISSER lost a patient after one application. The patient died on the third day with symptoms of intoxication. VIDAL has likewise reported the death of a patient, eighteen years old, who had used a ten per cent. pyrogallic ointment for two weeks. This poisonous effect of pyrogallic acid is to be attributed to the great readiness with which it is oxidized in alkaline solutions (being so intensely reducing).

Gallacetophenone does not possess this quality and is absolutely harmless, as has been proven by experiments on animals.

It displays strong antiseptic qualities. A one per cent. solution added to chopped meat prevented its becoming putrid for twenty-one days, and destroyed the *Streptococcus aureus* within twenty-four hours.

Since the middle of October I have employed it, both in private and in dispensary practice, on at least thirty patients suffering from various skin diseases.

On account of its resemblance to pyrogallic acid, it seemed to be indicated in psoriasis. I have been so much more inclined to use it in that disease, since VON REKOWSKI, who tried it in a few cases only, maintains "that the effect of this new preparation (used as a ten per cent. ointment) is noticed within twelve hours."

Altogether, I have thus employed it in twelve cases of psoriasis—in all of them with good results. Within a few days the patches became paler and thinner, the desquamation ceased or became less, and involution took place in the centers. Usually after the lapse of from ten to twelve days only a slight hyperæmia was left. Within from two to three weeks the patches disappeared entirely without leaving any pigmentation.

A ten per cent. ointment did not produce any marked irritation or discolor the skin. It stains the clothes slightly yellowish, much less than pyrogallic acid or chrysarobin. In the case of psoriasis of the face and scalp it really acted like a specific. The eruption, which was quite profuse, disappeared within five days. A ten per cent. ointment was applied twice daily. There was no other treatment

Another patient with a universal psoriasis of sixteen years' standing, who applied to my department at Mount Sinai Dispensary for some other trouble, was induced to use a ten per cent. salve of gallacetophenone for the forehead and scalp, which were thickly covered with psoriatic patches. When he returned, two weeks later, there was nothing left but a pigmentation of the forehead, while the psoriasis of the body which had not been treated was *in statu quo ante.*

My friend, DR. G.T. ELLIOT, has, at my request, used gallacetophenone on a patient with psoriasis of eight years' standing, distributed over the trunk, knees, elbows, scalp, and face in patches of various sizes. The case had been under treatment the whole time and had proved exceedingly rebellious. Arsenic caused an increase of inflammatory symptoms. Pyrogallic acid had been used with but moderate success. Chysarobin did well, if used persistently. At the time (November 21st) when the use of a ten per cent. gallacetophenone ointment was begun, the patches were bright red, burning, and with abundant desquamation. A week later the patches were paler and breaking up into small papules. The centers had undergone involution and the desquamation was very little. Under the further use the improvement continued. DR. ELLIOT concludes his report with the following words: "From this slight experience, gallacetophenone appears to me to promise to be the most satisfactory local remedy for psoriasis and superior to all others. It produces no inflammatory reaction or pigmentation, but seems to influence immediately the lesions."

From my experience, I feel justified in recommending gallacetophenone as an excellent remedy for psoriasis, for it acts in some cases more promptly than chrysarobin—in all the cases which I have treated, as well if not better than the other remedies at our disposal. As it is harmless and does not discolor the skin or hair, I hope it will be found to be one of the best local remedies for psoriasis of the body, face, and scalp.

My results in a number of cases of eczema psoriti-forme and seborrhoicum have been so gratifying and encouraging that I should like to include these affections in its field of usefulness.—*N. Y. Med. Jour.*

JULIA W. CARPENTER, M. D., (*Cinn. Lancet Clinic*), also speaks of the rapid, almost specific, action of GALLACETOPHENONE in a very rebellious case of psoriasis.

FULL NOTES SENT ON REQUEST.

McKESSON & ROBBINS, NEW YORK.

DYSPEPSIA.

Deranged digestion is the most common of all human ailments. It is a truism that no organ of the body can preserve its normal integrity **when** its supplying nerve is disordered **by lowered tone.** But this fact is largely ignored in these modern pepsin days—the **cause** being lost sight of whilst trying to remedy the effect. It is well known that any unusual worry or anxiety will upset the digestion of **the neurotic** patient. Hence, in treating dyspepsia, particularly atonic dyspepsia, that form met with in persons of low vitality and poor appetite, there are **two distinct INDICATIONS.** One is to subserve the needs of general nutrition, the other is to subserve the needs of the nervous system. This can be done by giving the patient good nutritious food and a good nerve tonic. This explains why such remarkable results follow the daily use of **CELERINA** in all dyspeptic troubles.

Platt's Chlorides,

The True Disinfectant.

Twelve years of practical daily use, by tens of thousands of intelligent physicians, and by hundreds of thousands of careful housekeepers, has established beyond doubt the value, the usefulness and the superiority of Platt's Chlorides.

An odorless liquid, clean, stainless, powerful, efficient and economical, it is peculiarly adapted to all the sanitary needs of the sick-room, and the hygienic demands of the household.

Platt's Chlorides is sold in quart bottles only, and by nearly every apothecary in every city, town or village in the United States. Should there be any practising physician anywhere who may not, as yet, personally know its value, a sample, with descriptive circulars, etc., will be gladly furnished free.

Address, giving both Post and Express Offices,

HENRY B. PLATT, 36 Platt St., N. Y.

The Model Ledger enables a physician to make out his bills with great ease. Besides this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

GASTRIC DERANGEMENTS

HORSFORD'S ACID PHOSPHATE

Unlike all other forms of phosphorus in combination, such as dilute phosphoric acid, glacial phosphoric acid, neutral phosphate of lime, hypophosphites, etc., the phosphates in this product are in solution, and readily assimilated by the system, and it not only causes no trouble with the digestive organs, but promotes in a marked degree their healthful action.

In certain forms of dyspepsia it acts as a specific.

Dr. T. G. COMSTOCK, of the Good Samaritan Hospital, St. Louis, says: "For some years we have used it in a variety of derangements characterized by debility, as also in chronic gastric ailments. It is approved of, unanimously, by the medical staff of this Hospital."

Send for descriptive circular. Physicians who wish to test it will be furnished a bottle on application, without expense, except express charges.

Prepared under the direction of Prof. E. N. HORSFORD, by the

Rumford Chemical Works, Providence, R. I.

TYPHOID FEVER—ETIOLOGY, PATHOLOGY, DIFFERENTIAL DIAGNOSIS AND TREATMENT.

By W. R. BLAILOCK, M. D.,
M'GREGOR, TEXAS.

Short, concise papers on occasions of this kind are more appropriate and better received than long, statistical ones, but to write briefly and comprehensively where so much is involved would require more skill in writing than I possess. A short, crisp, full and comprehensive definition of a disease, affecting so many parts of the body and attended by such a multiplicity of symptoms as the one under consideration, from its inception to its close, is difficult to produce. Such a definition is desirable because under the head of Differential Diagnosis a continued fever believed by many to be a different, and distinct fever will be considered. In Pepper's "System of Medicine" typhoid fever is thus defined—"An endemic infectious fever, usually lasting between three and four weeks and associated with constant lesions of the solitary and agminate glands of the ileum, and with enlargement of the spleen and mesenteric glands. Its invasion is usually gradual and often insidious. Sometimes the only symptoms present in the beginning are a feeling of lassitude, some gastric derangement and a slight elevation of temperature; at others there are slight rigors or chilly sensations, headache, epistaxis, diarrhœa and pain in the abdomen. The principal symptoms of the fully-formed disease are a febrile movement possessing certain characters,—headache passing into delirium and stupor, diarrhœa associated with ochery-yellow stools, tympanitis, pain and gurgling in the right iliac-fossa, a red and furred tongue which later often becomes dry, brown and fissured; a frequent pulse; an eruption of rose-colored spots occurring about the seventh or eighth day, slightly elevated above the surface, disappearing under pressure and coming out in successive crops, each spot lasting about three days; prostration not marked in the beginning, but rapidly increasing and occasionally deafness, sweats and intestinal hæmorrhages."

When recovery takes place the convalescence is usually tedious and may sometimes be protracted by the occurrence of one or more relapses. Typhoid fever occurs in males and females with equal frequency, in infancy or old age, but is more common under the age of thirty years.

Recent arrivals in an infected locality are more apt to contract the disease than residents.

It is more prevalent during the latter part of summer and early autumn, though it may prevail at any season of the year.

After hot, dry summers and when the water used for drinking purposes gets low it is more apt to prevail. Often heavy rains following a drouth arrest the spread of the fever. Under ordinary circumstances the period of incubation is about two weeks, but in this there are exceptions, fever may begin in three or four days, or not until three or four weeks after exposure. Diarrhœa usually occurs early, the stools being ochery-yellow or dark, following the administration of a purgative or coming on of its own accord. Sometimes constipation persists throughout the disease even in cases that terminate in perforation. Pain in the abdomen usually accompanies diarrhœa.

The abdomen is often tympanitic with gurgling and tenderness in the right iliac fossa. Sir Wm. Jenner says, "Whether there is much distention of the bowel or

not, the convexity of the abdomen is always from side to side, not from above downward, tub-shaped not pot-bellied." The tongue is usually coated, with red edges, pointed, becoming dry, sometimes flaccid or uniformly red and glistening or glazed, or remaining moist throughout. Jenner says, "The small, dry tongue with red tip and edges, smooth furred of a pale brownish color and fissured, the surface seen between the fissures being of a deep red, may be considered differentially as diagnostic of typhoid fever. The tongue is often tremulous and protruded with some difficulty. A papular or pimply eruption consisting of little circular or lenticular spots of a bright-rose color that disappear under pressure, returning as soon as the pressure is removed, appear usually on the seventh or eighth day, but may be deferred until the twentieth day. These spots are sometimes absent in adults and often absent in children. Murchison found them present in 4,606 cases out of 5,988. They usually occur on the abdomen or chest, but they are frequently found on the back, sometimes on the hands and face. These spots frequently do not appear until after the application of a poultice. They come in successive crops each lasting about three days and the number present at one time, according to Watson, varies from one to sixty. No relation has been proved to exist between the copiousness of the eruption and the severity of the disease.

The hair usually falls out after an attack of typhoid fever.

Bronchitis is a common accompaniment. Headache is almost a constant symptom, usually referred to the forehead, often dull and not much complained of, but sometimes excruciating, simulating acute meningitis. Mental hebetude is usually present, but many cases have been reported ending in perforation and death where this condition was absent. Delirium varies with the severity of other symptoms, in the milder form consisting of only slight confusion of ideas easily dispelled by fixing the patient's attention. It may come on in three or four days, often not until the second week, sometimes as late as the fourth week.

In cases of long duration there is sometimes mental disturbance coming on when the fever subsides, amounting to mild insanity. The spleen is sometimes enlarged so that during the second week it may be detected by percussion but it is often difficult on account of tympanitis, to detect it by palpation. Intestinal hemorrhage may occur during the first week, but oftener from end of second week on. Prostration, approaching collapse, the pulse growing weak and thread-like, the surface bathed in a clammy sweat, the temperature rapidly falling indicate hemorrhage. After these symptoms a discharge of blood will likely occur in a few hours or two or three days. The temperature usually rises again after a hemorrhage has occurred.

Perforation is accompanied by nearly the same symptoms less the rapid fall of temperature and with the addition of sharp and severe pain in the abdomen and the occurrence of general peritonitis in a few days. The absence of liver dullness is considered diagnostic of perforation though it may be present after perforation; case of this kind was reported recently in the *N. Y. Med. Journal.*

Etiology: — Murchison says: "The poison of enteric (typhoid) fever is contained in the emanations from certain forms of putrefying organic matter. Pathogenic (typhoid) fever is often generated spontaneously by fecal fermentation. It is occasionally communicated by the sick to persons in health."

In 1880 Eberth discovered a bacillus which is now generally conceded by pathologists to be constantly present in the spleen and intestinal glands of typhoid cadavers, and that it stands in an etiological relation to this disease. Many experiments have been made with pure cultures of this bacillus, but as none of the lower animals have typhoid fever as it occurs in man, they have not been altogether satisfactory. Dr. Victor C. Vaughn has found that certain toxicogenic germs found in drinking water produce the same lesions in animals as the Eberth bacillus.

Dr. Sternburg in an address on medicine at Yale University, June 28, 1892, sums up the results of experiments with Eberth's bacillus: "It has been shown that this bacillus as obtained from the spleen of typhoid cadavers varies somewhat in different cases, that very similar bacilli may be obtained from water contaminated by sewage, etc., which differ from the typhoid bacillus in certain characters of growth, and yet resemble it so closely, that it is still uncertain whether they are to be considered distinct species or only varieties of

the typhoid bacillus; that the character which was at first supposed to distinguish the typhoid bacillus from all others, viz; its invisible growth upon potato has proved to be unreliable inasmuch as certain other bacteria have been shown to have a like invisible growth, and under certain circumstances the typhoid bacillus may form a visible growth upon potato."

Dr. J. Karlenski has recently published the results of two years' experiments with pure cultures of typhoid bacilli, typhoid dejecta and pieces of organs from typhoid cadavers, buried in earth that was humid, or approached natural conditions.

He ascertained that the longest time the bacilli remained alive in soil was three months. The life of the bacilli in typhoid dejections buried in soil was much shorter than in pure cultures under the same conditions. The deeper the bacili were buried and the less exposed to sunlight the longer the vitality.

He also found living typhoid bacilli at the end of three months in the organs of persons dead of typhoid fever where the conditions of inhumation were such as to exclude the specific organisms of putrefaction. Typhoid bacilli are widely distributed and do not always produce a specific effect, when introduced into the alimentary canal.

For the past three years I have made numbers of potato cultures from fecal matter passed by patients during the second and third weeks of fever.

At first the bacilli found in undoubted typhoid seemed to differ in size and motion from those derived from doubtful cases. More extended cultures embracing healthy fecal matter, that from privies, and from typhoid fever where hemorrhage from the bowel has occurred, have changed that belief.

It has been claimed that typhoid bacilli and the common colon bacilli act differently upon sterilized milk, one coagulating it, the other not.

I have found no difference both coagulating it in from sixteen to twenty hours, whereas milk sterilized at the same time and in the same way has remained fluid up to the present.

Morphologically bacilli from well defined typhoid cases do not differ from those derived from healthy fecal matter. The intimate relation between drinking water polluted by human excrement and typhoid fever the acknowledged abundance and distribution of the typhoid bacillus; the necessity for other secondary causes to determine infection, as "individual susceptibility," exposure to agencies that reduce the vital resisting force, virulence and quantity of bacilli, the state of the digestive functions emphasize the probability that the colon bacillus, and Eberth's bacillus are the same.

Pathology:—The liver, kidneys, spleen and many other organs or parts of the body, are more or less affected in typhoid fever but its constant and distinguishing lesion is an inflammation of the solitary and agminate glands of the ileum.

These glands are more numerous in the lower part of the ileum and it is here that the poison is usually most active, sometimes extending only a few inches up the gut. The ileo-cæcal valve forms the lower boundary of these glands while in the other direction they extend into the lower part of the jejunum. The glands are lymphoid nodules destitute of villi, surrounded by close rows of villi and simple follicles. They are situated on the opposite side of the bowel from the mesenteric attachment. The solitary glands may be affected and Peyer's or the agminate glands remain healthy, but this is not a frequent occurrence. The process begins as a catarrhal inflammation of the mucous-membrane, followed by changes in the lymphatic follicles. Lesions in the lymphatic follicles have been observed forty-seven hours after the beginning of the fever. The enlargement of the solitary and agminate follicles may be slow or rapid, slight or so pronounced as to fill up the cavity of the intestine. Delafield and Prudden in their Pathology, Anatomy and Histology give the following summary of the changes that take place in these glands:

"(1.) If the disease was mild and the enlargement of the follicles moderate, the enlargement gradually disappears and the follicles resume their normal appearance. (2.) In moderate enlargements the retrograde processes affect first the follicles and leave the septa between them still swollen and prominent. This gives to the surface a reticulated appearance. After a time, however, the entire patch becomes flattened and uniform. (3.) The solitary follicles or the separate follicles of a patch

soften, break down and their contents are discharged with some attendant hæmorrhage. This leaves a bluish-gray pigmentation in the situation of each follicle. (4.) In more severe types of the disease, the enlargement eof the follicles ends in ulceration. This takes place in two ways: (a) The enlarged follicles soften, break down and discharge into the intestines. In this way are formed small ulcers. These ulcers increase in size by the same softening process which gradually attacks their edges, and in this way ulcers of large size may be formed. The ulcers may extend outward only to the peritoneal coat, or they may involve the peritoneal coat also and perforate. (b) In the severest forms of the disease considerable portions of the enlarged patches slough, are detached, and leave large ulcers with thick, over-hanging edges. The slough may involve only the follicles or it may involve also the muscular and peritoneal coats. These ulcers also may afterwards increase in size and several of them may be joined together."

DIFFERENTIAL DIAGNOSIS.

A differential diagnosis to meet the requirements of this occasion calls for a description of a fever very common in Texas and that has been called "continued fever, slow fever, irritative fever, typho-malarial fever," etc.

During an intimate association of ten years with this fever and carefully noting it in its every detail, I have found the following prominent symptoms: Onset of fever usually insidious, frontal headache, sometimes no pain in head, tongue usually coated, with red edges, becoming pointed and dry as fever advances. Sometimes it is broad or natural in size, either pale or red, remaining moist throughout the disease. Sharp rise of temperature during the afternoon or evening with a fall during the latter part of night and early morning.

Profuse perspirations very common during latter part of night sometimes preceded by chilly sensations and rise of temperature. Epistaxis often occurs during first week, abdomen usually tympanitic and tender in right iliac fossa. Sometimes no tenderness nor tympany exists in this locality but on the left side on a level with and below the umbilicus a circumscribed area of tenderness and tympany exists. In these cases constipation is sometimes pronounced. Bowels often loose especially after first week or following the administration of a purgative. Dejecta often a dirty yellow or brown to red brown or black in color and very fetid.

Often a papular rose-colored eruption more or less abundant on the breast or abdomen often on the back, frequently not seen until after the application of a poultice. These spots have not been observed with the same frequency as we would expect in typhoid fever, but a diligent search will reveal their presence in many cases.

Hæmorrhage from the bowels occurs sometimes. Slight delirium sometimes, only during the night, coming on usually during the second week, from which patient can be easily aroused. Subsultus is often present, occasionally profound delirum comes on and the other symptoms characterizing the typhoid condition.

New-comers are more apt to contract the fever than those who are acclimated. It is more prevalant during the summer and autumn, especially when the water gets low and noticeably bad in wells. The cause of this fever seems to be impure water.

During the past ten years, in and surrounding the town where I reside, these fevers prevailed almost exclusively, where well-water had been used for drinking purposes. A few cases have occured where cistern water was used, but the faulty manner of collecting and preserving it gives ample explanation. During 1884 a well sunk the previous year upon the business street of the town, was much patronized on account of the purgative and other supposed medicinal properties of the water. Many who used this water had the fever. A chemical examination revealed the presence of albuminoid ammonia.

During the early days of McGregor and up to a year ago many of her citizens used well-water, others brought water from portable tanks that were supplied with water from springs far removed from fecal contamination. These wells are sunk in porus shelly and fissured rock to a depth of from fifteen to thirty feet where a compact blue limestone is encountered. This blue limestone is the lower limit of the surface, water bearing, rock and is so compact that water does not penetrate it.

Of those who used well-water many contracted fever with the symptoms above

given, while of those who brought water from the tanks not a single case came under my observation.

One year ago water works were put in, the supply being from artesian wells 1,000 feet deep and cased so as to exclude all surface water. Up to the present not a single case of fever has been developed that could be traced to this water. On the other hand there are some families who from choice, or on account of living in outside districts of the town still use surface well-water. Among these the fever has been very common.

In August, 1891, a fire occurred in a stone building that contained 100 tons of baled hay. Fifty gallons of water per minute was thrown into this building for a period of twenty-four hours, and not a drop ran off on the surface.

Two days afterward a couple of wells 700 yards east, one 200 yards south and two west, 300 and 400 yards respectively, were found so strongly impregnated with the taste of burnt hay that the water for several weeks was totally unfit for use.

The description of the surface wells in McGregor is a description of the surface wells throughout this country where numbers of cases of fever have occurred.

I would give some illustrative cases, but this paper is already too long. Before proceeding further I wish to state distinctly that I have seen fevers continue from three to fourteen days due to malaria, or errors of diet, etc., but these lack the distinctive abdominal lesions above given. The fevers I have observed never terminate under eighteen to twenty-one days, and often longer. Now for the differentiation: Typhoid fever is nearly always derived from impure water, especially that contaminated by human dejecta. The same is true of "continued fever." Typhoid fever is marked in the majority of cases by certain abdominal peculiarities—, tympanitis and tenderness in right iliac fossa, "tub-shaped," loose bowels occurring after the administration of a purge or coming on of its own accord, sometimes constipation throughout the disease. "Continued fever;" acts the same way. In typhoid fever hæmorrhages from the bowels sometimes occur. The same may be said of "continued fever."

A papular eruption occurs in typhoid fever in a certain proportion of cases. It is sometimes present in "continued fever." Other causes than the presence of the typhoid bacillus are necessary to determine infection, therefore every one who is exposed does not contract the disease.

"Slow fever" requires the same secondary causes, therefore only one or two cases may occur in a family.

Typhoid fever sometimes drifts into the typhoid condition, which is thus graphically described by Tweedie: "It is announced by the decline of the previous more acute symptoms, by the pulse becoming more rapid and soft; the tongue dry, brown and tremulous and protruded with difficulty; by the incrustation of the teeth with sordes; by the increasing intellectual disorder indicated by the constant low muttering delirium and the greater insensibility and deafness; and by the condition of the muscular system which is evinced by muscular tremor and subsultus tendinum and in some cases by irregularity or intermission of the pulse; by the patient lying sunk on his back, or sliding to the foot of the bed, the muscles being unable to support the body even in the horizontal posture." "Continued fever" may drift into the typhoid condition with all of its attendant symptoms.

I think it is unnecessary to pursue this comparison any further, "things equal to the same thing are equal to each other," therefore, "continued fever" as it occurs in Texas is typhoid fever. It is there that in a great many instances it is very mild, much more so than we have been taught to expect in typhoid fever, but is not the abundance of pure air and the lack of concentration or virulence of the poison sufficient to account for it!

Until the pathology of "continued fever" is shown to be different from that of typhoid fever, or in fact until its advocates advance some pathology for it, I think it would be well to call it typhoid fever, or better, enteric fever, which would be a better name for both.

TREATMENT

The treatment of typhoid fever requires more watchfulness and diligence on the part of the physician and a stricter compliance with instructions on the part of the patient and nurse, than almost any other disease.

Nothing is more important than a definite understanding with both patient and attendants early in this disease.

To get the best results the physician's instructions should be faithfully carried out.

When a diagnosis of typhoid fever is made the patient should be put to bed and required to remain there until he is clear of fever during the whole day.

Strict cleanliness and thorough ventilation of the sick chamber should be insisted upon. This will necessitate frequent changes and airing of bed linen.

The next and one of the most important things to be done is to regulate the diet, or rather prescribe a diet. Only liquid food should be allowed under any circumstances. Sweet milk mixed with lime water to prevent coagulation, chicken water, beef essence, beef tea or a soft boiled egg, are often well tolerated, and serve the purpose admirably well, but I think nothing is so good and generally acceptable to fever patients as fresh cold buttermilk. It is impossible to prescribe the exact amount of milk that should be given; this must be determined in each individual case. Some patients will take from four to six glasses of milk during twenty-four hours while others are unable to take more than one or two without discomfort.

The alvine discharges indicate very clearly if too much is taken by containing undigested lumps.

In the application of medicine we should ever bear in mind that we are dealing with a self limited fever; one that under the most favorable conditions will continue from eighteen to twenty-one days.

We should also remember that it is not out of the natural order for the temperature to rise during the afternoon and evening and that unless it reaches 103° no active measures should be resorted to, to lower it.

Another point worthy to be remembered is that antipyretics administered during the afternoon and early evening may not have the same effect as when given during the latter part of the evening or early morning. Doses sufficient to make only a slight impression upon the fever when it is rising being sufficient, to often, produce perspiration and prostration if given near the time when the fever naturally, starts down.

After feeding, the regulation of temperature is next in importance. Antipyrine, Acetenalid, Phenacetin, Antikamnia and other similar preparations often do good service in this direction, but they should be carefully watched lest the depression produced counterbalance the good. In many cases cold water is all that is needed to regulate the temperature. Sponging the body with cold water, using the wet pack, putting patient in a cold bath or a graduated bath, are perfectly safe. For a bath nothing answers the purpose better than an ordinary cot, with a piece of rubber cloth spread over it. The patient wrapped in sheet, placed on this cot and water poured on until the temperature is sufficiently reduced.

After reducing the temperature with water, quinine in daily doses ranging from twenty to forty grains is often sufficient to keep the temperature within the normal bounds.

Quinine cannot be given indiscriminately in this fever. Some cases will not tolerate it, and if its use is persisted in will produce most disastrous effects. I have found where patients tolerate quinine it is best given during the morning hours, the daily amount being given in three or four doses.

Turpentine stupes over the abdomen when there is pain and tympanitis, are very comfortable to the patient and useful. Mineral acids, though very much used a few years ago, are rarely prescribed now, as they are found to do very little good except as a solvent for quinine.

Some recent discoveries, however, in regard to the gastric juice in febrile conditions, will justify the use of one of them. Gluzinski has found in a patient whose temperature was not above 102°, total absence of hydrochloric acid and not until the temperature reached the normal was there a trace of this constituent of the gastric juice.

There is always a diminution and often total suppression of hydrochloric acid in the gastric juice in febrile conditions. It is further asserted that the dyspeptic condition in fevers is due to the absence of this acid. This suggests the propriety of administering it combined with milk, as has been done in summer complaint.

Whenever the patient begins to show weakness whiskey or brandy should be given judiciously every 3 or 4 hours.

I think the advice given by many authors to wait until the two sounds of the heart can't be distinguished from each other before exhibiting stimulants, is erroneous.

This condition of weakness may be avoided by the timely administration of whiskey.

It is important to regulate the bowels; if they do not act give a mild purge; if this acts too freely use tr. opii, or tr. opii and bismuth. Often twenty or thirty drops of tr. opii given per rectum will control the bowel much better than if given per mouth.

Sleep is a very important factor in the treatment of typhoid fever. It has been said if a typhoid fever patient spends three successive nights without sleep, recovery is extremely doubtful. Chloral and pot. bromide are sometimes beneficial in the way of securing sleep, but I have found them rather weakening and unsatisfactory in many cases.

Tr. opium or sulph. morphia I think far preferable.

The specific treatment of typhoid fever has never given general satisfaction. Dr. Gustavius Eliot, of New Haven, Conn., in a recent article published in the *New York Medical Journal*, extols the German calomel treatment followed by tr. iodine and carbolic acid, as suggested by Bartholow. My experience with calomel has been very unsatisfactory. I have observed that in patients who take very much calomel during the early stage of fever, precisely the time it is recommended to be taken, hæmorrhages from the bowel are more apt to occur.

I have just dismissed two patients who took. of their own accord, large doses of calomel. One had rather an alarming hæmorrhage from the bowel followed by prostration and a tedious recovery; the other had an alarming hæmorrhage followed by death two days afterward.

Tincture iodine and carbolic acid, listerine, zymocide and other drugs of the same class may be useful in correcting the fetor of the discharges, and thereby lessening the intensity of the inflammation.

The internal administration of turpentine when the tongue is tender, is often followed by the most gratifying effects.

When the symptoms indicating hæmorrhage occur, ergotine hypodermically, and tr. opium administered by mouth, pushed to the limits of safety, are most useful. The propriety of applying cold to the abdomen, on account of the prostration and lowered temperature is extremely doubtful.

Perforation should not deter the physician from further efforts to save his patient because cases of recovery have been recorded by persons whose skill as diagnosticians can not be questioned. Here opium is the sheet anchor, because if sufficiently pushed it will keep the diseased bowel as effectually immobile as if it were placed in a splint.

Laparotomy has its advocates and no doubt lives may be saved by it, especially since suturing the bowel has reached such a degree of perfection that sections of it may be taken out.

This paper is not intended to be a full exposition of the symptoms, pathological changes, differential diagnosis, and treatment of this fever, but an effort has been made to present as briefly as is consistent with clearness, the more salient features of each.

A chapter on propylaxis might be written, but as it does not come within the scope of this paper and as it is already too long, a repetition and partial endorsement of the language of some one, I cannot now recall whom, will end this paper:

"Typhoid fever should be considered a disgrace to our modern civilization."

PARAPLEGIA OF SYPHILITIC ORIGIN.

Dr. Boulloch gives statistics to show that in sixty-two per cent. of cases the paraplegia shows itself during the first four years following the chancre. In eight instances it occurred in the first year. Retarded myelitis, that is coming on long after the chancre, either in the midst of tertiary accidents, or after a long period of inactivity, is of very rare occurrence. Figures show that medullary affections seem to burst forth twice as frequently in those who have had no mercurial treatment or only an insufficient treatment, as in patients who have been well cared for. Chronic myelitis is rarely fatal, but is also rarely cured. It appears as though paraplegias accompanied by severe pains are benefited more by mercury than the other, perhaps because of the existence of a gummous or sclero-gummous meningitis. Acute paraplegias, of precocious nature and rapid march, do not get well. Improvement is frequent in the tardy forms.—*Journal de Médecine.*

WOUNDS OF THE BRAIN AND THEIR RESULTS.

By FRANK P. NORBURY, M. D.,
JACKSONVILLE, ILL.

Wounds of the brain are worthy of our greatest consideration.—The diagnosis of the extent and location is difficult when the wound is without the motor areas. Extra-cranial symptoms do not indicate the extent of brain injury. It is often impossible to differentiate the form of brain wound.

Clinically wounds of the brain may be classed as follows: *contused*, *lacerated*, *penetrating* and *complicated*.

Contused wounds may be followed by shock only, and the symptoms of concussion are then pronounced. The severity of a contused wound is measured by results, if destruction of brain substance (red softening) follows, nutritive interference has ensued. Such changes are usually confined to cortex, but interior areas and nuclei of brain may be bruised by severe forces.

Secondary consequences of contused wounds are manifested in insanity and other neuroses. Insanity may immediately follow concussion or, at a period remote, mental changes, progressive and chronic, essentially degenerative, may develop. Clinical study of 2,600 cases seen by me shows traumatism so be a factor in the causation of insanity of greater import than that usually ascribed to it. The forms of traumatic insanity are illustrated in the three following cases, viz: Case I. S. S., age 64, farmer; insane two months; cause concussion of the brain; mental derangement immediately followed brain injury; hallucinations of sight for a time; delusions of persecution; carried money on his person to prevent its confiscation. No motor disturbance; slight anæsthesia right side, impaired hearing. Improved rapidly under treatment, made good recovery. Case II. G. E., age 18; laborer; insane one year. Cause a blow on the head. Incoherence followed the regaining of consciousness after the injury. Neurasthenia rapidly developed. He was treated for typhoid fever; the mental symptoms —hallucinations and delusions of persecution—were present from the beginning of the neurasthenia. When admitted was more or less somnolent, stupid, incoherent and very feeble. Four months elapsed before evidence of mental improvement was noticed. Gradually improved and recovered after seven months' stay in the hospital. Case III. J. W. Z., age 36; carpenter: Insane three weeks on admission. Cause unknown. Four years before had fallen from a scaffold striking on his head, causing depressed fracture left parietal bone. Nothing was done surgically: One year after injury a change in disposition was noticed and gradually he was turned against home and friends. He left home and soon after other changes were noticed. Intense headaches, insomnia, etc., developed and finally delusions of persecution and some hallucination. He gradually lost his hearing. When admitted showed unmistakable evidence of organic disease of the brain. Motor symptoms marked also sensory changes. The disease was so far advanced as to make prognosis as regards life very unfavorable: he died within a year of organic disease of the brain—*pseudo-paresis*.

Lacerated wounds are associated with contused wounds and always when concussion exists. Hemorrhages are frequent in lacerated wounds, the clots cause paralysis: hemiplegia when whole motor area is involved—monoplegia when one single locality, as in motor aphasia when Broca's convolution is affected. Idiocy is the prominent result of lacerated wounds of the brain, fully one third of all idiocy is due to traumatism. The meningeal hemorrhage resulting during parturition from protracted pressure or instrumental interference. is responsible for nutritive interferences to the brain, atrophy results and may be accompanied by convulsions, spastic contractions, athetosis, etc. An examination of the brains of idiots or imbeciles whose mental derangement is due to traumatic brain lesions, shows in most all cases conclusive evidences that atrophy, sclerosis, etc., were due to nutritive changes, induced by the brain injury.

Porencephalus is undoubtedly due to traumatism occurring during parturition or to injuries occurring later during infancy. Wounds of the brain during infancy are of more serious import than is usually supposed; a statistical study of the results

would be a sad revelation to careless parents. Inflammatory changes are common in infancy and the result is atrophy and sclerosis with attending mental, motor and sensory changes.

Penetrating wounds of the brain are of serious nature; the degree depending on the location and on the substance penetrating. Antiseptic treatment of such wounds has done much to save life. Gunshot wounds of brain are most fatal, because of great destruction to brain substance.

Complicated wounds of brain are the most common. They include all the foreign classes and in addition have fracture of the skull associated, hence the term complicated. Indications of treatment are to relieve hemorrhage, pressure symptoms, and make wound aseptic. Base may be fractured; if so have sense interval, and on this base diagnosis.

Results of complicated wounds may be all those given in other classes and in addition suppuration, meningitis, brain abscess, epilepsy, aphasia, paralysis and general disturbances of sensation; antiseptic precautions lessen liability to suppurative meningitis. Brain abscess never occurs unless there is solution of the continuity of the surface. Every traumatic abscess is preceded by a wound which communicates with the surface in some way.

Traumatic epilepsy has some focal point of irritation due to pressure or nutritive interferance with cortical areas. It may be relieved by relief of pressure, either by elevation of depressed bone or by removal of clots of blood on the surface of the brain. Relief must be given early if good is to come from it. Delayed operation is never productive of permanent relief. Early operation is advised. In children we must operate on first appearance of convulsions, ere sclerosis is too far advanced.

EPILEPSY.

In a severe case, after failure of other remedies, Dr. J. A. Proctor, of Union City, Ind., resorted to the following combination (*Med. Bull.*) Under its influence attacks ceased and have not recurred more for than two years:

℞ Sodii boratis.....
Ex. spigeliæ fl.....
Tinct. calumbæ.....
Ex. stargrass fl.....
Tinct. sanguinariæ ....āā..ʒ ij.
Ex. pulsatillæ fl.....ʒ j.
Aquæ, q. s. ad .....Oj.
M. Sig.—Teaspoonful three times a day.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Meeting of October 6th, 1892.

The President, Dr. W. H. H. Githens, in the chair.

Dr. William J. Taylor related a case of "Twin Pregnancy Complicated by a large Myoma in the Right Broad Ligament—Abdominal Section and Removal of Three Tumors—Abortion—Recovery."

Two years ago he had exhibited to this society three tumors which he had removed by abdominal section—a large myoma from the broad ligament, and two smaller subperitoneal ones from the posterior and upper surface of the uterus. The case had, at that time, elicited much adverse criticism and he thought the subsequent history of the patient might prove of interest. The patient had always been healthy; had worked on a farm in Ireland, often doing the work of a man. When first seen by Dr. Taylor, there had been absence of menstruation for five months. There was constant nausea and vomiting, the tongue was dry and somewhat coated. The pulse was rapid, 120 per minute, and very weak. There was diarrhœa which had lasted for several days. The urine contained albumen. She complained of great pain in the abdomen, especially on the right side. The bladder was very irritable. There had been no bleeding or discharge from the uterus. The breasts showed well marked signs of pregnancy and contained milk. The abdomen was enlarged and in the right iliac region was a mass about the size of a small cocoanut, which was hard, fixed and painful. This tumor had been growing very rapidly and was becoming more painful every day.

The diagnosis was obscure and Dr. Taylor was in doubt whether it was an extra-uterine pregnancy or a rapid growing myoma. At the section, two large tumors presented which were joined below but were separate above. The tumor to the left was the pregnant uterus while to the right was the new growth. The great mass of the tumor was between the layers of the broad ligament—a true intra-ligamentous myoma. This was enucleated from its

capsule and removed. There were two sub-peritoneal myomata, about an inch and half in diameter, which were also removed, one from the upper and one from the posterior surface of the uterus. Several small myomata, dotted here and there over the surface of the uterus, were allowed to remain. The patient reacted well from the operation, which was one of great difficulty and consumed much time, especially in the arrest of hemorrhage.

She did well until the sixth day when she began to show signs of aborting and suffered great pain in the region of the wound especially. For this reason and in the fear that persistent aud active uterine contraction might do serious damage, and as the os uteri was widely dilated and a foot of a fetus presented, active interference was decided upon. A fetus of a little over four months' development, along with its membranes and placenta, was removed and it was thought that the uterus had been emptied—the manipulation being of necessity very limited for fear of doing damage to the wound. On the eighth day, she was delivered spontaneously of a second fetus, which was alive and lived for an hour. Up to this, her attendents had no suspicion of a twin pregnancy. Except for an attack of phlegmasia dolens, her recovery was satisfactory. Some time after leaving the hospital she suffered from persistent diarrhœa which exhausted her greatly and refused to yield to treatment, finally ceaseing spontaneously.

Fourteen months after the operation she was delivered of a fine boy, now alive. Dr. Taylor did not attend her in the labor but learned from her that she was in labor about sixteen hours and that she had intense pain. The perineum was badly lacerated. Again she became pregnant and was delivered of a healthy girl. She now comes to Dr. Taylor suffering with a torn cervix and badly torn perineum with an almost complete prolapse of the uterus. The abdominal scar is in perfect condition and there is no evidence of trouble at that point.

DISCUSSION.

Dr. B. C. Hirst said that he considered the case remarkable for two reasons. The hemorrhage was extremely alarming from its profuseness and from its situation. In the second place he thought the abortion due to the death of the fetus and not to the operation. If it had been due to the operation, it would have occurred sooner. He was glad to see the course that was pursued and that the procedure was justified by the subsequent history of the case.

Dr. M. Price made a few remarks on the subject of "Emergency Cases in Abdominal Surgery" and presented the following cases:

1. RETENTION OF URINE.

The patient was seventy-nine years old and suffering from retention of urine due to an enlarged prostate. He had been unable to pass urine freely for a long time and for several months it had been constantly dribbling. It was impossible to pass a catheter. The Hunter Maguire operation of supra-pubic cystotomy was performed, the bladder freely washed out and stitched to the abdominal wall, a rubber drain having been introduced with a gauze drain above and below it. Patient passed urine freely through the rubber drain; all drainage discontinued after the sixth day. Hunter Maguire's aluminium plug was used to keep the opening into the bladder patulous. The prostate was as large as a double fist. Patient recovered.

2. TUMOR OF RIGHT TUBE.

Patient twenty-eight years old, suffering from a small tumor of the right tube, the left being densely adherent and cirrhotic, not larger than a lima bean. She had been an invalid for six years; one year and a half under the rest treatment; electricity by a celebrated gynecologist. Patient made an excellent recovery.

3. REMOVAL OF OLD PUS-TUBE.

The patient, a colored woman, twenty-six years old, had contracted gonorrhœa from her husband at the time of marriage, but had recovered so far as vaginal discharge is concerned. She had been unable to work for a long time, owing to frequent attacks of pelvic trouble, and was a confirmed invalid. The tumor extended above the umbilicus, rather to the left of the median line, and contained pus, blood and a watery fluid. There had unquestionably been a rupture of an old pus-tube and a violent general peritonitis. Two-thirds of the pus sac was enucleated and

tied off. It was impossible to remove the other third as the adhesions were stronger than the sac itself, and it was adherent directly over the iliac vessels. Thorough irrigation and gauze and glass drainage; recovery.

4. ECTOPIC PREGNANCY.

Patient thirty-six years old, suffering from terrific hemorrhage from a ruptured ectopic pregnancy. She was pulseless at the time Dr. Price saw her, ghastly pale, respiration sighing, sick stomach, with a feeling of something in the bowel, constant diarrhœa, distended abdomen, normal temperature. As soon as the abdomen was opened, blood poured from the incision. The ruptured tube was delivered and tied off. At least a pint of clot was removed from the pelvis; quantities of liquid blood also discharged. Thorough irrigation and glass drainage for six days; free purging and liquid diet after the second day. The patient rallied from her hemorrhage very slowly but made a perfect recovery.

5. RUPTURED DERMOID OF THE RIGHT SIDE.

Patient had been suffering from the tumor for five years and had had repeated attacks of peritonitis. During the very hot weather the tumor ruptured and from that time on she suffered from peritonitis; the bowels at the time of operation, September 3rd, being covered with inflammatory lymph and looking very much as if parboiled. A number of pitchers of water were used for irrigation and a glass drainage tube inserted. She made an uninterrupted recovery.

The water used in these cases was plain boiled water, cooled down by other not boiled and seemed to get rid of microbes so far as could be judged by the effect on the patients and their recovery.

6. PYOSALPINX AND OVARIAN ABSCESS.

A pyosalpinx and ovarian abscess of the right side, resulting from gonorrhœal infection at the time of marriage, had been removed from this patient. At the time of operation the left side appeared healthy, but the principal reason for leaving it was the already almost hopeless condition of the patient. Drainage was continued for four days and was followed by a fistulous track through which the patient menstruated regularly and which persisted for seven months in spite of efforts to close it. At the end of seven months it ceased discharging and her physician found her to be pregnant. Owing to indiscretions in lifting, she miscarried but recovered nicely from this and in the latter part of 1891 again became pregnant and was delivered of a healthy girl.

Dr. Price stated that this was the third case of undoubted gonorrhœal tubal troubles where one side was left. One had to be operated on the second time. This one now reported and the third remained perfectly well.

7. TUMOR OF ABDOMEN COMPLICATING PREGNANCY.

The patient was thirty-one years old; always healthy. Four months after marriage she became pregnant but her abdomen enlarged much more quickly than a pregnancy of one or two months would account for. She was suffering from severe peritoneal pain and constantly increasing distension, with a large tumor on the right side extending up to the kidney. Her condition demanded immediate relief and a large fibroid was removed along with the pregnant uterus containing a dead fetus of about three months.

The specimen was of great interest and from the large growth, sarcoma rather than a pure fibroid was suspected. The walls of the uterus were thickened in all directions and from their unyielding character had caused the death of the fetus at this early date. Patient recovered without any complication.

8. TWO CASES OF APPENDICITIS—OPERATION.

The first patient was suffering with a well marked tumor in the right iliac fossa of ten days' formation. First attack of appendicitis. Persistent constipation for five days. Six to eight ounces of pus were discharged. Thorough irrigation; gauze packing. Recovery without any trouble.

The second patient had been suffering from mild attacks for fifteen years; never so severe as to completely incapacitate him for work. The last attack began with severe and agonizing pain in the region of the appendix. Hypodermic injections of morphia with free purgation were used for

a few days with seeming relief. His symptoms increased in severity and Dr. Price was called in consultation. At the operation, the intestines were found matted together and were separated with great difficulty. Six to eight ounces of black, offensive pus were evacuated; thorough irrigation of the peritoneum and abscess cavity, with gauze packing and a rubber drainage tube of large calibre in the abscess cavity and a gauze drain also of the peritoneal cavity. Complete recovery.

9. STRANGULATED DIRECT INGUINAL HERNIA.

The patient had been vomiting questionable matter for four days. The bowel was dark but not gangrenous, so it was freed and examined for bands of adhesions and washed with boiled water that had been cooled down to a proper temperature. Recovery was rapid.

Dr. Price also presented a paper on Hard Tumors of the Uterus. He said that many of these tumors are of varied and entirely different pathological appearance and would seem to have originated from different causes or conditions in fibroid changes. These tumors are of low vitality and prone to develop rapidly into malignant forms of disease.

Dr. Price stated that he had examined over one hundred of these hard tumors to ascertain the manner of their growth and development. In the true fibroma there is but a trace of muscular fibre and but little connective tissue and most of that in its capsule. The vascular supply is almost entirely in the capsule, with small vessels running into the tumor. As the tumor advances in size the vascularity of the capsule increases.

In the myomatous tumors the bloodvessels are very numerous throughout the tumor, tortuous, and of large caliber. The muscular element can be demonstrated without difficulty and the growth of the tumor is much more rapid, in comparison with the hard nodular variety, and is much more apt to be confounded with pregnancy. The myomatous variety is much more apt to be diffused, or one face of the uterus covered with the growth, with the uterine canal passing half round the tumor. Dr. Price had never seen a tumor that occupied the entire walls of the uterus. The nodular variety has its beginning, in most instances, in the muscular structure of the uterus and may travel in its growth either to the uterine cavity or in the direction of the peritoneal cavity: the latter being the most common, as that is the direction of least resistance. In either case they may become pedunculated. It is rare to see a true hard fibroid single: most of them are multiple, with one large nodule surrounded by a number of smaller ones.

DISCUSSION.

DR. WILLIAM J. TAYLOR asked if it would not have been possible to have removed a portion of the prostate, in the case of enlarged prostate, so as to give a passage through the urethra.

DR. PRICE replied that he could have removed the prostate, but that it was situated very deeply and he thought the patient could do better as he is.

DR. B. C. HIRST reported the following case of "A large Collection of Pus Between the Layers of the Broad Ligament Complicating Pregnancy." The patient was a middle aged woman in the fifth month of pregnancy, a number of years having elapsed since the last child. She had been confined to bed for about eleven weeks. A large tumor could be made out alongside the uterus and at the section a cystic tumor was found between the layers of the right broad ligament, containing about two quarts of pus, which was incised and the pus evacuated. The sac was sewed to the abdominal wall. The woman recovered. Dr. Hirst thought that it was likely that this was a suppurating intraligamentary cyst. He thought it remarkable as complicating pregnancy, and as an unusual termination of a monilocular broad ligament cyst, which usually contains a clear limpid fluid; not at all prone to septic changes.

DISCUSSION.

DR. CHARLES P. NOBLE said that this question of abscess under the peritoneum is an interesting one, but he thought that, unless Dr. Hirst is more definite in regard to the real nature of this abscess, it has not very much bearing on the question whether you have broad ligament abscesses or not. He thought the case did not come under the head of broad ligament abscess, but of suppurating broad ligament tumor. He had seen a number of broad

ligament abscesses but they had all been puerperal.

Dr. M. Price said, we have never denied that there may be abscess anywhere, in the broad ligament or between the folds of the peritoneum in any portion of the abdomen, but what we do deny is the frequency of these things and the ability of the operator, with his finger in the vagina, to say whether the mass is inside or outside the peritoneum. These collections can be drained outside of the peritoneum but what have you done? You have attempted to drain an abscess, with probably a necrotic tube, diseased appendix or some other condition inside, which will keep up the trouble for a long time, probably with a fistulous tract for months. The only proper treatment is to go into the peritoneal cavity and remove the diseased condition that has produced this abscess; let it be exterior or interior to the peritoneum. Eighty or ninety per cent. of all pelvic troubles have been in the start intraperitoneal and have been taken care of by nature and at the time of operation are found extra-peritoneal, having been shut off from the general peritoneal cavity by inflammatory adhesions. There are cases of puerpural trouble where, from laceration of the cervix, an abscess has formed in the cellular structures around the cervix, but these abscesses are exceeding rare, so rare that a man scarcely sees one of them, while the other condition is common.

Dr. Joseph Price said that this paper opens up some points of dispute in regard to pathology, natural history and surgery and he should like to make a few remarks in regard to his own personal experience. He was not willing to accept the literature on this subject of intra-ligamentary cyst. The reported cases are all on record in doubt, as the one this evening. The reporter is still in doubt as to the character of the tumor—he thinks it contained pus. We know that parovarian cysts contain a clear fluid which is the least likely to change. It is the purest form of liquid which we remove from the pelvis. He had never known a parovarian cyst to suppurate. It was his impression that in the case reported, the enucleation would have been easy. He was not willing to say that the patient was well. The time will probably come when it will be necessary to repeat the procedure and remove the tumor. He had yet the first case of intra-ligamentary or broad ligament cyst to see.

He had removed many ovarian abscessess and pus accumulations and after removing them, he could hold up the remains of the broad ligament to the light and demonstrate clearly that there is not the semblance of suppuration in the cellular tissue at that point. He knew that abscesses occur at all points where we find cellular tissue, but, in the vast majority of cases, pelvic abscesses are due to traumatism or to extension. They occur in the cellular tissue precisely as in the ovary. Ovarian abscesses in 99 out of 100 cases follow a suppurating tube. There is an attachment of the pavilion-end of the tube to the ovary through which infection takes place and abscess develops. It is folly to take the position that these things are primary and that they do occur in the broad ligament so frequently without cause.

Dr. Barton C. Hirst in closing the discussion, remarked that the usual contents of broad ligament cysts being so pure, he had been surprised to find an abscess in that situation.

Dr. J. M. Baldy reported a case of chronic abscess due to appendicitis. The patient had been sent to him for an opinion in regard to a rapidly growing tumor that had first been noticed two years previously as a small protrusion from the external inguinal ring on the right side. A truss had been applied under the impression that it was a hernia. When seen by Dr. Baldy the growth was the size of a fetal head and had much the appearance of a sarcoma. At the section, a quart or more of pus escaped and the abscess cavity was found situated between the skin and muscles, with an opening at its lower end which communicated with the head of the cæcum, dipping down behind the muscles at their attachment to the iliac bone. The cavity was carefully irrigated and two drainage tubes were placed—one extending behind the muscles into the abdominal cavity, the other in that portion of the cyst between the muscles and the skin. Recovery was slow but good. On careful inquiry after recovery, the following history was elicited. She had had some three or four years previously an attack of inflammation in the region of the tumor, which lasted for several weeks and gradually left her. She had thought nothing

more of it and had not connected the so-called hernia with it. The original attack was undoubtedly an appendicitis and the pus cavity had existed in a quiescent state for years.

Dr. Baldy also reported a case of malignant peritoneal cyst and stated that he had called the tumor by this name as he did not know how else to call it, never before having seen or heard of such a condition. Before operation he had considered the tumor a par-ovarian cyst, free from adhesions. The uterus and ovaries could be palpated and were free from disease. At the operation the cyst was found densely adherent to the abdominal walls and the point of division was found with difficulty—the sensation imparted being that of passing through connective tissue. In attempting to break through the adhesions at the upper margin of the tumor, the finger slipped and entered the cyst itself, emptying it of a gallon or more of dark, flaky fluid. The interior of the cyst cavity was lined with a soft, velvety, membrane, studded all over with either tubercular or malignant nodules. The posterior wall seemed made up of coils of intestine, covered with this velvety membrane. The ovaries had both undergone cystic degeneration. To the side of both ovaries, and apparently growing from them, were papillomatous masses. The tubes were shortened and thickened, the fimbriated ends both perfect, but short and stumpy; and the uterus quite large and heavy. The whole pelvic cavity formed part of the cyst cavity, the bladder bulging into it in front.

A drainage tube was placed in each flank, between the cyst wall and the abdominal wall; and a third one inside the cyst, to the bottom of the pelvis. The patient's recovery was slow but satisfactory. She still has a sinus into the pelvis, which dicharges a variable amount of thin fluid from time to time.

Dr. Baldy stated that the only explanation he had been able to make of the case was, that there was a congenital anomalous distribution of the peritoneum, which, later is life, took on malignant changes.

DISCUSSION.

Dr. Joseph Price said that this was not the proper society to discuss the subject of appendicitis, as the men are not here who cure these by palliative measures, opium and rest. These men tell us of the cases that they have treated in this way, following the opium by a little calomel or a little rochelle salts and the patients have done fairly well. On inquiry we learn that other eases, treated by them in the same way, have not done so well, and that after continuing the treatment for several days, they have finally called in a surgeon when the patient was in a dying condition. These patients often carry these abscesses for several years, travelling from one part of the country to another in search of relief, having as many as twenty-four attacks, and the case goes on record by twelve physicians, each curing two attacks. He has presented specimens here, removed in the fourth, fifth or sixth atteck, that some one else was reporting as a recovery under palliative treatment. Not a week passed this summer without a case of appendicitis. All of them had been neglected, all had had a number of attacks treated by so-called medicinal or palliative treatment without the slightest relief.

Dr. George E. Shoemaker said that, while it is difficult to criticise a case that one has not seen, it seems reasonable to suppose that the so-called peritoneal cyst reported by Dr. Baldy, was a case of tuberculosis of the peritoneum which had caused adhesion of the bowels to each other and a large accumulation of fluid between the parietal and visceral peritoneum and that the parietal peritoneum was largely thickened and that this had been stripped from the abdominal wall, as Dr. Baldy himself thought. The peritoneum in these cases does become greatly thickened. Some of his own cases suggested this view.

Dr. Harris A. Slocum suggested that a possible explanation of Dr. Baldy's case of peritoneal cyst is congenital enlargement of the urachus. He could understand how such a condition might occur—first enlargement, and then malignant change. Under such circumstances there would be found marked adhesion in the middle line.

Dr. Joseph Price said that tubercular peritonitis often simulates cystoma. It was his impression that this was a case of tubercular peritonitis.

Dr. J. M. Baldy said that it had always been his custom to open chronic abscesses. In the vast majority of cases the appendix is already destroyed. He

could have gained nothing by opening the general peritoneal cavity.

In regard to the second case he was rather inclined to regard it as malignant and not tubercular. The ovary was undoubtedly malignant, and it seems right to assume that the rest of the disease was also of a malignant nature.

Dr. Joseph Price presented specimens of extra-uterine pregnancy. These specimens are of interest, he said, and there were a few points about them that he would like to discuss. In the first place as to position; he thought they are primarily all tubal. In looking over the literature of the subject, he finds that there is a disposition among prominent operators to drop down from the position they once held in regard to intra-ligamentary or broad ligament rupture As yet Dr. Price had the first *broad ligament* hæmatocele or extra-uterine pregnancy to meet, and this with an experience of eighty-two cases. Rupture takes place at all points of the tube except at the crest of the ligament, which he believed to be the strongest portion. The pavilion extremity is the most common seat of rupture.

In these cases death is a matter of hæmorrhage and shock. The escape of a pint of blood into the peritoneum will sometimes kill, while a hæmorrhage of a quart from the vagina or uterus will not kill. The peritoneal cavity will not tolerate this blood. It is something aside from the mere loss of blood that kills. The danger from hæmorrhage is the chief danger. Until this summer, suppuration had not occurred so often in his experience. The last three cases, in which there was pre-existing tubal and ovarian disease, had suppurated. He was satisfied that there was an advanced form of tubal disease, which favors tubal pregnancy and also favors suppuration of the placenta and fetus after rupture. The quiescent cases that suppurate and come through the bladder and bowel are unfortunate cases. In many there is a fecal fistula.

The child free in the abdomen is quite a common occurrence. In Jessop's case there was a live child free in the abdomen. Three or four such cases have been reported. Dr. Price thought there was a case of Dr. Atlee's in which a child weighing nine pounds was found among the intestines.

Elliston J. Morris,
Sect'y.

THE SURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, Sept. 12th, 1892.

The President, Dr. A. M. Cartledge, in the Chair.

SYPHILITIC CASES.

Dr. I. N. Bloom: I simply want to exhibit this patient to illustrate a point that has been very much misunderstood; at least the syphilid has been called by various names. There seems to have been a great deal of confusion between the forms of syphilis known as serpiginous and tuberculous. There is really no such thing as a tuberculous syphilide. The term is applied to a form, rarely met with, a type of which is shown in Kaposi's atlas. This patient gives the history of syphilitic trouble of three or four years standing.

The infiltration all around the orifice of the anus and perineum is that of condylomata lata.

No. 2. This little colored girl came to me on the second day of August last, and I made diagnosis immediately after seeing the lesion on the cheek; it has since been confirmed. When she consulted me there was this induration which you see on the cheek, and a few enlarged glands on the neck, nothing else. I made a diagnosis of syphilis from the initial lesion on the cheek. She gave the history that some time before she had a fight with another colored woman and was bitten on the cheek. I gave her powdered chalk, bread pills and other things to hold her, continuing this treatment for three weeks, when the eruption appeared on her body, making the diagnosis absolutely certain. She was not put upon specific treatment until after the eruption appeared. The date of her altercation preceded the appearance of the local lesion about four weeks, or two months before I saw her. It would be an interesting case if we could make an examination of the woman who bit the girl, I doubt not we would find decided evidences of buccal syphilide. We made every effort, but could not find her assailant. This is the first chancre that I have ever seen on the cheek, but they have been reported not infrequently. There is still considerable enlargement of the glands of the neck, but the induration of the cheek has grown less and less since she

first commenced specific treatment, a little less than a month ago. There has been no enlargement of the glands in the groin.

It seems to me this is a perfectly clear case of syphilitic lesion; girl, eighteen years of age, otherwise seemingly in excellent health; does not claim to have been virtuous, but as far as she knows, has not been exposed to any disease through coitus. There appears, some time after a bite, a sore on her cheek, which is a painless, indurated, non-ulcerative enlargement, and, in addition to this, a very great induration of the glands of the neck. I am consulted two months after she was bitten, and, in three weeks send her to the hospital, at which time the enlargement of the glands and the syphilide on the cheek were twice as large as they are at the present time. The glands on the neck were enormous, so large that you could see them as far as you could distinguish her features, on both sides of the neck, but larger on the side on which the chancre appears on the cheek. Before being sent to the hospital, she came to see me every two or three days, and I was constantly watching for an outbreak upon the body. I attended her at the hospital. I told her that such a breaking out would occur eventually, and it did occur. It was followed by scabby sores on the head and condylomata upon the genitals, both larger labia being involved. This condition of things led me to put her upon specific treatment, which has caused a disappearance of the indurated condition to a great extent. The history, it would seem to me, excludes anything else but syphilis, and makes it as a clear a case as is possible, without confrontation.

DISCUSSION.

Dr. J. G. Cecil: I cannot but agree with Dr. Bloom in his diagnosis of this case; I think, according to his statements, there can be no reasonable doubt about it. I should be very much pleased if we could get hold of the other party in the case.

Dr. E. R. Palmer: I really do not know that I have anything to say regarding the case: (Second case exhibited by Dr. Bloom). The condition of the local sore now is absolutely negative. In the local sore I cannot conceive any feature of syphilis, either early or late so far as any initial lesion is concerned, but the woman is undoubtedly syphilitic. I see so few colored people, and of course they are often seen by Dr. Bloom in his hospital service. The condition of the glandular enlargement is such that this alone would not justify anything in the diagnosis of syphilis. Except for my entire confidence in Dr. Bloom's ability to make a diagnosis, I would not be prepared to say that the scar on the cheek was a chancre, but I recognize the extreme possibility of the occurrence of chancre anywhere, where the infection might be applied, and, in view of the history of the case, I think there is no reasonable doubt but that this is the initial lesion. The mastoid glands are not enlarged on either side as far as I can determine now. In fact, the case is a little too far along to make any positive diagnosis, except on the history. Dr. Bloom's history of the case, I think, makes it perfectly clear that the initial lesion occurred at that point, (on the cheek), but I must say that in the sore, as I see it now, there is no physical evidence of its being a chancre. We all know the tendency to strumous trouble in colored people, and their liability to symmetrical adenitis. While this patient has shown secondary manifestations for three months, and been under treatment, no Doctor has the right to say that it is or is not syphilis, just from the case as it presents to-day. I think the day is not far distant when syphilis will be taken from the class known as venereal diseases.

Dr. I. N. Bloom: I think it all points to infection of recent date.

Dr. E. R. Palmer: It is unquestionably infection of recent date. I think I can quote Dr. Bloom when I say that it is exceedingly hard to find a vaginal initial lesion. Dr. Bloom has shown me one or two cases of local vaginal lesion, and Dr. Bullock brought in a case some time ago with a chancre on the labium minus. It is exceedingly hard to find the local lesion in the female.

Dr. I. N. Bloom: I want to indorse what Dr. Palmer has said, that in the woman you often find evidences of recent syphilis where there is no evidence of the initial lesion. As a case in point, I will mention a girl whose history I knew very well, knew also that she had not led a virtuous life. A man had been sent to me suffering from iritis; he had been treated but received no benefit; he denied absolutely having had a sore of any kind. Upon examination (he having come

directly from the oculist), I found a few scabs in the hair; found syphilide on his body; found a mucus patch in the corner of his lip; he had this iritis and a universal glandular enlargement. He told me that he had had no intercourse with any woman, except one, since Easter day. In my absence, my assistant examined the girl, and found absolutely nothing. Not knowing who the girl was and feeling as I suppose all doctors do, that they are not thoroughly satisfied unless they make an examination themselves, I requested this man to bring the girl to my office that I might make a personal examination. This was done and much to my surprise I found it was the girl above referred to, whom I knew very well. I made a thorough examination and could find no trace of syphilis of any kind whatever. The man had no chancre as far as I knew, but he had unmistakable evidences of syphilis. I do not know where the syphilitic virus entered, but there was no doubt as to the presence of syphilis. Another case I recall came to me with diagnosis of cancer of the tongue, and yielded promptly to six months' mixed treatment; that is, all traces of it disappeared. In this case there was absolutely no history of chancre, but it was unquestionable syphilis.

Dr. Anderson will remember a case that I sent to him on one occasion, a young man; I made the diagnosis, yet I know it was syphilitic trouble. The man died of typhoid fever about six months after Dr. Anderson saw him. I do not doubt that there are many men who are perfectly honest in saying that they have never had a sore, yet, there are unmistakable evidences of their having syphilis. In women I believe that more chancres are overlooked than discovered.

In the second case reported by me, I think the sore is a typical induration and can only be attributable to one cause, syphilis. I think a chance can be of the Hunterian type on the cheek as well as on the penis. Concerning the enlarged glands of the neck—we would naturally expect a greater enlargement on the side on which the chancre is situated. Glandular enlargement is produced through the lymphatic system, and I believe, if Dr. Palmer will think a moment, he will remember a case we saw together having a severe chancre on the penis on one side, and the enlargement in the groin on that side was very much out of proportion, very much larger, than the glandular enlargement on the other side of the groin. Referring again to the case under discussion, I do not see what the sore on the cheek could be except chancre; I would have nothing else to suggest. I do not see what could produce that form of induration which is left. Taking the case just as it appears now without any history, without any syphilide on the body, without any history of the effect of the mercurial treatment, simply the sore on the cheek and the glandular enlargement, I think the suggestion would be initial lesion. It does not look like eczema or any form of furuncle, or, in fact, anything except chancre; there has never been any sensitiveness or evidence of pain on pressure. The simple existence of these two conditions—the enlargement of the glands, and induration on the cheek I think suggest syphilis. I agree with Dr. Palmer that the day is probably not far distant when syphilis will be taken out of the class known as exclusively venereal diseases.

Dr. A. M. Cartledge: I believe this is a case of syphilis with the initial lesion on the cheek. However, I do not know whether I would have been inclined to consider it syphilitic trouble, had not Dr. Bloom given us the history in detail.

Fibroid Tumor.

Dr. Turner Anderson: I present here a sub-mucous fibroid tumor removed from a woman thirty-four years of age, who had been in the care of an irregular practitioner who made diagnosis of pregnancy; the patient was a widow and about as far above suspicion as possible. Upon examination I found this tumor which was removed without great difficulty, promptly relieving the case. The tumor was found beneath the mucous membrane and was without a pedicle. I secured it with a pair of forceps, pulling it down as low as possible, separating the adhesions with my finger, believing this to be the safest way. There was continuous hæmorrhage for several weeks before I saw the patient, none afterward.

Traumatic Aneurism of Cheek.

Dr. W. O. Roberts: At the annual

meeting of the Medico-Chirurgical Society during the spring, Dr. Anderson exhibited a patient (little girl) suffering from traumatic aneurism of the cheek. The history of the case was about as follows: When the child was seven years old she was struck on the cheek with a stick, a swelling immediately raised and never disappeared. At the time the patient was exhibited which was seven years after receipt of the injury, those of you who saw the case will remember the strong pulsation of the tumor, and the thinness of the tissues superficial to it. Compression of the anterior temporal artery would cut off pulsation of the tumor. It was advised by the surgeons present at the meeting that an early operation should be performed, otherwise the tumor would increase in size, and eventually the skin would give way. I saw the case with Dr. Anderson last Thursday at the St. Mary and Elizabeth Hospital; found the growth had considerably increased in size, there was also a dilated condition of the smaller vessels on the surface extending some distance beyond the tumor itself. The skin the growth was very thin and bluish in appearance. An operation was performed at once, Dr. Butler administering the chloroform, Drs. Anderson and Bullock assisting. I made a long incision directly over the central portion of the tumor and carefully dissected it out. I think there were eight vessels ligated; hæmorrhage very slight, and the patient has done uninterruptedly well since the operation.

SPECIMENS.

Dr. W. C. Dugan: I have three specimens to exhibit: No. 1. Sarcoma of the kidney, removed on the 16th of last month at the Children's Hospital A day or two before the operation the patient was brought in from the country by Dr. Durrett for some obscure abdominal troubles, and upon examination we found in the side a large tumor extending under the costal cartilage and into the pelvis. Diagnosis of cancer of the kidney was made, and operation advised at once. Drs. Cartledge and Vance saw the patient and both agreed not only as to the diagnosis, but also as to the advisability of immediate operation. Operation was performed on August 16th, Drs. Vance and Cartledge assisting. I made an incision extending from the eighth rib down over Poupart's ligament, removing the tumor and a portion of the surrounding tissue, after ligating the pedicle; there was practically no hæmorrhage and no drainage tube was used; patient on the table about sixteen minutes. The patient was troubled at the time of operation with malarial fever, temperature 100.2° F., pulse 126 when she was put upon the table. I believe we made a mistake in operation on this patient when we did, and if I had it to do over again, I would put her on treatment for malarial fever for a number of days before submitting her to operation. After the operation her temperature went up to 103° and pulse to 166; however, she has done fairly well since, leaving the hospital on the twentieth day. Since her return home she has gained flesh and strength and is able to run and play as other children.

Specimen No. 2—This specimen is one of especial interest; it is the entire appendix, and I call particular attention to the shape of it, it was just as you see it when removed. The patient, I regret to say, died. On the 16th day of August I was called down near Jellico to see a young man suffering from what was supposed to be intussusception. I reached him on the 18th after forty miles jaunt over the mountains. I found the patient with pulse 110, very bad expression of the face, etc. Immediate operation was advised. He realized his condition as he had been vomiting fecal matter since the Sunday previous. It seems on the 11th of the month which was Thursday, he had a severe pain in the left side, which he attributed to having eaten a watermelon the day before. On Friday he was some better and able to sit up, but suffered pain and took an opiate. On Friday night a physician was called who made diagnosis of intussception; vomiting was excessive and he had no movement of the bowels whatsoever. He continued to grow worse and on Sunday he had stercoraceous vomiting; then one of his physicians came to town for me and I went out with him. Drs. Glass and Dailey, of Boonville, had charge of the case, and ably assisted me in the operation. I opened the abdomen and passing my finger down to the cæcal region, this specimen was brought up, there being no adhesions at all; it looked very much like a large leech, and you can all see the resemblance. There was no hæmor-

rhage at all, and caecal attachment very small and shows that it has been made small by being twisted. The young man was in such condition as to require very rapid operation, so he was off the table and in bed in a very few minutes. Now, the pathology of this is especially interesting:—You will (the appendix being cut open) notice here a large clot of blood; he had ulceration of the appendix, opening into one of the large blood vessels, which resulted in a hæmorrhage into the lumen of the appendix, ballooning it as it were, and he had this peculiarly developed appendix, which finally became twisted causing obstruction and gangrene. This shows how little is required to cause complete intestinal obstruction, as in this case there was nothing else, yet there was complete obstruction which was relieved by its removal. I left him in about two hours, seeming to be doing well, but there was still a very bad expression about the face. He had two large fecal evacuations that evening and night, and cessation of vomiting, but died the next day at ten o'clock in collapse.

Specimen No. 3—Next is an appendix removed from a patient who was under the care of Dr. F. C. Wilson. Dr. Wilson had made the diagnosis of appendicitis. There was no doubt about its being a case of appendicitis, as you will observe here an enterolith en situ. I was asked to see the case one week ago ago last Saturday by Dr. Wilson, and, upon examination, we found an induration in the right cæcal region. At the time the patient's pulse ranged from 95 to 100, temperature practically normal. Now, we considered this one of the "border line" cases, and advised the little fellow to be left without operation until the next morning, provided the symptoms did not change for the worse, when we would see him again. He was given that night ten drops of the tincture of opium, which gave him a good night's rest. The next morning he felt well, but on examination the tumor in the cæcal region was still marked, so we decided to delay operation no longer. There was little or no rise of temperature in this case at any time. I want to say that the doctor in this case had suspected cystitis at first, and had treated him for this condition, but upon examination, the urine was found to be perfectly normal. The patient was put upon the table and an incision made from middle of Poupart's ligament toward the anterior spinous process, hoping to find the pus or abscess extra-peritoneal. Doctor Kirk assisted in the operation; the peritoneum was separated from the iliac fossa which being opened and finding no pus the peritoneum which was much congested and rather protruded into the wound was opened, and to our surprise found a great deal of pus.

The patient had general suppurative peritonitis, there were a great many patches of lymph of a dirty gray color on the cecum, and the whole peritoneum presenting that peculiar dirty-gray appearance which we so often find in suppurative peritonitis. The cavity was thoroughly washed with hot water, and then the right cæcal region loosely tamponed with iodoform gauze. The operation lasted about twenty to twenty-five minutes. He was taken off the table in good condition apparently, having lost nothing by the operation; he remained so all that day, and had a very fair night up to twelve o'clock when there was considerable distension of the bowels. I saw him again at five o'clock at which time there was decided tympany. We introduced a tube into the stomach and relieved him of much gas and tried rectal injection of turpentine emulsion, salts and water etc., but septic paresis was profound and he grew rapidly worse, while the discharge from the wound was perfectly sweet. Patient died about six o'clock. The bowels were enormously distended, and we were unable to get anything through his stomach at all.

In the two cases reported, one had decided tympany, the other case no tympany at all. This makes eight cases of appendicitis I have had in the last two months, four of which have been fatal, making the mortality fifty per cent.

If an individual experience is to be relied on on, I am justified in coming to the following conclusions: First. The symptoms of appendicitis are variable and misleading, often times simulating cystitis, intussusception, internal strangulation, etc.

Second. The localized pain, "McBurney Point," is often absent. I am convinced that that symptom has been dangerously magnified. Many regard it as almost pathognomonic, and when not found, cases of appendicitis are left to the mercy of

accident and allowed to drift beyond the safety line before counsel is called.

Third. The sudden onset of an attack of severe colic, in the young, which does not yield in a few hours to medicinal agents should excite strong suspicion of appendicitis, and cause the physician to call to his assistance a surgeon and thereafter see the case together as often as it be considered necessary.

Fourth. I desire to place myself on record as most decidedly opposing the position of Drs. Loomis, Draper and Delifield in maintaining that these cases are medical, and should be under the absolute control of the physician, he saying when the surgeon is to operate.

Fifth. The first duty of the attending physician when he suspects appendicitis is to call a surgeon, for if he waits for the "beginning of sepsis or shock," or signs of perforation, etc., etc., he had almost as well not call him at all. If the physician waits until he considers an operation necessary, oftentimes he has delayed too long, and, too, it is always desirable that the surgeon become somewhat acquainted with his patient's temperament, etc., before the operation.

Sixth. The presence or absence of temperature is of little or no insignificance. It is not unusual to find large accumulations of pus with sub-normal temperature in these cases—a fact not generally appreciated. If every case of appendicitis, catarrhal or suppurative, were subjected to early radical operation, fewer deaths, by far, would result than under the present method of so-called conservative treatment. No stronger argument could be produced in favor of early operation than our inability to examine an abdomen and say what condition exists within, and the high rate of mortality in these cases, if left to medical treatment alone. Some of the most severe cases, to judge from the subjective symptoms, prove to be nothing more than an intensely congested appendix, whereas, some of the mild, "compartively" safe and "comfortable" cases, were found to be diffuse, suppurative peritonitis, with perforation; therefore, I maintain that since we are unable to diagnose the condition, and since exploratory operation under favorable surroundings, and in skilled hands, is not dangerous, I desire to enter a plea for early operation.

SPECIMENS.

Dr. W. L. Rodman: The specimens you see here are several enlarged glands that I removed from the left inguinal region of a man about thirty years of age, a few days ago. The enlargement of these glands followed an attack of gonorrhœa: they were easily dissected out, and I did it almost entirely with my finger. The wound was thoroughly washed with 1 to 500 chloride of zinc solution, the patient being up and around the hospital in three or four days. There was not a drop of pus. I consider extirpation decidedly the best plan of treatment for these enlarged glands, and have been doing the operation for several years, with excellent results.

No. 2.—Here are two sections of veins, each of them taken from patients suffering from varicocele. The bloody one was removed to-day, and was the most extensive varicocele that I have ever seen. I brought the ends of the veins together by means of a continuous buried suture, finally closing the wound, also with continued suture, without drainage. There was not a drop of pus, and I think the result will be all that could possibly be hoped for.

Dr. H. H. Grant: What do you want to bring the ends of the veins together for?

Dr. W. L. Rodman: For the purpose of holding the testicle up.

TETANUS DUE TO PUNCTURE WITH A HYPODERMIC NEEDLE.

An instructive case is reported in a recent number of the *British Medical Journal*. A patient who had been in the habit of injecting morphine hypodermically into himself came under observation with symptoms of tetanus which eventually resulted in death. A careful search revealed no other cause for the tetanus than a small inflamed and suppurating place near the shoulder, which had been caused by one of the hypodermic injections he had given himself. The lesson taught by this case of the importance of the observance of scrupulous cleanliness, even in so small an operation as a hypodermic injection, cannot be too strongly impressed, and the memory of the disastrous effects which may result from the neglect of proper precautions should be firmly fixed in the mind of every practitioner.—*Omaha Clinic.*

By M. B. WERNER, M. D.

Death ending from Acute Mercurial Poisoning, due to the Local Application of the Grey Salve (*Berlin. Klin. Woch.*, 1892).—Jan. 15. Female, æt. 20, suffering from cracks in hands and pain in the forearm, was advised to use the salve. One hour after its local application nausea, faintness, and vomiting set in. Admitted on the same evening to the hospital at Breslau; vomiting continued, repeated fainting attacks, hand and lower third of forearm swollen, doubtful fluctuation; incision shows cellulitis. Jan. 16. Vomiting continues; albuminuria, tenismus; evening temp. 36.6°. Jan. 17. Bloody stools, colic, anuria; temp. 36.2°. Jan. 18. Hæmatemesis; continous bloody stools. Jan. 19. Gangrenous gingivitis; anuria continues. Jan. 20. Death. Section the lower portion of the small intestine—hemorrhagic spots; superficial necrosis of the mucus membrane; the large intestine showed the grave picture of dysentery; kidneys showed necrosis of epithelium. The cause given for this grave train of symptoms, following only one application, is that it was applied on the broken surface.

Albuminuria during Pregnancy Treated by Internal Administration of Chloroform.—Duff (*Med. Neuigk.*, Sept. 17, 1892) reports the satisfactory results in five cases of marked albuminuria accompanied with convulsions. He gave in solution 0.8 gr. every hour; the convulsions ceased in a few hours and the secretion of urine increased. All were able to go to the end of their term, and in all the albuminuria disappeared after parturition.

Ballay and Lerefait (*Med. Neuigk.*, Aug. 1892) have treated whooping cough for months with creosote with surprising good results. In thirty cases Lerefait asserts that the most grave cases lasted never longer than six weeks, and usually only one or two weeks. Its first effect is to arrest the vomiting, and the number of attacks of coughing are reduced from sixteen and eighteen to three and four daily. It is given in syrup:

℞ Creosote..... 0.50
Syrup .....100.

M. S.—Two to three teaspoonfuls in children six weeks to two months, six to eight teaspoonfuls as they are older.

Ballay adds wine to the mixture.

Treatment of Tuberculosis of the Lungs by Antiseptic Inhalations.—Delthil (*Med. Neuigk.*, Sept. 24, 1892) reported before the Academie de Medicin his method, by which he claims a marked improvement and prolongation of life:

℞ Ol. terebinth.....350.0
Ol. lavandul.....100.0
Iodoform..... 10.0
Sulph. ether .... 20.0 M.

This mixture, impregnated with the air breathed, will reduce the quantity of tubercle bacilli, and even changes their appearance under the microscope from their normal comma to olive-shaped in the space of five to ten days.

GONORRHŒAL VULVO-VAGINITIS IN YOUNG GIRLS.

Epstein (*Abst. in Centralblatt f. Chirurgie*, 26, '92) has observed gonorrhœal vulvo-vaginitis in newly born infants, in whom it should be distinguished from the discharge produced by the desquamation from the vagina, which occurs in the first few days after birth. This latter sometimes has the appearance of pus, but the microscope shows it to be made up of epithelial cells. Through neglect of cleanliness, however, this desquamative catarrh can lead to a real purulent, though non-specific vaginitis. The gonorrhœal infection of the genitals of baby girls probably occurs in the same way as that of the eyes, namely, during the passage of the child through the cervix and the vagina. Epstein believes that this occurs more frequently than is commonly supposed, and that a part, at least, of the cases of gonorrhœal vaginitis in somewhat older girls are the result of an overlooked and neglected infection at birth. [For the difficulty in tracing the origin of these infections in young girls we can vouch from personal experience, and for some of them Epstein's theory may hold; in general, however, the precocious small boy and hired-man theories seem more plausible.] Epstein makes the reasonable suggestion that with gonorrhœal mothers, care should be taken to prevent infection of the infant's vulva as well as the eyes.—*Omaha Clinic.*

Bacteriological Notes.*

Etiology and Treatment of Tetanus :—In the *Transactions of the International Medical Congress, 1891,* Sig. Sormani presents some very interesting facts concerning the distribution of the tetanus bacilli and the effect produced upon their virulence in passing through the intestinal tract of animals. The tetanus bacillus exist in the upper layers of the soil, especially where it has been manured or infected. By rolling on the ground and subsequently licking their bodies, dogs and other animals introduce the bacilli into their alimentary canal and later deposit them again in the feces. The very interesting statement is made that the virulence of the bacteria becomes diminished in the gastric juices and afterwards resume their virulence in the intestine. If animals are withheld from any exposure to fresh infection, their feces will remain virulent for a considerable time. Rabbits have been infected with tetanus from the feces of dogs that had been confined for sixteen days. Tetanus bacilli invading the respiratory tract do not infect unless they are able to penetrate the tissues. Most cases of this disease have been acquired by wounds becoming infected by manured earth. As tetanus bacilli are extremely resistant to the ordinary disinfecting solutions, and are only destroyed with rapidity by iodoform and an acidulated solution of corrosive sublimate, the treatment should be to scrape the wound and after washing thoroughly with the antiseptic solution sprinkle it with iodoform. Although the article contains little not heretofore known, it is suggestive in the direction of prophylaxis.

A Gas-producing Bacillus (*Bacillus aero gener capsulatus Nov. Spec.*) capable of rapid development in the blood vessels after death :—Welch and Nuttall (*Bulletin of Johns Hopkins Hospital,* VIII, 1892, p. 81) describe a bacillus which they found in the blood of a man who died in the hospital in Oct. 1891. This bacillus is of considerable interest as it multiplies in the blood very rapidly (after death) and produces a large quantity of gas. It thus explains the cause of the occasional appearance of gas in the blood-vessels after death which could not be satisfactorily attributed to post-mortem decomposition. Coverglass preparations made from heart's blood and properly stained showed a large number of bacilli; from three to five micromillimeters in length and about the thickness of anthrax bacilli, with ends slightly rounded but sometimes almost square cut. The bacillus is not motile; capsules were sometimes observed about the bacteria. The bacillus grew on all of the ordinary culture media. It grew best at a temperature of 35° to 37° C. It is anærobic. No growth took place in plain or sugar agar without first removing the oxygen. It forms no spores; the vitality of the cultures was of variable duration. It was destroyed in bouillon cultures heated to 58° C. for ten minutes. From inoculation experiments on rabbits the authors do not consider this bacillus as pathogenic for healthy rabbits under ordinary conditions. Rabbits were inoculated with certain quantities of a bouillon culture in the ear vein, killed after from two to five minutes and placed in an incubator. In the short space of six hours after death gas and bacilli had developed, the latter in enormous numbers.

Preserving the Malaria Parasite Alive.—Rosenbach (*Berlin klin. Wochenschrift, No. 35, 1891*) calls attention to the fact that the plasmodia which produces malarial fever can be preserved in the living condition in the blood extracted by leeches. In a case of typical tertiary ague the author placed a leech over the spleen. It died in 48 hours and within it numerous dead plasmodia were found. Two other leeches were applied some hours before the beginning of the attack, one of these was opened in 24 hours and found to contain a very large quantity of red blood corpuscles, a large portion of which included living plasmodia and mobile pigment. The other leech was opened in 48 hours. It presented a similar condition. A leech applied 24 hours after the treatment with quinine was found to contain a few shrunken organisms. From these facts the author suggests that human blood rendered artificially coagulable by each subtraction might be used for a cultivative medium for malaria parasites.

Sporeless Anthrax.—In 1873 it was demonstrated that anthrax bacilli culti-

* Translated for The Medical and Surgical Reporter.

vated in bouillon containing 1–2000 of bichromate of potash lost their faculty of producing spores. Their virulence, however, was not changed. Roux (*Annal. l' Institute Pasteur 1890, p. 25.*) has more recently produced a similar condition by the use of carbolic acid. His experiment briefly stated is as follows: ten test tubes containing bouillon to which carbolic acid had been added in variable quantities from 0.02 to 0.20 per cent. After sterilization they were inoculated with anthrax and placed in an incubator. The tube containing the greatest quantity of the acid remained clear, that containing the least developed bacilli with spores while those containing the intermediate quantity of carbolic acid developed sporeless anthrax bacilli.

The result of this experiment is important in illustrating the physiological and morphological aberrations in certain bacteria. It points still further to the effect that may be produced upon ordinary intestinal bacteria when their environment is changed either by medicines or an inflammation of the intestinal mucosa. It also indicates that changes in the environment of bacteria may endow them with characters, morphological and otherwise, which will separate them from the standard by which they are recognized.

EPILEPSY MISTAKEN FOR URÆMIC CONVULSIONS.

After reporting two cases of epilepsy with albuminuria, mistaken for uræmic convulsions, Dr. James Tyson says: (*Medical News,*) that so far as any peculiarity of the convulsions themselves is concerned, there is no way of avoiding errors. The uræmic are in fact typical epileptic convulsions exhibiting the same varieties and degrees. But true uræmic convulsions do not repeat themselves at intervals of months or years at a time, and yet leave the patient apparently no worse for his experience. And if true epileptic convulsions happened to be accompanied by albuminuria, such albuminuria does not as a rule remain at a standstill, or grow gradually less, but increases, and is associated after a time with other phenomena of chronic Bright's disease, such as hypertrophy of left ventricle, œdema, and high vascular tension.

Abstracts.

DENTITION IN INFANTS.

Upon the questions of difficult dentition and gum lancing, the medical world has been for some years divided; the smaller party taking the modern view that dentition is a normal process and rarely if ever produces dangerous symptoms; the larger party holding that dentition is responsible for most of the ills that infants suffer from, and that gum lancing is its sovereign remedy.

It is undeniable that at the period in life when dentition is in progress, the infant is subject to certain disorders which occur much more commonly than at any other period of life.

We think it can be said, however, without fear of contradiction, that there is not a single positive observation which has ever been recorded to prove that dentition produces general or reflex symptoms.

If it could be shown that dentition was the only peculiar condition of the infant, then its causative influence would be clear. But dentition is not the only peculiarity and coexisting phenomena can only be classed as coincident. The most profound characteristic of infancy is that it is the period of most rapid growth and development of all organs; and careful observation of infants reveals numerous and great deviations from the normal growth and development in many instances. It will probably not be denied that such deviations are found most commonly in infants who have been artificially fed. In infants improperly fed, and this term is too extensive to attempt to define here, reflex manifestations are very readily produced, and it is not improbable that even a normally developing tooth may, in such an infant, be the exciting cause of trouble. We have seen infants, who would invariably have a bronchial attack immediately before the proruption of a tooth, but they have invariably been infants who were suffering from demonstrable deviations from normal nutrition. We have further found that after improving the nutrition of these infants, the further progress of dentition was unaccompanied by symptoms.

In such cases while it would be just as well perhaps to recognize the possible influence of dentition, its subordinate impor-

tance should be kept clearly in view. The great danger of teething is in the diagnosis, for when this is once made the important underlying conditions are apt to be neglected, and permitted to progress to the death of the child.

Dentition is a convenient scapegoat, and Olliver has well said: "During the nearly ten years that I have been connected with the Hospital for Sick Children, it has often happened that children brought to me for diseases of this type (teething) have been found to be suffering with an altogether different affection. It is very easy to invoke this diagnosis, but by passing in review the different organs and apparatuses, the diagnosis can easily be rectified."

But if dentition cannot be shown to be the great etiological factor of infantile disorders, it does not follow that gum lancing should be abandoned. It is difficult to overlook the numerous instances in which careful observers have thought they have obtained good results from its use, but it would be well also to bear in mind the many cases in which it has failed. As a therapeutic procedure it may have some value, but the indications for its use must be sought elsewhere than in a supposititious condition of teething. We should like to offer the following conclusions:

1. Before the diagnosis of "teething" is made, there should first be carefully excluded, organic diseases of all organs, infection, intoxication, and perversion of nutrition.

2. Gum lancing as a therapeutic measure should stand on its own merits, and be studied apart from any supposititious and undemonstrable process of teething.—*Journal Amer. Med. Ass'n.*

ICHTHYOL IN DISEASES OF WOMEN.

Drs. Reitman and Schönauer experimented with ichthyol in acute and chronic inflammatory diseases of the uterus and its appendages, and are quite satisfied with its efficaciousness. They tried it with success in parametritis, pelveoperitonitis, oöphoritis, salpingitis, periöphoritis, perisalpingitis, as well as retrouterine and periuterine exudates, chronic metritis and cervical erosions. The following formula was used:

℞ Ammon. sulpho-ichtholy.....5 jiss.
Glycerin.....f ʒ iij.
Sig.—For external application.

—*Zeitschrift fur Therapie,* No. 18, 1890.

THE TREATMENT OF ALCOHOLISM BY DRUGS.

The *British Medical Journal* makes some excellent points in noticing a recent work upon this subject by Dr. J. E. Usher, of Melbourne. No one drug is regarded as a specific. Each case must be studied by itself, and such measures adopted as are especially adapted for its peculiarities. The author regards it of the first importance that the patient have a real desire to be cured. No treatment can succeed without the existence of this desire; hence the first thing must always be the strengthening of such will-power as the patient may possess. Harshness, threats, and abstraction of sympathy are all out of place in such cases. Dr. Usher for four or five days gives nux vomica; at night he gives bromide of potassium or some other sedative, if needed for sleeplessness. He thinks that the best hypnotic is hyoscine, given hypodermatically in doses ranging from one one-hundred and-fiftieth of a grain upwards. If absolutely necessary, one ounce daily of whiskey or brandy may be given. After the fifth day a mixture of manganese and strychnia is indicated for two or three weeks. Iron is given when a tonic is called for. Euonymin with pepsin is found needful when hepatic symptoms are prominent.

The nitrate of strychnia is used hypodermatically by many close observers. With it is combined, sometimes, atropine. Often a mixture of tinctures of cinchona and iron appeases the appetite for drink.

In general, the first object sought is the breaking of the vicious habit; and, second the neutralizing of the immediate ill effects which may follow the dropping of the accustomed stimulus. The first end can be obtained only by a determined effort of the patient's own will. Drugs may be of service here in making him so sick that he cannot enjoy the use of alcohol: in doing this care must be taken that drugs be not used which endanger the patient's health or life The use of strychnia as a substitute for the alcoholic stimulant to which the nervous system has become accustomed, has a rational basis. The use of morphine, cocaine, etc., may be beneficial under certain circumstances, but is fraught with the danger that a new habit may be formed worse than alcoholism.

The *Journal*, however, relies not so much upon drugs as upon the diffusion of knowledge, well directed legislation, and improvement of the lives of the people so that they may not crave drink to overcome the discomforts of bad digestion and the worries and anxieties of daily life.

CASE OF HYDRAMNION IN TWIN PREGNANCY.

Dr. Everett J. Brown, in *North American Practitioner*, Sept., 1892, records a case of a patient æt. 34, mother of two children, youngest seven years of age.

Physical examination revealed an enormous abdomen, œdema of feet and hands, body temperature 102° F.

Vaginal examination revealed the cervix completely dilated, the finger coming in contact with a very tense bag of water. The membranes were ruptured, and was followed by an astonishing gush of water. He estimated, that at least eight quarts was passed; the relief to patient was immediate. Regular labor pains began, and were soon followed by the birth of two fœtuses, weighing two and three pounds. There was only one placenta, both children were females and were probably unioval twins. The puerperium was uneventful, the patient being up in nine days.

All œdema of extremities disappeared.

TWENTY-FIVE CASES OF EXTIRPATION OF THE UTERUS FOR CANCER.—A CONSIDERATION OF ULTIMATE RESULTS.

Dr. Charles A. L. Reed, of Cincinnati, presented to the recent meeting of the American Association of Obstetricians and Gynecologists, a report of twenty-five cases of complete vaginal extirpation of the womb for cancer with only too primary deaths—one from shock and one from iodoform poisoning. Of the twenty-five operated upon, but fourteen were of more than two years standing, and hence were all that could be discussed with reference to their ultimate results. These fourteen were divided into two classes, of seven each viz., those in which the disease had existed for more than six months before the operation and those in which it had existed for less than six months before the operation. Of the first class, i. e., those of more than six months (an average of 10 months) previous duration, all were dead; of the second class, i. e., those of less than six months (an average of 4 months) previous duration, only on had since died. One of the recoveriese is of more than five years duration. The conclusion from these figures is that the cases of cancer of the uterus ought to be remanded for operation as soon as diagnosed. Dr. Reed looks upon total extirpation as the only operation to be advised or practiced in these cases, the primary mortality from which, in experienced hands, varies from five to eight per cent.

SOME PRACTICAL POINTS IN THERAPEUTICS.*

By JNO. A. LARRABE, M. D.,
LOUISVILLE, KY.

The author, in conclusion, made mention of those therapeutic agents which, during the summer months, had been so successful, in his hands. In entero-colitic diarrhœa—the so called "summer complaint" of cities, dependent upon the various micro-organisms, vitiated air, and bad food—salol, napthaline, carbolic acid calomel, in minute doses, and nitrate of silver stood the test.

In gastro-enteritis, he found salicylate of bismuth useful and in inflammatory diarrhœas of infants and older children Rochelle and Epsom salts, in acid infusion of roses with small doses of laudanum. In chronic cases, the nitrous acid camphor mixt. (Hope's) did not fail. For gastric fevers so common in children the preparations, ammonia-phenique, and sulpho-phenique, were used with better success than any other treatment.

He also used this treatment very satisfactorily in the exanthemata.

In diphtheria, peroxide of hydrogen and whiskey internally gave him the best results. Disappointment in the use of the peroxide, is often due to the poor quality of the drug. It is a very unstable article. It should always be purchased in small amounts protected from the light, by being put up in 4oz bottles. On coming in

*Abstract of a paper read before the Louisville Medico-Chirurgical Society.

contact with the false membrane of the throat, a white foamy reaction takes place. It should be freely applied to the throat on mops or by use of spray. The crying and resistance of the child, favors the distribution of the fluid. In this way the author has treated successfully a great many cases of diphtheria. He believes that the symptomatic use of definite, although often toxical, doses of whiskey, in children even of tender age, to be the surest safe-guard against heart failure.

Selected Formulæ.

CORYZA, CEPHALALGIA AND ASTHMA.

Dr. Coupard (*Münchner med. Wochenschrift*, No. 12, 1892) recommends in asthma, coryza and cephalalgia the following powders:

℞
Cocaine hydrochlorate.....grs. ij.
Menthol.....grs. iv.
Boric acid.....grs. xxx.
Finely powdered roasted coffee.....grs. viij.

EXTEMPORANEOUS GLYCERIN SUPPOSITORIES.

M. Romer contributes the following to the *Pharmaceutische Post:*

℞
Anhydrous sodium carbonate..... 1 gm.
Stearin, rasped..... 2 "
Alcohol.....15 "
Glycerin, q. s. to make.....60 "

Mix the sodium carbonate and stearin, and pour the alcohol over them Heat the mixture in a water-bath until the alcohol is driven off, then add the glycerin and continue the heat until a limpid solution is obtained. Pour into molds. The quantity indicated is sufficient for four suppositories for adults.

THE TREATMENT OF SOFT GOITRE BY PARENCHYMATOUS INJECTIONS OF IODOFORM.

Prof. v. Mosetig-Moorhof (*Le Bulletin Médical*, No. 36, 1892) proposes parenchymatous injections of the two following solutions in the treatment of soft goitre:

℞
Iodoform.....1 gm.
Ether } āā .7 gms.
Olive oil }

℞
Iodoform.....1 gm.
Ether.....5 gms.
Olive oil.....9 gms.

The writer, however, has only used the former solution, and in sixteen cases treated by him (ten men and six women) the results were excellent. In two months the necks of all the patients had diminished six centimetres in circumference. Two months later this had attained eight or ten centimetres. The goitres did not regain their former volume even six months after cessation of the injections. A syringeful is injected into each goitre, and in one case of enormous goitre six grammes (1¾ drachms) were injected. This is repeated every four to six days; some of the patients received one each day for several days without any bad results. No disagreeable action was noticed.

CONTUSIONS OF THE SCALP.

Dr. F. F. Lawrence concludes as follows (Columbus *Med. Jour.*) on this subject:

1. Contusions of scalp caused by slight blows or falls, accompanied by moderate amount of effusion, are simple and require little treatment.

2. Contusious of scalp caused by sharp blows or severe falls are always to be examined carefully, and a guarded prognosis given.

3. Those accompanied by large effusions, and especially if pulsating, should be treated by shaving scalp, incising, turning out clots, (examining carefully the pericranium and skull), securing bleeding points, closing with sutures, preferably braided silk, dressed with dry antiseptic dressing, which should only be removed when absolutely necessary, before the fourth or fifth day, when sutures should be removed, a light compress bandage applied,

4. Those accompanied by little or no swelling, when caused by severe blows, should be carefully watched, and on first appearance of local fever or swelling, freely incised, washed out and treated as open wounds.

5. If the case is not seen until patient has had chills, hot dry skin, hard pulse, fever coated tongue, nausea or vomiting, insomnia, nevous twitchings, or any other symptoms of meningeal inflammation, we should cut down and trephine at onec over site of injury.

6. While inflammation of either pericranium or the meninges, is one of the things likely to follow these injuries, it may be prevented by early incision.

7. Where caries of bone or meninges occurs, the cause may generally be found to be injury of pericranium, which became inflamed, effusion followed, then inflammation of vessels from pressure, and then by extension meningitis.—*Med. Review.*

THE
Medical and Surgical Reporter

ISSUED EVERY SATURDAY

EDITORIAL AND BUSINESS OFFICES:

29-35 N. Tenth St., Cor. Filbert, Philadelphia.

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, OCTOBER 29TH, 1892.

THE TREATMENT OF COMPLICATED FRACTURES.

The treatment of complicated fractures as advocated by v. Volkmann, is, that every complicated fracture should be operated upon primarily, the operation consisting in enlarging the wounded space, enough to admit the finger to search for and remove all loose fragments of bone, blood and clot. Should the fractured ends of the bone be sharp, they should be cut, provision for drainage should then be made.

Dr. R. v. Frey believing this method rather extreme, concluded to make some studies upon the results of antiseptic conservative treatment.

In the Grazer clinic all suitable cases were treated by the Volkmann method, with the result of slow healing often marked shortening and pseudo-arthrosis. These placed along side of cases sent in by country practitioners, in which the wound had been freely dusted with iodoform and bandaged, and which—after three or four days presented an aseptic condition—naturally created some doubts regarding the propriety of Volkmann's treatment.

The treatment now used at the above clinic is as follows: In the absence of much contusion to the soft parts, the wound is cleansed and disinfected, then powdered with iodoform, and dressed with iodoform and sublimate gauze.

If injury to the soft parts has deprived them of their vitality, such are removed, the wound washed out with sublimate solution, and if necessary, provision made for drainage.

Incision is only resorted to when there is reason to believe that foreign bodies have entered the wound, or the fracture has perforated into an articulation, or if symptoms of local infection present themselves.

As a rule bone sutures are not used; when, however, it becomes necessary, use such. Metal wire or Gussenbauer's clamps are used.

The author gives a list of forty-six cases: thirty by conservative treatment, sixteen non-conservative or by incision.

Among the conservative cases, there was one death from tetanus, one from phlegma; the remaining twenty-eight were cured, eighteen first intention, and in ten cases there was some suppuration owing to presence of sequestra.

Debridement was performed in nine non-septic and seven septic cases (cases were septic on admission.) Of the nine non-septic all recovered, notwithstanding one suffered from erysipelas; of the remaining eight there were five with slight, and one with marked suppuration; two without any. Among the seven septic cases there were four deaths (three from sepsis and one from tetanus). The remainder

recovered, one after secondary amputation, the other after long continued sequestra formation.

Of the thirty cases conservatively treated twenty-five were perfectly healed; in two, bony defects prevented a solid union; one tetanus case, and one case that left the hospital too soon, will bear evidence why the results were unsatisfactory.

Of the 9 non-septic cases treated by debridement, one healed with pseudo-arthrosis, the remaining 8 entirely healed; of the 7 cases (septic) treated by debridement, 2 were perfectly healed, 4 died, and 1 had amputation performed.

It is interesting to note that the number of conservatively treated cases, show no greater percentage of wound infection than those in which incision, drainage, etc., had been used; further, that of these cases there was but one of pseudo-arthrosis, and only in one-third of this number was there suppuration; whereas, in those cases where debridement was used this took place in one-half the number. There is also less shortening noticed in conservatively treated cases. The author concludes, therefore, that in the treatment of complicated fractures of the extremities, the rule should be conservative treatment; and the exception, debridement; the latter to be used only in special indications.

The destructive antisepsis should be only used when urgently called for; but in most cases it can be replaced by the conservative form of antisepsis.

UTERINE FIBROIDS.

Humans defines uterine fibroids as aggregations of normal uterine tissues in abnormal situations and masses. He says that operations are rarely, necessary, and among the indications for operations are hemorrhage when it threatens life, when unbearable from weight, when they cause serious pain and interfere with the digestion or circulation, obstruction of bowels, or when the pedicle becomes twisted.—*Brooklyn Medical Journal.*

Book Reviews.

Physician's "Complete" Book of Records, edited and compiled by Samuel E. Walker, M D., Philadelphia. Comprising Daily Call List, Daily and Monthly Cash Accounts, Obstetrical Record, etc., etc. Complete in one volume, bound in three-quarter Russia. Price, $5.00. Keystone Publishing Co., Philadelphia.

No class of professional men lose as much money, through faulty bookkeeping, as physicians. The chief reason for this lies in the fact that nearly all account-books made for the use of physicians are either so complex as to be constantly neglected, or so subdivided into Call List, Cash Book, Ledger, etc., that a regular bookkeeper alone can keep up the postings. Probably not one practitioner in fifty keeps his accounts in such shape that he can tell any patient, at a moment's notice, exactly how his account stands. This is not because the accounts of an average physician are complicated or extensive, but is wholly due to the fact that, so far as we know, a simple and yet complete method has hitherto been unknown. There are a number of systems extant which possess many points of excellence, but nearly all fail to cover the ground completely.

The new method, presented by Dr. Walker, seems to meet all the requirements of the physician with an average practice, and, appears to merit its title, "Complete."

The great feature of Dr. Walker's book is the system of keeping the entire record of each patient for each month, on one line extending across two of the broad pages. The first entry is patient's name and address; then memoranda regarding case, and following this thirty-one columns for recording visits during month, conveniently divided into morning, afternoon and night. Continuing on opposite page is the cash account, providing for payments on each or any of the thirty-one days, total charges for month, total payments for month, balance due at end of month, and also for subsequent payments, and transfer to succeeding month, if this be necessary. The actual time required for keeping this account will probably be not more than ten seconds for each patient, of not more than ten minutes a day in the practice of the average physician. We can see two great advantages in this system, viz: the physi-

cians current practice is daily under his eye, and closely grouped, instead of being widely scattered through a large book, and therefore no one is likely to be "overlooked," and each and every entry, being an "original entry," will be accepted in evidence by any court in case of suit to recover. There is no "posting," and, from the nature of the case, each patient's account appears every day exactly as it stands, all in one place, and complete.

The Obstetrical Record is compact and comprehensive, meeting all requirements. The Record of Deaths and General Memoranda, together with the extensive double index, make up a volume that will give great satisfaction to the profession generally. The book is very substantially bound having the "patent back" device whereby each section is mounted on a linen guard, rendering the book practically indestructible. The low price is much in favor of the success of this new publication, which, we are sure, will meet with prompt recognition on its merits.

Correspondence.

AN EDUCATIONAL NEED.

Editor of MED. AND SURG. REPORTER:—Certain epochs have taken the lead in certain lines of progression—in greatly improving of literature and advancing particular sciences and arts nearer perfection. There are periods in which there is something more than natural or historical growth—where there are evidences of great leaps.

Medically and surgically we acknowledge our great debt to the genius of the generations that have preceded ours. We have no disposition to decry or quarrel with our inheritance. We cherish the lessons of many great problems solved for us. But from these problems new corollaries have been evolved to be worked out by our better light. Many of the old systems have had their day. With the advance of civilization, the increase of populations and the change of modes of life, new modifications are needed to meet new or better understood conditions. When we consider the progress that has been made—what generations have done—the problems mastered, the lessons learned, which we have no need of unlearning, we have reason for the hope that we can do better than has yet been done. We are not ready to accept as fact that the processess of development and evolution in the medical and surgical profession have been worked out—that our science and art have reached completeness. The gratifying truth is that there has never been a time in the history of the profession when there was more vigor and intellectual activity than now, a very flood tide of high effort swells the veins of the profession. The question present and urgent is what lines can we adopt to hurry along our advances. The majority of the active and strong brained practitioners of every section of our country, of cities, rural towns and districts spend some time each year at some of our centres of medical and surgical education endeavoring to enlarge their professional knowledge in the clinics of our public and private hospitals. The spirit of inquiry and research is widespread. Only the *diluted mediocrity* of the profession is content with what is known. The desire pervades nearly the entire profession to gain more and better knowledge, familiarity with the more simple and accurate methods. By some cooperation, some organized plan, of our college and hospital authorities and our widely known clinicians and teachers, our visitors of the general profession would find much to tempt them into our midst. It is not possible to measure the great benefits that would accrue to post-graduates, to the general practitioners who visit the city for the purpose of improving their knowledge in general or in some specific line of practice, if the wards of our general and private hospitals were thrown open to them and they could be given the benefit of the bedside lessons and clinical teaching of our eminent teachers. We will not attempt to sketch a plan or mark out lines to be pursued; we will leave that to more competent hands. From the fact that the carrying out of some such idea as we have suggested would be in the interest of the entire profession and certainly in the interest of our medical colleges, the matter should command the attention of the profession. The men who visit us are not dull, but bright and earnest men, who come with an earnest purpose, and the only way we can perfect some plan to give them general and hospitable welcome and aid in promoting their educational plans is to begin.

Some plan certainly is possible in a great city famed for hospitality, philanthropic and educational systems. If a distinct institution could be so organized as to best serve the purpose that could be established. The enterprise would also have a commercial as well as a professional value, and thence of interest to the general business public. Nor are the social features, the widening of the fellowships of the profession, to be left out of consideration. The encouragements, strength gained by professional association, and the great benefits growing out of comparison of methods and results are not appreciated to the extent they should be. The interested association which promotes intimate acquaintance, softens professional antagonism and does much to drive out those vulgar jealousies which detract from the dignity of the profession. Such an institution in all its appointments and in its general management could be so conducted as to furnish an excellent theatre where could be brought into fellowship men of high character, talents and good work, many of national repute, both as specialists and general practitioners; where could be discussed those diseases which lie peculiarly within the field of medicine and as well those which by their very nature are without its domain and which require surgical means of investigation and surgical treatment. And there could be taught valuable lessons of guidance for those thrown in the narrower lines of professional life. One of the very certain and patent tendencies of such an institution would be to improve the teaching in our schools and draw to them the best talent of the country. As a rule the sons of our eminent physicians and surgeons and their students enter the medical school where their preceptors received their best lessons, they go where they are directed. If we would make Philadelphia a great center of medical and surgical education we must look to the influence of the general practitioners of the country. We must convince them that it is here that the best work is done and the best lessons taught. Then this free educational institution, blending with its work home and professional hospitalities would become a feeder for our best medical colleges. It would not draw from the schools but put better material in them, would have the healthful effect of relegating to the museums for stuffed animals the dudes who would enter the profession, and put workers within their walls. It would be auxiliary to and contribute largely to elevate the standard of our organized system of medical education. Aside from its specific educational features, to such an institution there would be a home side appealing directly to home pride.

So manifold are the details of our medical science, so rich and varied its literature that the inviting and welcoming of general practitioners and specialists visiting our city into such an institution could not be otherwise than fruitful of much good. We would get the facts of many active and rich experiences, the history of new departures from old traditions and methods. Our period has impressed its characteristics upon our current medical literature; there is little of the ancient in its lines; it has in it the research, energy and noble genius of the living. With the old we are linked only by the tested truths of science and experience. Give to them who make our literature an arena in which they can discuss the results of their work. It is only those who *never knew much* who are *tired* of learning. There is a growing, vigorous life in the American physician and surgeon no matter what his location whether country side, barracks or prairie and he is willing to work hard and make many sacrifices to keep in the front rank of his profession. He has the good practical business sense to go where the best facilities are offered him to obtain what he feels that he needs.

Joseph Price, M. D.

Preston Retreat.

AMYL NITRITE FOR AFTER-PAINS.

I am satisfied that in many cases a nice warm meal is better than any medicine. Still, I have had several cases in which the pains were exhaustingly severe, and in which I was glad to turn to nitrite of amyl. This potent drug is a very efficient controller of after-pains, and, used cautiously, I see no reason to apprehend harm from it. A neat way to use it is to saturate a piece of tissue paper with five or six drops, stuff this into a two-drachm vial, and request the patient to draw the cork and inhale the odor when she feels the pain coming on. It acts with magical celerity.—*Dr. Winterburn, in Journal of Obstetrics.*

SURGERY.

FISTULA IN ANO.

As far as diagnosticating fistula in ano is concered, that is quite an easy matter, but to tell exactly the character of the fistula we have to deal with, is quite another thing, An operation that will cure one fistula will not cure another. Therefore, no general rule will apply to these cases. There are several things to be taken into consideration in properly diagnosticating or prognosticating a case of fistula.

1. Is it a simple fistula, and has it but one channel?

2. Is it a progressive or non-progressive fistula?

3. Is it due to any special diathesis, as tubercular, syphilitic, etc.?

4. Does it exist as a disease *per se,* or is it the result (secondary) of stricture?

These are essential considerations, aud will deside the method of operating and after-treatment, and the prognosis.

To illustrate: If the case is one of simple fistula with but one channel, a single di vision of tissue, either by the knife or ligature, will effect a cure.

If it is a progressive fistula with a great discharge of pus, and a rapid breaking down of tissue, an operation *by the knife* should be advised at once. If it is non-progressive, no hurry need be had, and the patient can adapt himself to circumstances.

If the disease is due to any special diathesis, snch diathesis must be ascertained in order that the proper medical as well as surgical treatment can be afforded. Indeed, upon this is decided the question whether an operation is warranted at all.

If the fistula be secondary to a stricture of the bowel, no operation is permissible until the strictured condition is righted.

I consider, therefore, that these are points of much more significance than to determine whether the fistula be an external, internal, or complete one. It has often occurred to me that the authorities put too great stress upon this division of fistulæ. It matters very little to the surgeon who is going to operate, which variety he is going to deal with, for he is going to do pretty much the same operation in all. It is the complications that concern him, not this kind of division.—*Dr. Joseph M. Mathews, in International Journal of Surgery.*

CEREBRAL SURGERY.

Hintzig (*Berliner klin. Wochenschrift,* 1892, No. 29, p. 713) has reported the case of a mason, twenty-nine years old, who, following a blow in the right frontal region, complained of pain at the site of the injury, with impairment of memory, defective intelligence, and attacks in which paresis of the left hand appeared, while the mouth was drawn to the left; speech and deglutition were likewise slightly affected. Subsequently, vision became impaired upon the right, and then upon the left. There had been no vomiting; and there was no alteration of the pulse. The head was bent strongly forward and slightly to the left; the left shoulder drooped somewhat. There was bilatereal papillitis and concentric limitation of the visual fields. The muscles of the right side of the face were paretic. The tongue was protruded a little to the right. There was also loss of power in the left upper extremity. There was weakness of the lower extremities, slightly the greater upon the left side. Sensibility was not deranged. The knee-jerks were exaggerated, the left side in greater degree than the right. Ankle-clonus was present upon the left, and the skin-reflexes were exaggerated. In the right temporal region, in a situation corresponding with the anterior half of the origin of the temporal muscles, was a doughy tumefaction, painful upon pressure. A diagnosis of a tumor of the bone exerting pressure upon the brain in the temporal region was made, and operative procedure decided upon. A large extent of bone was removed in the right temporo-parietal region, leaveing an opening in the skull of about 3½ by 4¼ inches. The bone in places was thin; in others, thickened. A large growth was found arising from the brain and penetrating the dura. The neoplasm was carefully removed. It weighed nearly nine ounces, and proved to be a mixed sarcoma. The patient recovered absolutely from the operation, without noteworthy aggravation of his previous paretic condition.—*Medical Progress.*

THE EXTENSION OF GONORRHEA TO THE PARS POSTERIOR URETHRÆ.

After an examination of fifty cases of first infection of gonorrhea, Dr. Heisler concludes (*Med. Era*):

1. That posterior urethritis appears much earlier than is usually taught and accepted by the best writers.

His statistics show that in twenty per cent. of the cases it appeared in the first week, in thirty-four per cent. in the second week, and in fourteen per cent. in the third week after the appearance of the discharge.

2. Constitutional affections, especially syphilis, have little influence in hastening the occurrence of posterior urethritis, although the affection occurs more frequently in syphilitic subjects.

3. Occupations which necessitate long-continued exertion play an important role in expediting affections of the deep urethra.

4. The affection is equally prevalent whether injections are used or the treatment be confined to internal medication.

5. The musculus compressor urethræ has no power to prevent the transference of the infective agent to the deep urethra.

6. The gonorrheal inflammation of the anterior urethra cannot be regarded as an affection of such typical course as is asserted by the majority of authors, *i. e.*, an inflammation starting in the fossa navicularis, reaching the bulb in three weeks; then, when the acme of intensity is attained, passing over to the posterior urethra. In the great majority of the cases, this happens during the first or second week without the direct transference of the gonorrheal pus by means of catheters or sounds.

It must therefore be looked upon, not as a complication of anterior urethritis, but as a direct continuation of it.—*Med. Review.*

MEDICINE

THE POPULATION QUESTION AND SYMPHYSEOTOMY.

British obstetricians are usually averse to craniotomy or any other obstetric operation which entails the sacrifice of the child. Their scruples, however, though essentially both professional and conscientious, are based on respect for individual life rather than on any abstruse questions connected with the maintenance of the population. Those questions are of greater import across the channel. At a recent meeting of the Académie Mèdecine, M. Charpentier spoke in favor of Sigault's operation, or division of the symphysis. This operation has lately been revived, and performed largely in Naples with excellent results. M. Charpentier concludes his address by the following words to French obstetricians: "Do not abandon to the foreigner the benefits of an operation which, was first successful in our country. Try once more symphyseotomy, which, while avoiding all the evil results of embryotomy and Cæsarean section, still too frequent, will allow you to save almost certainly both the lives entrusted to your care. Remember that in this respect you hold in your hands a means of diminishing infantile mortality, an aim towards which all your efforts ought to tend, for now more than ever France has need for her children." We have already noted that Professor Morisani intends to bring the subject of symphyseotomy before the International Medical Congress at Rome in 1893. The complete revival of Cæsarean section has surprised the profession, yet the resuscitation of symphyseotomy is perhaps still more remarkable.—*Brit. Med. Jour.*

THE NATURE AND FREQUENCY OF DISEASE OF THE SPINAL CORD IN GENERAL PARALYSIS.

The spinal cord has been examined by Dr. Köberlin in twenty-three cases of general paralysis, examination being made of pieces from the cervical, dorsal and lumbar regions in each case, and the sections were stained with Wegiert's hematoxylin and with carmine. Morbid change was seen in the lateral pyramidal tracts and posterior columns. Sometimes Goll's columns alone are degenerated, at others Burdach's columns are affected, though to a less extent in most instances. Cases were observed where Goll's columns were separated by streaks of degenerated tissue from the outlying area of Burdach's. The morbid appearances comprise atrophy and degeneration of the medullated fibres with excess of connective tissue, and the presence of numerous corpora amylacea. The degeneration was found to be remarkably symmetrical both in transverse and longi-

tudinal sections. In one case syringomyelia was found but this case the author considers atypical. The cases were classified by Dr. Köberlin into: (1) Affection of the crossed pyramidal tract. (2) Affection of the posterior columns. (3) Affection of both. In one case of the first mentioned class there was a difference in weight between the cerebral hemispheres, and as the more atrophied hemisphere was opposite to the diseased lateral tract, the author is disposed to think that the pyramidal degeneration was secondary. Amongst the cases in the second class he gives reasons for considering the cord-disease as primary in some; in others the disease was probably first developed in the brain. In none of the twenty-three cases were the anterior columns or the lateral cerebellar tracts diseased.—*Dublin Journal of Medical Science.*

CONGENITAL BALDNESS AND PEMPHIGUS.

Bar (*Arch. de Tocol. et d' Obstét.*, December, 1891) exhibited before the Société Obstétricale de Paris a child born with circular patches of baldness on the hairy scalp, and a bulla of the character of pemphigus on the right hand. He suggests that the patches on the scalp might represent pemphigus at its last stage, although that disease is rarely seen after birth, except on the hands and feet. There was talipes in this case, and the pregnancy was complicated by hydramnios. No positive history of syphilis could be obtained.—*Brit. Med. Jour.*

THE CHANGES IN THE BLOOD IN DISEASE.

Sadler (*Fortschritte der Medicin,* Bd. x., 1892) reports the result of a large number of observations made at the clinic of v. Jakach, at Prague, upon the blood in various pathologic conditions. It appears that the number of red corpuscles is diminished, though, as a rule, not considerably, in the course of acute disease. In chronic disease, especially when cachexia develops, the diminution may be decided. Under the same conditions, the hæmoglobin suffers a diminution relatively greater than that of the corpuscles. To these generalizations, tuberculosis, especially if the patient be well nourished, and valvular disease of the heart, especially mitral disease, may constitute exceptions. In some cases of chlorosis, the number of red cells may for a long time be almost normal, while the proportion of hæmoglobin is considerably diminished. On the contrary, in cases of anæmia there is decided diminution both in the number of red corpuscles and in the proportion of hæmoglobin. The greatest diminution in the number of red corpuscles occurs in pernicious anæmia, though almost as profound a change may be observed in the case of anæmia following hemorrhage or resulting from other causes, such as atrophy of the glands of the stomach. In cases of pernicious anæmia, Sadler failed to find hæmoglobin in relatively greater proportion than the number of red corpuscles. In cases in which as a result of acute, profuse diarrhœa, the consistency of the blood was augmented, the number of corpuscles and the percentage of hæmoglobin were increased. A similar condition appeared in some cases of enteric fever. In untreated cases of malarial fever, the number of white corpuscles is increased. Physiologically, leukocytosis is present during digestion. Leukocytosis is also present in the puerperal state, at least for twelve days following labor. The white corpuscles are usually in excess in acute diseases attended with exudation, viz., pneumonia, pleurisy, peritonitis, pericarditis, meningitis, polyarthritis. It seems likely that there is a relation between the character of exudation and the presence or absence of leukocytosis. If leukocytosis appear in the course of enteric fever it must be considered as evidence of the existence of a complication. Leukocytosis occurred in pulmonary tuberculosis only after injections of tuberculin. Leukocytosis was present in a minority of cases of carcinoma. Four case of sarcoma present leukocytosis. There was little or no excess of leukocytosis in three cases of lymphadenitis.—*Amer. Jour. Med. Sci.*

EPILEPTIC MANIFESTATIONS RESEMBLING WRITER'S CRAMP.

Dr. Féré (*Gaz. des Hôpitaux*) speaks of a patient in whom the epileptic aura took the form of a cramp similar to that seen in writers.

The manifestation becomes general so that the attack soon resembles one of ordinary epilepsy.

As soon as the attack is passed he is able to write again, which renders the differential diagnosis easy, since this would not be the case in true writer's cramp. The bromides when given produced marked improvement.

OBSTETRICS.

HYDATIFORM MOLE.

The following is a general outline of the treatment prescribed by Dr. George A. Cragin (Boston *Med. and Surg. Jour.*): When diagnosis cannot be made these cases must be treated on general principles, and it must often happen that nothing is done until hœmorrhage, exhausting nausea and vomiting or convulsions indicate the immediate emptying of the uterus. When once the diagnosis is made the following points have important bearing on the treatment:

1. The patient is liable to repeated hæmorrhages sufficient to cause grave general disturbances, and to sudden severe hæmorrhage.
2. The closed, rigid os is almost the rule even after severe hæmorrhage.
3. The mole can be delivered without complete dilatation, and with no more loss of blood than is almost certain to follow later, when it may not be easy to interfere.
4. The uterus contracts well after being emptied, even when pains have not been present before dilatation was begun.
5. Uterine stimulants and tampons will generally have to be supplemented by the hand or curette.
6. Tampons with delay increase the danger of infection.
7. Incomplete expulsion makes hæmorrhage and sepsis liable.
8. The possibility of a thin uterine wall should be borne in mind when the curette, the hand in utero, or Crede's method of expression are used.

In the light of the above facts the proper course to be followed is clear. The uterus should be emptied as soon as possible. Just how to begin this, however, may be a question. To rely upon tampons, colpeurynter and ergot would be poor practice. The process is slow and imperfect; hæmorrhage and exhaustion greater. Yet in cases with rigid os and long, dense cervix, undoubtedly the firm vaginal tampon is a most effective means of starting up pains, and getting a soft, dilatable os.

ON THE PREVENTION OF LACERATIONS OF THE PERINÆUM PRIMIPARÆ.

The experience gained in a large midwifery practice here for some years has convinced me that the following suggestions, if thoroughly and carefully attended to, will, in the large majority of cases, allow of the passage of the fetal head with laceration of the perinæum; and this is borne out by the fact that in primiparous cases where the child was born before my arrival I have invariably observed some degree of laceration of the perineal tissue. I do not consider that the mere "supporting" of the perinæum during the birth of head is, *ipso facto*, sufficient to prevent laceration; it is but a factor in the result desired, and is beneficial by delaying any too rapid advance of the presenting part. The chief causes of rupture of the perinæum are undoubtedly—

1. Too rapid advance of the presenting part before sufficient dilatation of the parts has had time to take place.
2. Abnormal rigidity of the parts.
3. The outlet is too small or the presenting part too large.

As the presenting part reaches the perinæum the parts are expanded in all directions, and, therefore, two fingers, well anointed with antiseptic uterine lubricant (Summer's), should be used during or directly preceding the pain in order to assist dilatation by expanding the perinæum in every direction. During the intervals between the pains a sponge wrung out in warm water aseptic with carbolic acid should be applied to the perinæum, the result being some softening of the parts by relaxation of the soft parts, and in addition this application is grateful and comforting to the patient and facilitates the removal of any mucous or excreta during the passage of the presenting part. Supposing the head to present, as is more commonly the case, as labor progresses pressure should be exerted upon it in a direction to promote flexion of the chin upon the sternum, and this manœuvre not only places the head in a more favorable position for passing the perinæum but is sufficiently dilated to prevent any rupture of the same.—Charles H. Miles, L. R. C. P. Lond.—*In Hosp. Gaz.*

THE USE OF IPECACUANHA IN UTERINE INERTIA.

Drapes says this remedy in simple atony of the uterus is a powerful agent in producing uterine contraction during the first and second stages of labor.

In general, two or three doses of from ten to fifteen drops of the wine of ipacacuanha, given at intervals of ten minutes, produce in a short time marked activity of uterine action and a rapid birth. It is much better than ergot, as it does not produce tetanic contraction, but only induces normal and regular explusive efforts. —*Ex.*

GYNECOLOGY.

TECHNIQUE OF CÆSAREAN SECTION.

Chas. Jewett, M. D., in discussing this subject in the *New York Journal of Gynæcology* says, the objection to the rubber tube, in the provisional ligation of the cervix, that it is liable to injure the tonicity of the muscles, is obviated by employing a large tube with thin walls, which spreads as it is drawn taut and distributes the pressure over a large surface. It is the practice of Sanger and others after separation of the placenta and membranes to scrub the cavity with a fold of gauze. In the absence of infected fluids after peeling off the membranes the uterine cavity should be left literally untouched. The endometrium is left aseptic after removal of the secundines, and antiseptic douching or scrubbing is not only uncalled for but injurious; a septic uterus on the other hand should not be trusted to the conservative operation at all, but should be amputated. With care to prevent the entrance of much blood and liquor amnii into the abdominal cavity, the usual peritoneal toilet may be almost wholly omitted. The obvious advantage of operating with deliberate preparation before the rupture of the membranes and with the patient in full strength furnishes a strong argument for an appointed time if possible, shortly before the expected date of labor. The main conditions of success in Cæsarean section are asepsis, and the accurate suture of the uterine wound. Reasonable rapidity, however, is important, and the length of time should not exceed three-quarters of an hour if the best results are to be expected. To these conditions should be added the early use of saline catharsis after operation. The writer's experience, not alone in these cases, but a somewhat extensive one in analogous conditions, leads him to place a high value on early resort to peritoneal drainage by the intestines.

HERNIA OF ABDOMINAL CICATRIX AFTER LAPAROTOMY.

Goullioud (*Arch. de Tocol. et de Gynec.*, July and August, 1892) compares the ventral hernia of pregnancy and abdominal tumor with the troublesome hernia of the cicatrix after ovariotomy and other forms of abdominal section. In the first form, common amongst multiparæ, the linea alba is simply relaxed through excessive distension of the tissues which compose it. The aponeurotic layer of the abdominal walls remains entire, though thin, like the skin, and peritoneum, from stretching. In hernia after operation, the protrusion is due to non-union of the aponeurotic layer of the linea alba. Hence Gouillioud maintains that the aponeurotic layer of the abdominal incision should always be united by a special line of sutures. Three radical operations for the cure of hernia of the cicatrix are practised. Simon inverts all three layers and, making raw surfaces on the skin, unites them by suture. Maydl resects the entire sac and applies a special line of suture to each layer. In a third method the skin is resected, the other layers inverted, and their folded edges sutured, and lastly the edges of the skin wound united by a separate line of suture. This operation, advocated by Chrobak, is more suited for ventral herniæ not due to operation. It has the advantage of avoiding the opening of the abdominal cavity. Complete resection, however is as a rule preferable in hernia after ovariotomy, etc. The serous layer of the sac usually possesses secondary pouches, bands and omental adhesions. Their removal is clearly an advantage. Guillioud warns the surgeons of the difficulties of resection. The three layers are fused by tissue more or less dense. Hence free excision of the sac renders the operation less irksome, and is more advisable to the patient; the further the surgeon cuts from the limits of the cicatrix the easier will be the separation of the layers. When separated, after long and careful dissec-

tion, they must be sutured separately. The fibrous ring forming the neck of the sac often gives great trouble. The operation of resection is most likely to succeed when the recti are not overstretched; when, in fact, they still contract firmly. A perfect union of the aponeurotic layer is, of course, essential. Without such union the secondary operation will be followed by a yet larger hernial protrusion. —*British Medical Journal.*

A DERMOID CYST CONTAINING A HEART.

At the October meeting of the Academy of Medicine, Dr. J. A. Johnstone related (*Cincinnati Lancet-Clinic*, October 15) a case of this nature, exhibiting the specimen. He said:

The object in reporting this case is to show something very unique, and something I have never found before in a dermoid cyst—the interior of this gives you a very well-formed attempt at the formation of a heart. My second reason for making the report is to show what nature will do towards saving the life of patients who have had accidents. This tumor existed for several years. The patient was an Irish girl aged about twenty-five years, and gave a very indefinite history. Along in July last she had an attack of pain in the abdomen, and she said it seemed as though she was going to die right away, but it all passed off. However, when I came to do the operation, the cause of the pain was very apparent. The axis had been rotated upon itself almost twice and a half. The axis being the round ligament, this had been enough to excite a very marked peritonitis. The tumor was adherent, tremendously large vessels passing into it. The tumor was slate-colored at the time of the operation.

This attempt at the formation of a heart is something of which I never knew. There is a case recorded where an eye was pretty well formed, the cornea being well shown. Gray matter of the brain has been found, and, in fact, all portions of the hypoblast and mesoblast have been found. I am led to believe that the simple variations of the cyst is the fault of the Graafian follicle, but the formation of the dermoid is due to the ovum, which is retained, and in some way or other produces this formation.

The patient recovered.

HYSTERECTOMY.

Mr. Lawson Tait contributed to the Obstetrical Society of London (*N. Y. Jour. of Gyn. and Obst.*) notes of two cases of hysterectomy. The first patient was fifty-two years of age; had ceased to menstruate two years ago, and during the two months before Mr. Tait saw her the tumor had grown more rapidly. It reached up to the sternum and pseudo-fluctuation was distinctly present. When the abdomen was opened the tumor was found to be a myoma, and fluctuation was so distinct that a trocar was plunged in, and six pints of fluid removed. The tumor (which weighed about five pounds) was clamped and removed. The patient made an uninterrupted recovery. The second case was that of a woman, aged forty-two, who had had three children, all the labors being normal. When thirty-seven years old she began to lose profusely, and then noticed a substance in the lower abdomen. A large, multinodular myoma, reaching above the umbilicus, was found on admission, and the appendages were removed May 13, 1888. She reported herself July 26, 1890. Menstruation had not recurred, and she felt perfectly well. The tumor was found to have nearly disappeared. Later on metrorrhagia recurred; the uterus was explored for polypi, but none were found, and the endometrium was curetted with temporary relief. The discharge came on again, and the tumor had again increased in size; so on October 12, 1891, hysterectomy was performed. The old multinodular myoma was hardly to be seen, but a large, independent growth of a soft, endematous character had grown to the size of the original tumor. The patient made an uninterrupted recovery. The case was a unique example of a soft myoma springing up after a multinodular one had been removed; and Mr. Tait considered that whilst the latter variety of myoma was a disease of menstrual life, the former was not so.—*Med. Review.*

Laparotomy for the treatment of tubercular peritonitis gives very flattering results. The ascitic form gives a mortality of 20 per cent., permanently cured at the end of a year 35 per cent. of cases. The dry, fibrous type of the disease gives a mortality of 10 per cent., and of those

who survived the operation 50 per cent. were living and well at the end of the year. The purulent ulcerous type of peritonitis gives 40 per cent. of mortality and about 25 per cent. remain permanently well. In tubercular peritonitis of genital origin, about 25 per cent. remain permanently well.—*Ex.*

VAGINAL HYSTERECTOMY IN PELVIC SUPPURATION.

At a recent meeting of the Paris Surgical Society. Dr. Terrillon spoke favorably of this extreme measure. He has operated on four cases of old-standing pelvic suppuration with hectic exacerbations and rectal and vagnal fistulæ.

The first patient had been ailing for two years subsequent to a miscarriage; parametric infiltration extended up as high as the navel, and the uterus was firmly fixed in the inflammatory deposit. Abdominal section proved useless; the omentum could not be detached, and the intestines were so firmly adherent that no attempt was made to liberate them. The uterus was at once extirpated from the vaginal side. On the twenty-eighth day serous symptoms developed—owing to retention of pus behind the vaginal fistula cicatrix. The fever ceased as soon as an exit was made for the pus; but a vagina fistula remained.

In the second case—similar to the first—abdominal section was found impracticable, and vaginal hysterectomy was performed eight days later, with the result of effecting a complete cure.

In the third case the patient had been ill for nine years, and was suffering from a lichenous eruption which had been attributed to septicæmia; albuminuria, vomiting and fever were present. Vaginal hysterectomy proved very troublesome, and considerable shock followed. Nevertheless, the patient recovered, and the annoying eruption disappeared.

The fourth patient had peen ill for twelve years, and had suffered from severe continuous pain and fever since two months. Vaginal hysterectomy was preformed on the left side; the vagina cicatrized nicely, but a rectal fistula remained.

The last mentioned case is sufficient to show—according to the author—that the operation does not always bring about a radical cure; the first two cases, on the other hand, demonstrated that vaginal hysterectomy may succeed after abdominal section has proved of no avail. Although the operation appears especially desirable in cases where there is a well-incysted abscess, Dr. Terrillon considers it required in cases of old extensive and ill-defined suppurative processes with fistula, adhesions, and parametric infiltration of the parieties.—*Merck's Bulletin.*

HYGIENE.

THE PATHOLOGICAL EFFECTS OF HEAT.

Some interesting observations have been recorded by Drs. Coplin, Bevan, and Sommer on the effects of heat as manifested in workmen in a sugar refinery in Philadelphia. During the very hot weather the number of men on duty was 800 during the day, and 500 during the night, and in the course of eight days 213 of these came under treatment. The most common and troublesome symptom complained of was cramp in the epigastrium, with not infrequently similar pain in the calves, sometimes in the back and hypogastrium, less commonly in the thighs and upper extremities. Other symptoms were difficulty of respiration, pain in the splenic or hepatic regions, headache in nearly all cases, nausea, rarely vomiting, agitation, pale skin (if moist, cold, and clammy). In a few cases diarrhœa was present, in the majority constipation preceded the attack. Later delirium, sometimes active, came on, with convulsive movements, ending, in fatal cases, in coma. The pulse was irregular, the urine scanty and high-colored. Pain in the cervical region, and generally in the back, was complained of; the patient may be conscious of the high temperature, but as a rule he felt cold when brought out of the intense heat. There was great thirst. The pathology of the cases was obscure, but the symptoms pointed to a large accumulation of blood in the portal system. The area of hepatic dullness was largely increased, as a rule, in proportion to the intensity of the attack, and the same increase could be noticed in regard to the spleen. Curiously enough, the rectal temperature was two to five degrees higher than the oral. With regard to the temperatures of the men who complained, in two the temperature was 108° F.; one of these died, the temperature reaching 110° F. In twenty-eight the

temperature was 105° F., in fifty between 102° F. and 105° F. In the remaining 133, the temperature in sixty-two was above 101° F.; in forty-nine between 100° F. and 101° F.; in eight between 99° F. and 100° F.; in eleven between 97° F. and 99° F.; in one, 96° F.; and in two between 95° F. and 96° F. There were more cases of illness in the rooms where the atmosphere was humid than in those where it was drier, and there was no evidence that men who drank beer freely suffered as much as those who drank little or none at all, while those who drank largely of water were extremely prone to suffer.—*Med. Press.*

DIETETIC TREATMENT OF TYPHOID FEVER.

In a recent article on this subject by Beatty Wallace, he claims that milk is the safest and best diet.

It may be diluted with soda water or lime water and may be peptonized.

Should diarrhœa exist, the milk may be boiled.

If the patient can take milk alone it is the best food during the entire illness.

Beef tea may also be given, and is a useful addition to milk.

Farinaceous foods he considers objectionable because of the flatulence following their use, and the liability of a fresh outburst of fever.

Beaten up eggs should be avoided unless milk cannot be taken.

In any case two or three pints of liquid food will be found sufficient for an adult each day.—*Epitome of Medicine.*

NEWS AND MISCELLANY.

IDIOPATHIC.

This a word used very frequently by the profession, but it is doubtful whether it is a proper term. If by the term we mean a disease without an underlying cause, it certainly has no place in medical nomenclature. When we cannot say what ails a patient it is better to say that we do not know than to use the word idiopathic. "Idiopathic" pluritis and "idiopathic" pericarditis are slaying hundreds of people to-day. "Idiopathic" peritonitis slew thousands of women before it was demonstrated that peritonitis never existed without underlying cause.—*Ex.*

USED WITH EFFECT.

A practitioner in Chicago told me that in a labor case, after giving to the husband, who was acting as nurse, the usual order, "Let me know if everything is not right," he left. In the course of a few days, the nurse called on the doctor to ask if the foul odor could not be stopped. He said, "Did you use the syringe I gave you?" "Oh! yes, doctor, and although it does not affect the odor, it moves the bowels finely." Another case, which was under the care of a brother practitioner in the town in which I live: The doctor took the Davidson syringe, showed the intelligent (?) nurse how to use it in a basin of water, and left happy. Next day, not liking the appearance of the patient, he inquired, "Did you use the syringe?" "Yes, doctor, but the mixture you ordered was no sooner down, than it all came up again, and everything that had been eaten for a week." It is a fact that the nurse forced a pint of soap-suds down the patient's throat, by means of the syringe.—Dr. Caldwell, *Southern Med. Record.*

A NATIONAL BACTERIOLOGICAL INSTITUTE.

This is advocated by the *International Journal of Surgery* which says, *inter alia*, that a central laboratory should be established by the Government equipped with all the modern appliances for the experimental study of contagia, with experiment stations, and with a staff large enough to cover the whole ground and paid well enough to secure the most efficient services. Finally, and above all, such an institution must be entirely free from the taint of politics. The Imperial "Gesundheitsamt," at Berlin, which is conducted by Professor Koch, may well serve as a model of what a modern civilized government should do in this direction. There are, to be sure, a number of laboratories either private or connected with the medical schools, but the workers there are almost invariably men who depend upon active practice or teaching for a livelihood, and who pursue bacteriological research as amateurs. The entire time and all the energies of the best men are requisite for this work. Only the Government can guarantee these conditions.

Only the Government has the force at

hand to investigate contagious diseases; and on the Government, representing the entire community, the duty devolves. Systematic and careful work in the investigation of human and animal plagues; work done on the largest scale and with the facilities that only the government can supply; this is far more important to the sixty millions of this community than petty trade and boundary disputes.—*Salus supremum jus!—Med. Review.*

At the recent meeting of the American Orthopedic Association held in the City of New York, September 20, 21 and 22, 1892, the following officers were elected to serve for the ensuing year: President, Dr. A. J. Steele, St. Louis; Vice-Presidents, Dr. Samuel Ketch, New York; Dr. Arthur J. Gillette, St. Paul; Treasurer, Dr. A. B. Judson, New York; Secretary, Dr. John Ridlon, 34 Washington St., Chicago. The next annual meeting will be held in St. Louis, the third week in September, 1893.

ELECTRICITY AND FILLED TEETH.

George E. Zinn (*Dental Review*) says: Some patients are of such a bodily temperament, as to act like Leyden jars or storage batteries. The electricity may be generated by the friction of the hands on a dry substance, such as cloth. It is not evenly distributed through the body, and whenever a metal instrument comes in comes in contact with the tooth, there results an electric current for the equalizing of the electricity. This accounts for the pain sometimes experienced from touching one's own filled tooth.

Some dentists are likewise living storage batteries. They have their offices carpeted and the friction of their feet generates electricity, they approach the patient to examine his teeth, touch a filled one with an instrument and the patient experiences a sharp pain. This is caused by the passing of electricity from his body through the instrument to the tooth and the body of the patient by means of the connection made with the tooth. It is a well known fact that bodies have different capacities for electricity, that when two bodies unequally charged in proportion to their capacities come in contact, a current passes from the one to the other, equalizing the electricity of the two bodies, and it is so with regard to the patient and dentist. This explanation seems to me clear. I have heard it attributed to the "Electrical Condition" but not explained, consequently I have told my patients it was due to certain "Electrical Conditions," but never had a rational understanding of it. They, of course, would go home half believing it was so, or fully believing that it was the fault of the filling or of my work.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY FROM OCTOBER 16, 1892, TO OCTOBER 22, 1892.

First Lieutenant George D. DeShon, Assistant Surgeon, U. S. Army, is relieved from duty at Columbus Barracks, Ohio, and will report in person to the commanding officer, Fort D. A. Russell, Wyoming.

So much of S. O. 230, as relates to change of station of Captain Eugene L. Swift, Assistant Surgeon, is suspended until further orders, and he is granted leave of absence for one month, on account of sickness, with permission to apply for an extension of one month.

Captain Edward R. Morris, Assistant Surgeon, U. S. Army, is relieved from duty at Fort Custer, Montana, and will report in person for duty to the commanding officer, Fort Warren, Mass., relieving Captain Peter R. Egan, Assistant Surgeon, U. S. Army.

Captain Egan on being relieved by Captain Morris, will report in person to the commanding officer, Fort Custer, Montana, for duty at that post.

First Lieutenant Allen M. Smith, Assistant Surgeon, U. S. Army, is relieved from further duty at Fort Assinniboine, Montana, and assigned to duty at Fort Custer, Montana, where he had already been ordered to temporary duty.

Major John C. J. Happersett, Surgeon, U. S. Army, is relieved from duty at Fort Custer, Montana, and will report in person to the commanding officer, Fort Keogh, Montana, for duty at that post, relieving Major Philip F. Harvey, Surgeon.

Major Harvey on being relieved from duty by Major Happersett, will report to West Point, N. Y., and report in person to the Superintendent of the U. S. Military Academy, for duty at that post relieving Major Henry McElderry, Surgeon.

Major McElderry, on being relieved by Major Harvey, will repair to Omaha, Nebraska. and report in person to the commanding general Dept. Platte, for duty as attending surgeon.

First Lieutenant William E. Purviance, Assistant Surgeon, U. S. Army, is relieved from duty at Jefferson Barracks, Missouri, and will report in person to the commanding officer, Fort Sherman, Idaho, for duty at that post, relieving Captain William W. Gray, Asst. Surgeon.

Captain Gray on being relieved by Lieutenant Purviance will report in person to the command-

ing officer, Fort Schuyler, New York, for duty at that post.

The leave of absence granted First Lieutenant Samuel R. Dunlop, Assistant Surgeon, is extended one month.

Lieutenant Colonel Charles R. Greenleaf, Deputy Surgeon General, is appointed member of a board of officers, to meet at Helena, Montana, on the first day of November, 1892, or as soon thereafter as practicable, for the purpose of selecting a site for a military post at that place, as provided for under an Act of Congress approved, May 12, 1892, entitled "An Act to establish a military post at or near the city of Helena, in Lewis and Clarke County in the state of Montana."

First Lieutenant Allen M. Smith, Assistant Surgeon, U. S. Army, is relieved from further duty at Fort Yellowstone, Wyoming, and will proceed to Fort Custer, Montana, and report to the commanding officer of that post for temporary duty.

Leave of absence for one month, to take effect upon his relief from duty at Fort Columbus, N. Y., is granted Major Johnson V. D. Middleton, Surgeon, U. S. Army.

OFFICIAL LIST OF THE CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE U. S. MARINE HOSPITAL SERVICE FOR THE THREE WEEKS ENDED OCTOBER 15, 1892.

Purviance, George, Surgeon. Granted leave of absence for seven days, Oct. 12, 1892.

Banks, C. E , Passed Asst. Surgeon. To rejoin station at Portland, Maine, Oct. 14, 1892.

Devan, S. C., Passed Asst. Surgeon. Ordered to Washington D. C., for special duty, Sept. 29, 1892.

Kallock, P. C., Passed Asst. Surgeon. To rejoin station at Boston, Mass., Oct. 14, 1892.

Wasdin, Eugene, Passed Asst. Surgeon. To rejoin station at Charleston, S. C., Oct. 3, 1892.

McIntosh, W. P., Passed Asst. Surgeon. To proceed to Buffalo, N. Y., for temporary duty, Sept. 25, 1892. To proceed to Ellis Island for temporary duty, Sept. 30, 1892. To report in person to the Supervising Surgeon General, Oct. 8, 1892. To rejoin station at New Orleans, La. Oct. 10, 1892.

Pettus, W. J., Passed Asst. Surgeon. To proceed to New York, N. Y., for temporary duty, Sept. 25, 1892.

Magruder, T. M., Passed Asst. Surgeon. To proceed to Tacoma, Wash., for special duty, Oct. 7, 1892.

Cobb, J. O., Passed Asst. Surgeon. To rejoin station at Detroit, Mich., Oct. 7, 1892.

Stoner, J. B., Passed Asst. Surgeon. To rejoin station at Pittsburgh, Pa., Oct. 3, 1892. Granted leave of absence for seven days, Oct. 4, 1892.

Rosenan, M. J., Asst. Surgeon. Relieved from duty at Cape Charles Quarantine, Oct. 11, 1892. Granted leave of absence for thirty days, Oct. 13, 1892.

Cofer, S. E , Asst. Surgeon. Granted leave of absence for three months on account of sickness, Oct. 15, 1892.

Gardner, C. H., Asst. Surgeon. To report to the Medical Officer in Command, San Francisco, Cal., for duty, Oct. 12, 1892.

GLYCOZONE.

PREVENTS FERMENTATION OF FOOD IN THE STOMACH.
MOST POWERFUL REMEDY FOR HEALING PURPOSES. CURES:
DYSPEPSIA, GASTRITIS, ULCER OF THE STOMACH, HEART-BURN.
Send for free book of 80 pages giving articles by contributors to medical literature.
PHYSICIANS WILLING TO PAY EXPRESS CHARGES WILL RECEIVE FREE SAMPLE ON APPLICATION.
Glycozone is sold only in 4 ounce, 8 ounce, and 16 ounce bottles. Never sold in bulk.
PREPARED ONLY BY
Charles Marchand

Improvement the Order of the Age

Simplicity not its only recommendation.

Most compact. Best made.

Its merits and durability warrant the price asked.

Thoroughly tested.

Has NO shift-key.

15 IMPROVEMENTS · OVER OTHER MAKES.

Permanent and perfect alignment.

Received the endorsement of the U. S. Government.

Easiest-running Typewriter known.

Manifolding powers unexcelled by any other.

Its merits are plainly seen.

Excellent material and workmanship.

Recommended by users.

The Smith Premier Typewriter Co.,

H. B FEBIGER, Manager. 335 Chestnut Street, Phila., Pa.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL & NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

PETERSBURGH, INDIANA.

I.

THE GALL-STONE DIAGNOSIS.

Pelvic inflammatory conditions simulate so many and so various forms of disease, that the general practitioner may well be pardoned who fails to attribute to their proper cause the myriad symptoms arising from even the grossest pelvic lesions. One of the most striking and misleading symptoms due to well-marked disease of the appendages, is a severe, agonizing and sickening pain, radiating across the epigastrium, and locating with great intensity in the region of the gall-bladder. The patient sits up in bed, leans forward, grasps the region of the gall-bladder and stomach with both hands, and retches as though she would throw up her immortal soul. What makes this symptom more misleading, is the mild jaundice which often follows, with coated tongue, loss of appetite, and marked tenderness on pressure over the locality of the gall-bladder. When the practitioner, for the first time sees the patient in one of these paroxysms, his attention is so forcibly called to the liver as the *fons et origo* of the trouble, that he is very prone to stop at that organ, and interrogate no other anatomical structure for information. A diagnosis of gall-stone colic is promptly made, and, knowing the futility of medicine for permanent relief or curative action on such a pathological condition, he confidently reaches for his hypodermic syringe and promises immediate relief. Here another surprise awaits him. Heretofore various attacks of abdominal pain, such as spasmodic colic or cholera morbus, or simple gastralgia due to acute indigestion, have, in his hands. yielded promptly to a single injection of an eighth or a sixteenth of a grain of morphia; but in this case the patient receives from one-half to three-fourths, or even a grain, ere she can be quieted, and even then her rest is only fitful, and the morphia must be repeated every 4 or 5 hours, often for days, before the attack subsides, which happens whenever the pelvic congestion, due to a menstrual molimen, passes away under the influence of the pain-enforced rest, the lightly injested food, a consequence of the anorexia of disease, and the free purgation inaugurated to overcome the constipation resulting from the large quantity of morphia necessary to subdue the imaginary gall-stone cramps.

This is a symptom which is, in my experience, most often found associated with a large, adherent tubo-ovarian cyst of one side, filled with sanguino-purulent material and lying high up, while the tube of the other side is highly inflamed and contains a small collection of pus, with an adherent, atrophied and cirrhotic ovary at its fimbriated and occluded extremity. There are certain precautions to be observed when we are called to such a case that will always prevent us from falling into error. First, when called to see a woman suffering from any severe or obscure form of abdominal pain, suspect the pelvis, and proceed to interrogate it. In these cases where gall-stones are suspected, if the disease is located within the pelvis, a great many other symptoms may be elicited by judicious questioning, which ought to pave the way for a digital examination. The pains and nausea will be found to precede, and become coexistent with, menstruation, which is very irregular as well as painful. A profuse, purulent and offensive leucorrhœa is a constant and disgusting accompaniment. The stomach is irritable and delicate at all

times, while the appetite is capricious. There is marked discomfort, often severe pain upon motion. Going up or down stairs, or running a sewing-machine will frequently bring on an attack of pain or greatly prolong the menstrual flow. Riding in a jolt-wagon, or in a buggy over rough roads, can not be done without great suffering. If the disease is on the left side, there is marked pain in the left iliac region when the bowels move, and this is much increased when defecation follows upon a previous condition of constipation. The bladder may be irritable, compelling the patient to micturate with great frequency and straining, and only a small quantity of urine can be voided at a time. Sexual intercourse is always painful, very seldom gratifying, never fertile, and often utterly impossible. There is frequently a history of previous abortion or abortions, and not seldom a gonorrhœa can be traced to the husband. While we need not be surprised to find that at some previous confinement she had a "bad getting up," or a "very tender belly with fever for a long time and has never been stout since."

Should several or all of these facts be elicited, a careful bimanual examination should follow. If there is leucorrhœa, we will find the size, position, outline, consistence and patulousness of the uterus all to be considered. We shall not be disappointed to find a soft and patulous os, an enlarged and softened body and fundus, with the uterus in a state of chronic retroversion, and fixed in that position by firm adhesions. The fundus may likewise be pushed to that side opposite the disease, thus lying in an oblique position. On account of the contracture of the adhesions, the uterus may be partially prolapsed. The vault on one or both sides may be found full and tender, and, bimanually, (though not always,) a fluctuating tumor the size of a small lemon may be identified on one or both sides, while pushing the uterus toward the fullest and tenderest side with the finger on the cervix, provokes loud complaint from the patient. To elicit fluctuation, or to determine the consistence of any growth filling the vault, is best done by placing one finger in the vagina, pushing it deeply up against the lateral vault, and then placing the other hand on the abdomen, by making deep pressure downward, backward and inward the growth is pushed against the finger in the vault. Then by a gentle palpation with the outside hand held firmly, fluctuation can be recognized by the finger tip held against the vaginal roof. Given such a case, and having satisfied ourselves that pelvic disease exists beyond a doubt, the next question is, what shall we do to relieve our patient? There are two courses open to us, one of which is temporary, palliative, and only to be used to gain time for the second or radical and curative surgical treatment. Saline cathartics, such as mag. sulph., given in small doses, say a teaspoonful every hour till six or eight doses are taken, will afford the quickest and most enduring relief short of any but surgical methods. Hot douches, the application of dry or moist heat over the abdomen, are good measures for the immediate palliation of pain, and to tide the sufferer over the acute attack in order that time may be gained to prepare for the necessary surgical measures that alone can bring permanent relief. Nothing short of a section, with removal of the morbid structures, will prove in the least curative, and the less delay there is in resorting to surgery, the brighter the prognosis, both as regards the final completeness of cure and the length of time necessary for the acquired reflexes to forget their old habits.

The relief which promptly follows a thorough removal of offending organs by abdominal section in these cases, is often as gratifying to the medical attendant as it is surprising to the patient and her friends. The measure of comfort and freedom from pain and suffering that follows at once the necessary surgical work, is most often in an inverse ratio to the delay in the inauguration of such measures. Time always gives an opportunity for tubal leakage, with its resulting circumscribed peritonitis; increases the strength and multiplies the number and extent of adhesions; gives rise to distortion, displacement and degeneration of structures, producing constriction of nerve-trunks and aberration of functions; abolishes normal action in glandular secretion, or excretion favoring excess of the one, paucity of the other, thus converting local into somatic disease by the mechanical effects of pressure, obstruction and displacement, or by the more insidious, but no less baneful effects of long continued irritation on

nerve-ends, results in morbid reflexes, which, though remote and obscure, are none the less destructive to comfort or elusive to diagnosis.

The following illustrates the difficulties of diagnosis met with in such cases as I have attempted in this article to describe:

Was called late one evening to see Mrs. V., who, the attending physician stated, was suffering from an attack of gall-stones. Had been under his care for several months, with recurring attacks of pain and vomiting. Found her drawn up in bed, hands pressed strongly against the right hypochondrium and stomach, and at intervals straining and vomiting with much effort and in great agony. Tongue coated, bowels constipated, temperature elevated, bladder irritable, and she complained of a sickening pain radiating over region pressed on by hands, and especially at a spot marking the location of the gall-bladder. This region was markedly tender on pressure. There was slight jaundice, complete anorexia, puffy skin, swollen eye lids and intense headache. She had just closed a menstrual period. Personal history showed last child 9 years old, miscarriage six years previous, puerperal peritonitis, specific infection by previous husband, marked irregularity of menstruation ever since, great suffering at times, general invalidism. Sexual intercourse absolutely repulsive on account of pain. I suggested a pelvic examination which was acceded to. Examination showed uterus slightly enlarged, retroverted, partially prolapsed, firmly bound down by adhesions, os soft and patulous, profuse leucorrhœa, left vault full, elastic, very tender to the touch, right vault less so, right obliquity of uterus. Pushing uterus toward the left, caused great pain which was referred to locality complained of when first seen, and which increased the efforts to vomit.

Diagnosis: Tubo-ovarian disease. Section suggested as the only means of cure. Another physician having been called into the case, and having carefully examined her, he was inclined to favor the idea of gall-stones. Wishing to be certain, and having a great deal of respect for his opinion, knowing him to be careful and conscientious, I asked one of the leading Western abdominal surgeons to examine her. He at once confirmed my diagnosis, and endorsed my advice as to a section. After preparing her for the operation, I removed a large tubo-ovarian cyst from the left side, where I found it completely buried in adhesions. It was filled with blood and pus. The tube and ovary on the right were both diseased. The tube dark, highly inflamed, its fimbrated extremity occluded and adherent to the ovary, which was small and cirrhotic. The tube contained a small quantity of pus. Both tube and ovary were bound to omentum and pelvic peritoneum by moderately firm adhesions. She made an uneventful recovery, and has been able to go about and enjoy life ever since the fourth week after the operation. She has continued to grow stronger, and has had no more of her old attacks of pain, although a year has intervened since she underwent the operation.

LIVER INDIGESTION.

By J. D. MYERS, M. D.,
HUNTINGTON, W. VA.

Recognizing the fact that the tendency of the age is to run after new ideas, frequently losing sight of the old well established landmarks, I wish to recall to the attention of the profession some old but vital truths. I have discovered no new bacilli or bacteria, but have unearthed some important facts which I beg leave to present.

It is not my intention in this paper to make mention of any of the organic diseases or accidents which may affect the liver, but only that functional trouble known as biliousness, or better, liver indigestion, with its sequelæ. In order to fully understand our subject it will be well to say a few words as to the liver and its functions, although it may seem like repeating an old tale. The liver is the largest, and we may say the most important gland in the body, its size and the importance of its functions being considered. In the mature fœtus, it holds one-fourth or more of the entire volume of blood and is larger than both lungs. At birth the weight of the liver is in proportion to the whole body as one to twenty-eight; in infancy one to twenty, at puberty one to thirty, in adult one to thirty-five, in middle life one to forty, and in old age one to forty-five. These figures give us a fair idea of the important part it plays in

the economy of our system. Up to about the year 1860, the liver was really a great "terra incognita" whose principal office seemed to be to eliminate bile which was "excrementitious" and was the natural purgative; although as far back as Galen, certain maladies when the urine was altered in appearance and reaction, were rightfully attributed to the liver and not the kidneys. Dr. Kirke, in his Physiology published in 1860, although he had made great advances in the analysis of the composition of bile, and recognized in it the presence of glycocholic and taurocholic acids in union with soda, threw no light upon their origin.

Not till 1874 was the three-fold function of the liver demonstrated, which is as follows:

1st. "The formation of glycogen which contributes to the maintenance of animal heat, to the nutrition of the blood and tissues, and the development of white blood corpuscles.

2d. The destructive metamorphosis of albuminoid matter and the formation of urea and other nitrogenous products which are subsequently eliminated by the kidneys, these chemical inter-changes also contributing to the development of animal heat.

3d. The secretion of bile, the greater part of which is reabsorbed, assisting in the assimilation of fats and peptones, and probably in those chemical changes which go on in the liver and portal circulation; while part is excrementitious and in passing along the bowel stimulates peristalsis and arrests decomposition."

This summary brings us well up to our time, and gives in condensed form the results of years of patient investigation. We recognize then, that the liver is the storehouse for our fuel food in the form of glycogen, which is converted into sugar by a ferment, in the liver itself as the needs of the system demand. Hence, we can readily see how any derangement in this glycogenic function of the liver will give us diabetes mellitus. The disorders of the liver, are, however, mainly connected with its second function, that is, the metabolism of albuminoids; we easily recognize its action in the destruction of waste and excessive albuminoids; we know that urea is formed by the liver and not the kidneys, we find that lithiasis is primarily a derangement of the liver, and that it is waste matter in the blood which after a time produces structural changes in the kidneys. We can also see that when oxidation is imperfect, it is the nitrogenous matters that suffer.

What we now wish to reach is the further elaboration of the proteid matters which have been converted into peptones in the stomach. There is no doubt that a further elaboration of peptones goes on in the liver and disturbance of this organ leads to mal-nutrition. It seems just here that the liver has another function, that of arresting certain matters whose presence in the blood would be noxious and allowing nutritive matters to pass on.

It has been demonstrated by experiment that peptones when taken into the general circulation are depressants.

Peptones injected into the veins in small quantities prevent the coagulation of the blood, and in larger quantities produce a depression of the circulation, a soporific condition, complete arrest of secretion by the kidneys, convulsions and death. Thus we see the normal products of digestion are poisons, and if they reach the general circulation in large quantities will produce alarming and dangerous symptoms, as a consequence then, of a disturbance in the workings of the liver, we have not only a badly nourished organism, but one actually poisoned by the presence of these products of digestion. We have both anemia and toxæmia. Is it any wonder then, that nervous depression and irritability always accompany this form of indigestion? We find then, to sum up that there is in the healthy liver both a digestive and a filtering process. We may therefore suffer with that form of indigestion called "biliousness," either from imperfect digestion of the food, or imperfect filtration. In either case the system is ill fed and also poisoned by the absence of certain constituents and the presence of others. We have all seen an acute bilious attack follow free indulgence in rich food, especially in children. Even a small piece of cake may be sufficient to upset the digestion followed by nausea, headache, sometimes vomiting (this gives relief) and sometimes purging. Now these are the facts of the case, but what is the cause? The mother will tell you, "it was the sweets and rich cake; anything with too much sugar or butter always upsets that child." The doctor nods

his head and says, "that child must be watched as to its eating and sweets and fatty food must be interdicted." Now this explanation is wrong, for it is the metabolism of albuminoids in the liver which causes this disturbance, and it is the second function of the liver which is involved, that is, the oxidation of waste and nitrogenized matter. The attack is not due so much to the quality as the quantity of the food ingested and is an old-fashioned subject. More food of the kind has been taken than can be assimilated and the surplus must be gotten rid of in some way. Unless removed by vomiting or purging it must be done by oxidation and we are all familiar with the sudden sharp rise of temperature which accompanies acute indigestion. This is simply a bon-fire kindled by the liver to clear out its overloaded store rooms. A mercurial and a saline and the attack is usually over, although the liver may remain irritable, bringing on a condition commonly called "bilious fever." Now this attack was brought on by eating rich food and was ascribed to the butter and sugar, but it was the metabolism of the albuminoids which caused it. The excess of food caused the excess of bile with the consequent general disturbance. The easily oxidizable hydrocarbons were burnt, leaving the albuminoids to be gotten rid of in any way possible. It is therefore the prevention rather than the treatment of such cases that demands our attention. The capacity and strength of each individual liver should be gauged as accurately as possible. Avoid excess in eating, but don't lay too much stress upon any form of food, for so long as the sugar and fat are alone held responsible, so long will the patient be wrongly fed. Albuminoids will be allowed and hydrocarbons interdicted, and the tendency to biliousness directly fostered.

'Tis said, the happiest man in the world is the one who does not know he has a liver, and this reminds me of a trouble we occasionally meet with, but which is not generally recognized. A congenitally inefficient liver. This requires constant watchfulness and care. As it is not up to the work of a normal liver we must reduce the quantity of food to what it can dispose of. However, the largest eaters are not the healthiest or strongest. 'Tis the amount assimulated, and not that ingested that tells the tale. We will now look briefly at two forms of liver disorder. Biliousness proper, in which the bile acids make the disturbance, and "lithiasis" in which case owing to a derangement of the second function, lithic acid has been formed by the liver. Biliousness is the form of trouble found in persons of "bilious temperament," as it is expressed. They are usually of a dark complexion, with black or dark brown hair, dark eyes with a yellowish tinge of the conjunctiva. They may be active or sluggish, but are possessed of a devil. Appetite capricious, bowels irregular, usually constipated, but have diarrhœa when an attack is passing off. Have frequent and persistent headache, are nervous and irritable and are usually gloomy and morose. The term of Greek derivation, we have adopted for this condition, indicates precisely the cause of this mental depression, "melancholia," which means "black bile." The tongue is usually furred, of a yellowish or brown color and there is a bad taste in the mouth. Sometimes, however; the tongue is clean although the bitter taste is present. Disorder of the bowels is common, there is torpor often accompanied by flatulency, often acidity of the intestines is present, accompanied by a headache peculiarly its own. The stools are pale, more especially so when there are lithiates in the urine, and are offensive. Neuralgia, severe headaches, dimness of vision and vertigo are generally present. All these phenomena are those of excess of bile poisoning the whole system, but chiefly disturbing the digestive tract. The influence of this state upon the animal spirits has been long recognized, and is undoubtedly due to the action of the brain and the liver, and to the lowered blood pressure. Mention has already been made of the depression caused by the presence of albuminoids in the blood vessels. While there may be a great deal of "pure cussedness" in the individual, still irritability of temper is a prominent and almost constant companion of the liver trouble. The late Thos. Carlyle, who "had been there," voiced it thus: "The accursed hag, dyspepsia, had got me butted and bridled, and was ever striving to make my living day a thing of ghastly nightmares. I resisted what I could, never did yield or surrender to her, but she kept my heart right heavy, my battle being sore and hopeless." There is really

very little difference in degree of hurtfulness, between the bile acids and the lithiates. Both are powerful for evil. We must now, however, look at the remoter results of this perverted liver action and its effects upon other organs. It is but repetition to say that a deposit of lithiates in the urine is not due to a morbid condition of the kidneys, but is a sign of functional derangement of the liver, sometimes temporary, sometimes permanent. These lithiates are a product of indigestion. The appearance of lithiates in the urine during the time the liver is engaged in the digestive process, demonstrates the fact that certain peptones instead of being further elaborated in the liver, have been broken up into lithic acid and lithiates. This does not prevent a waste of tissues, but of tissue food as the material which forms this uric acid would under other circumstances have made body tissue. In this same line stands azoturia in which we have an excess of urea. In this we have "excess of urea without diuresis" and excess of urea with diuresis. The first form may be produced by a very slight and almost imperceptible derangement of the assimilative functions, but in the latter, we have the symptoms of a very aggravated form of derangement, accompanied by thirst and morbid craving for food. While this disease is closely allied to diabetes, it is caused by a derangement of the second (not the first) function of the liver. Here we also find "albuminuria," we all know that the presence of albumin in the urine is usually regarded as a certain evidence of disease of the kidneys, we have been taught how to detect it and know that under certain circumstances its presence is ominous of evil, but we know further, that at other times it means nothing. It has been demonstrated that if two or three raw eggs are eaten at once, albumin appears in the urine. Here more albumin has been ingested than can be digested by a healthy liver, so a part simply passes through the liver and is thrown off by the kidneys. Very often the albuminuria is intermittent, albumin being found in the urine passed at night and not in that voided in the morning; in that passed a short time after eating and not in that secreted fasting. We dont pretend to say the liver is at fault in every such case, but it is so frequently, that it is our duty to carefully interrogate it, and we find that many cases of albuminuria (?) are cured when the hepatic disorder has been overcome. We find then that crude albumin may pass unchanged into the general circulation and hence through the kidneys, or the metabolism may take place as an excess of urea, or the albuminoids may be split up into lithic acid, generally combined with ammonia or soda. These conditions may be temporary, the result of acute liver indigestion, or become permanent. In the latter case we will have "renal degeneration as a consequence of the long continued elimination. "Nocturnal asthma" is a result of an excess of nitrogenized waste in the blood. This must not be confounded with the asthma caused by an irritation with swelling of the bronchial mucous membrane. It comes on in sleep, especially after a late heavy meal and is caused by the actual presence in the blood vessels of the lungs of the imperfectly digested food. This is especially the case in persons of a gouty diathesis and an attack is easily excited by particular articles of diet or a spell of indigestion.

Disturbance of the heart' action is very common. There is palpitation, but not that form caused by gas in the stomach or transverse colon. In the latter, the gaseous distention presses the diaphragm up against the heart and mechanically interferes with its action. In the former the palpitation is irregular, accompanied by symptoms of mal-assimilation, waste in the blood, high arterial tension and a badly nourished heart. Sometimes the heart's action is depressed and there may be intermissions with or without fluttering.

Angina pectoris is another common trouble with liver dyspeptics and may prove fatal in advanced life when the heart has become impaired by fatty degeneration. Now, this is not a neuralgia of the heart, but is caused by the spasmodic contractions of the small arteries, excited by the excess of nitrogenized waste in the blood. This causes a high blood pressure in the arteries and may produce either palpitation or angina. This arterial spasm is proven by the hands becoming numb (going to sleep) and the feet cold. Irritable bladder is another consequence. Many cases of so-called inflammation of the neck of the bladder, stricture of the urethra, etc., are the direct result of lithiates in the blood, due to liver indigestion, and can be cured

by restoring the integrity of the liver. Lithic acid irritates the entire urinary tract like fine sand thrown in the eye. Skin affections are common as a result of this blood poisoning.

Upon no tissue does lithic exert a more irritant influence than upon the brain, and, as before mentioned, a temper is developed. Persons naturally mild and even tempered become irritable and peevish when their blood is thus poisoned. Very often there is chronic imsomnia; and after sleep the patient awakes unrefreshed and ready to take offense at nothing. This in brief is a history of the metabolism of albuminoids in the liver, but this condition itself may be a secondary affection produced by derangement of some other organ or function.

Of course, any organic dis-ease of the liver will diminish its digestive and secretive capacity. Disease of the heart, or lungs, by gorging the liver with venous blood may produce this functional disturbance. As has been mentioned the transmutation of the proteids in the liver, assists in the maintenance of animal heat. When the system is in a state of sub-oxidation, the proteids are less able of themselves to generate the heat necessary to complete their nutrition, and instead of tissue food we have lithiates, etc. When the oxygenating process is going on normally in the lungs, this extra supply of heat can be obtained; but when the lungs are diseased the supply of oxygen in the system is diminished, and demands of the liver cannot be complied with, and the second function not being properly performed, we have only impoverished, poisoned blood to nourish and build up an enfeebled body. Suppression of the catamenia and different forms of uterine disease also disturb the workings of the liver. Some of these cases are typical. Dull headache, furred tongue, capricious appetite, constipated bowels, irritable bladders and every symptom of malnutrition. Worry, prolonged mental exercise, or anxiety, not only interfere with the proper secretion of bile, but derange the process of blood-making and oxygenation and induce lithiasis. We are all familiar with these results in the cases of clergymen, students, accountants, etc., who labor with their brains and lead sedentary lives. Before touching upon treatment let me give in a few words the essence of this paper. When food rich in albuminoids is taken in excess of the needs of the system, the excess is split in the liver and it is the disturbance of this function which causes the production of lithic acid and lithiates. Instead of urea we find the liver producing the feebly oxidized and almost insoluble uric acid. A pernicious habit is thus formed which tends to perpetuate itself. The treatment, and this I can only outline briefly must include not only the immediate trouble, but the possible consequenees.

It is not well to resort to mercury as a cholagogue too frequently, as the liver once accustomed to it will not respond to milder stimulants; again, when the kidneys are much impaired the system becomes very intolerant of mercury, and it must be exhibited with great caution. When to give and when to withhold mercury in cases of albuminuria and lithiasis is a question which will frequently puzzle the best physician. In addition to the medicinal treatment is the dietary, and upon it we must lay the greatest stress if we wish to prevent chronic liver indigestion. After what has been said, however, it will not be necessary to go much into detail, if we keep constantly in mind, that alike in biliousness and liver indigestion it is the albuminoids and not the *hydro carbons* which are the *casus belli*. Fruits of all kinds both fresh and cooked are good, provided the stomach which must be consulted first, will tolerate them, and they may be eaten with milk or sugar. The salts in fruit are not in large quantities, but that they are operative, is demonstrative in their anti-scorbutic effects. All vegetables, well cooked, except peas and beans, as these contain a large proportion of casein which is albuminoid. Fish is permissible when plainly cooked and served. Oysters in every style except fried. Fowls may be eaten in fair quantities, but we must not forget that they are rich in albuminoids, especially the dark meat. Pork is simply poison, and veal should be eschewed. Beef is good, but mutton is best. Bread is best eaten cold, but there is no necessity for greater detail. As to drinks, will simply say, that alcohol in any shape is, to put it as mildly as possible, very undesirable, it is a powerful hepatic stimulant, and may be permitted under certain circumstances, but in very limited quantities and well diluted. The habitual use, with

seeming impunity of the so-called table wines simply shows how long suffering and forbearing our livers can be, but the day of reckoning will surely come. In conclusion, allow me to call attention to the great mistake we make in the management of these cases. We too frequently mistake the consequence for the cause and direct all our treatment to the symptoms, losing sight of the fact that our great blood-making-machine is skipping cogs; and when a proper diagnosis is made, we do not prosecute our treatment for a sufficient length of time. A few doses or days of treatment give relief, and we then leave the liver debilitated both by the attack and medication to fight its own battles unaided. In all chronic cases the patients should be kept under medicinal treatment for several months and under dietetic for a year or two. Let me illustrate clinically. In 1871 I was sent home from New York to die; my case could not be diagnosed at first, although I know now I had all the symptoms of liver indigestion in its worst form. The attack culminated in an abscess of the liver, which, adhesion having taken place, discharged into the duodenum. It took about twelve months to make the organic repairs, and ten years to overcome the functional disturbance. During the first two years I took medicine regularly three times a day and don't believe I missed half a dozen doses in that time. For ten years I kept up my diuretic treatment, with medicinal aid at irregular intervals. Had I stopped treatment sooner, I would not be, as I now am, perfectly healthy, with the digestion of an ostrich. Then:

Would'st thou live long and well,
Escape the pangs and pains of hell,
And live a life of joy and ease,
'Bove Galen's diet or Hippocrates'?
Avoid excess of food and drink,
On the welfare of thy body, think;
Guard well that organ—the life giver,
For he lives not well nor long, who *knows* he has a liver.

FUCH'S COLLYRIUM FOR CHRONIC CONJUNCTIVITIS.

℞

Ammonii chloride	0.1	gramme.
Zinci sulphatis	0.25	"
Aquæ destillatæ	40.0	"
M. et add—		
Camphoræ	0.08	"
Dissolved in—		
Spiritus vini diluentis	4.0	"
Croci	0.02	"

Digest for twenty-four hours, stirring frequently. Filter.
Sig.—Eye drops, to be used pure or diluted with equal parts of water.

PRINCIPAL RETURNED WITH INTEREST.

P. J. FARNSWORTH, M. D.
CLINTON, IOWA.

Somewhere about the 25th of July ult. a mother held in her hands a five dollar gold piece. She showed it to the little boy of two years and two months who took it quickly and put it in his mouth gave a little gulp and it disappeared.

They consulted the physician at once, who told them not to be apprehensive and repeated the old joke, "If the coin is good it will pass."

They looked for it for two months and then concluded that it was lost. The child's health was good. The mother remembered that he complained of choking occasionally. After breakfast, of bread and milk, October 22d instant, the child gave a little hack or cough and then threw up the five dollars and nothing else.

It had remained in the stomach without inconvenience for three months. There is no doubt of the genuiness of the coin, but instead of "passing" it was "returned."

PERNICIOUS VOMITING OF PREGNANCY.*

By J. G. CECIL, M. D.,
LOUISVILLE, KY.

I have a case to report which is one of considerable interest to me, inasmuch as three or four years ago I read a paper before the Medico-Chirurgical Society of this city, on the subject of pernicious vomiting of pregnancy. At that time I had never seen a fatal case, but since then a fatal case has been reported to that society by Dr. C. Skinner, and I now have one to report myself. The case was one of a young woman perhaps thirty-five years of age, the mother of three children, and in rather delicate health, who became pregnant and almost from the day of her conception, at least as far as she was able to reckon, she commenced to vomit, in spite of any remedy,

*Read before Clinical Society of Louisville, Oct. 4, 1892.

in spite of everything; she went on to her death from the pernicious vomiting of pregnancy—death by starvation. She vomited about eight weeks; I presume from the size of the fœtus pregnancy was not over two and one-half months advanced. I remember at the time I read the paper before the Medico-Chirurgical Society, the position was taken by several of the prominent members of that Society, that inasmuch as these cases were very rare, and, particularly, as they, in their experience, had never met with such a case, under no circumstances (as I remember the trend of their remarks,) would they advocate relief by miscarriage. At that time I tried to defend the position that miscarriage was justifiable, and took the ground that we ought not to go to that extreme, or allow the patient to go to the extreme of the low typhoid condition which precedes death, but after everything else had failed, to induce miscarriage as a last resort, in order to save life. In the case under question, which, by the way, was under the care of another physician, I only having seen the patient on two occasions, once about two weeks before her death, and again the day before death—at the time of my first visit (two weeks prior to her death), her condition was not so serious in my estimation, or in the estimation of my consultant, as to justify miscarriage at that time; in fact, it was not yet ascertained absolutely that she was pregnant. I do not think anyone is able to say positively that a woman is pregnant at two or two and one-half months, but all the evidence pointed to that conclusion. I found that she had a retroverted womb and suspected that she was pregnant, but was not certain. I turned her in the genu-pectoral position and replaced the retroverted womb, endeavoring to hold it in position with a cotton tampon. I advised the doctor to continue this treatment, I was satisfied that the retroversion was the occasion of the persistent vomiting, as is often the case, and in the event that he could not succeed in maintaining the womb in position, then to dilate the cervix with the finger as far as the internal os, but not through it. When I saw the case the second time, the doctor in charge reported that he had not been able to hold the womb in proper position, and had resorted to dilatation of the cervix as far as the internal os, but with no apparent benefit. I then advised immediate miscarriage, which we produced by dilating the canal and internal os, inserting a catheter; the woman, however, was so far advanced toward death, so weak, that miscarriage was not complete at the time of her death; that is, so weak that the uterine muscular fibres were so thoroughly exhausted that the fœtus was never expelled fully during life. I may add that she had had evidences of miscarriage, these evidences having existed all along and we were hoping all the time this would occur spontaneously. The day she died the doctor made an examination and found the fœtus partly expelled from the womb; she sank rapidly and certainly died from this pernicious vomiting, and I want to put this case on record as such. The urine was examined and no evidences of special trouble found. She had a low grade of fever, which during the last week of her life was similar to the last week of typhoid fever. The first time I saw the patient her temperature ranged from 101° to 102°F.

This patient never retained anything taken as food except the white of an egg. She was fed per rectum as long as she could retain anything. The injection soon produced rectal irritation, and could no longer be used. The accomplished obstetrician, DuBois, divides this subject into three stages, very similar to the typhoid condition, and I thoroughly agree with him. He says it is not right nor fair to the patient to wait until the last stage to perform a miscarriage, because, at that time, the patient is so thoroughly exhausted that the shock of miscarriage carries her off. The time he advocates or indicates as proper to induce miscarriage, is during the second stage; that is, when the woman has a decided fever and is unable to retain any nourishment, when every other possible means, therapeutical or local, dilatation of the cervix and everything else has failed. I perfectly agree in this, and believe if miscarriage is brought on at this stage, the chances of recovery are greater than if it is delayed until the last stage, when all the powers are waning.

The attending physician dilated the internal os upon my advice; that is, I believed in going step by step. We frequently have heard of cases, no doubt all of you have, where ulceration of the cervix

associated with persistent vomiting, has been cured by the single application of nitrate of silver solution, where relief has followed the single introduction of the finger into the internal os. I think many of these cases have been benefitted by gradual dilatation of the cervix, that is, step by step, the finger eventually getting to the internal os, as we did in the case under question, at the last moment. My advice to the attending physician was that as long as she was having evidences of a miscarriage, that is, having pains, which seemed to indicate that she might have a miscarriage, possibly any dilatation would excite it, and the least we did the much better her chances would be. I believe that the internal os can be dilated with much advantage in these cases, but I believe also that the risk of miscarriage would be much greater. With the finger you can dilate the os to that extent and probably not bring on a miscarriage, though if the tendency was very strong, I am inclined to think miscarriage would be induced.

COCAINE POISONING.

By J. B. MATTISON, M. D.,
MED. DIRECTOR, BROOKLYN HOME FOR HABITUES.

In November, 1886, at a meeting of the Neurological Society, Dr. Wm. A. Hammond, speaking of cocaine, said, "He did not believe any dose that could be taken was dangerous." This statement—mistaken, misleading and dangerous—was promptly challenged by the writer; and, in two papers—"Cocaine Dosage and Cocaine Addiction," London *Lancet*, May 23, 1887; and "Cocaine Toxæmia," *La Tribune Medicale*, Paris, Jan., 1 1888—seven deaths and 119 less lethal cases from this drug were cited; a record that impelled the *British Medical Journal* to editorially assert "if it were needful to produce more proof of the unsoundness of Dr. Hammond's statement, Dr. Mattison has effectually done this."

In a third paper—"Cocaine Poisoning," Medical and Surgical Reporter, Oct. 24, 1891, covering the record to March, 1891—six more fatal cases and over eighty less toxic were noted, making in all thirteen deaths and nearly two hundred other cases.

In a fourth paper—soon to appear—we shall note those reported from March, 1891, to September, 1892, and among them the one here detailed, for which I am indebted to the courtesy of Dr. G. B. Cushing, House Surgeon of Bellevue Hospital, in whose service it lately occurred.

A. B., strong, healthy man, walked into hospital, suffering from retention of urine. Had clap twelve years ago. During last five years, occasional trouble in urinating. On inserting catheter found a stricture four and a half inches from meatus. To prevent pain and spasm, one drachm of a four per cent. cocaine solution was thrown into urethra, held a half minute, and then allowed to escape. Almost at once, patient became very excited, with largely dilated pupils, and in a few seconds went into violent convulsions, so severe that it required the combined strength of doctor and nurse to hold him on the operating table. Nitrite of amyl was promptly used, but there was not the slightest reaction, and in four minutes the man was dead.

The autopsy revealed nothing abnormal except intense congestion of heart, lungs and brain.

This case emphasizes the need of care in all cases of cocaine anæsthesia, and makes pertinent the reiteration of these conclusions:

1. Cocaine may be toxic.
2. This effect is not rare.
3. There is a lethal dose of cocaine.
4. This dose is uncertain.
5. Dangerous or deadly results may follow doses usually deemed safe.
6. Toxic effects may be sequence of doses large or small, in patients young or old, the feeble or the strong.
7. The danger is greatest when given under the skin.
8. Cardiac or renal weakness increases this risk.
9. Purity of drug will not exempt from the result.
10. Caution is needful under all conditions.
11. Réclus' method, Corning's device, or Esmarch's bandage should be used when injecting.
12. Nitrite of amyl, hypodermic morphia, hypodermic atrea, alcohol, ammonia and caffeine should be at command.

Brooklyn Avenue, Brooklyn.

Society Reports.

THE CLINICAL SOCIETY, OF LOUISVILLE.

Stated Meeting, Oct. 4th, 1892.

THE PRESIDENT, Dr. P. Guntermann, in the chair:

CALCAREOUS DEGENERATION OF A FIBROID TUMOR.

DR. W. H. WATHEN: About two or three months ago a patient was referred to me by Dr. J. M. Mathews, who had been under his care for some time with intense trouble referred to the rectum. Upon thorough examination, he reported that he could find no disease whatever in the rectum, and thought there must be something in the pelvic cavity outside of the rectum that would account for this constant trouble. It seems that this woman had been treated for several years by other physicians, before she came under Dr. Mathews' observation. On examination I found in Douglas' sack a movable tumor, very hard and about the size of a hen egg, which I supposed accounted for all her trouble. I diagnosticated fibroid growth, but its origin I could not make out; in fact, the diagnosis was by no means positive, because I do not believe it possible to make an absolutely correct diagnosis in these cases. The woman was operated on about eight weeks ago, and the specimen that I exhibit to you, removed. There was nothing unusually interesting either in the operation or progress of the case. She made, as she ought to have done, an uninterrupted recovery and has none of the symptoms she complained of before the operation. But my special reason for reporting this case is, that while it is not entirely unique, it is an unusual condition, as may be very easily seen upon examination of the specimen. It is a fibroid growth with calcareous degeneration. Its origin, as you will see, is peculiar; it is in the folds of the broad ligament, and has no connection with the ovary, tube or uterus. There are a few cases of this nature recorded, but they are very rare and probably many laparotomists of large experience have never met with such a case. Dr. Dugan assisted in the operation, and Dr. Mathews was present.

DISCUSSION.

DR. J. A. OUCHTERLONY: What Dr. Wathen has said is very interesting, but there is something left out, which I think is essential to our understanding of the case in all its bearings. He mentioned that the woman had been suffering from trouble, and she was relieved, but he failed entirely to state in what the trouble consisted; what were the symptoms which the presence of this tumor had given rise to.

DR. J. M. MATHEWS: This woman was under my observation for about a year. She complained almost entirely of rectal pain, aggravated or increased during defecation. So well marked was this symptom that I suggested putting her under the effect of an anæsthetic and investigate the rectum, which I did. Chloroform was given her, and divulsing the sphincter I searched the rectum but could not find any well defined ulceration, or indeed inflammation; however, the simple divulsion of the sphincter gave her considerable relief for two or three months. She came to my office several times very much improved, but after the lapse of several months she complained of the same distressing symptoms, which she said had become unbearable. I made another careful examination of the rectum with speculum, but finding nothing I referred her to Dr. Wathen, who made an examination and found this tumor which I had been unable to detect; perhaps had not examined her in the manner or by the method employed by him. It was suggested that an operation was advisable, to which she readily consented, because she said the pain had become unbearable. She was promptly relieved by the operation, and I believe the tumor which you see here, was the cause of all this rectal distress.

DR. W. C. DUGAN: I am rather surprised that it was fibroma; I was under the impression that it was a par-ovarian sarcoma. Am very glad for the patient's sake that it was fibroma.

DR. J. A. OUCHTERLONY: The case reminds me of a post-mortem examination I made a good many years ago, in which there was a double tumor of the broad ligament. The tumor on one side was about as large as the head of a child two years old, on the other it was somewhat smaller. They were ovoid in shape, involving the whole broad ligament; neither ovary could

be distinguished, and both tumors were the seat of calcareous degeneration. The nature of the case had not beem determined during life. This is the only case of calcareous degeneration of neoplasms occurring in the broad ligament that I remember ever having seen, and I believe this condition to be very rare.

VAGINAL DOUCHE AFTER VAGINAL HYSTERECTOMY.

Dr. W. H. Wathen:—This is a uterus removed from a woman forty-four of age. The history of the case is about as follows: For a year preceding the time she applied to me, she had been having a discharge from the vagina of, first a muco-sanguineous character, then a mixture of blood and pus, and finally a well defined hæmorrhage, which, she supposed, was a return of the menstrual function. She had some pain and weight in the pelvis. Her husband, a prominent physician, then examined her and detected what he supposed to be an incipient epithelioma. He treated her by local applications and vaginal douches for six months, when he referred her to me. The hæmorrhage had gradually increased and for three months before she consulted me, it had been almost constant. The posterior cervix was involved, and a portion of the anterior cervix and posterior vaginal walls down to nearly the bottom of Douglas' pouch. She was very anxious to have the organ removed, and her husband insisted upon it. About six or seven weeks ago a vaginal hysterectomy was done. I neglected to say that the womb was completely retroverted, lying upon the rectum, but it was not adherent. The only apprehension I had in the removal of the womb was the difficulty in getting far enough back to go behind the malignant growth and not invade the rectum. The womb was removed without any especial trouble and no untoward symptom worth relating developed in the history of the case, until on the morning of the fifteenth day. Her regular nurse had been dispensed with on the fourteenth day; the nurse attending the convalescing patients at the infirmary took charge of the case, and, as is her custom, with a desire to preserve cleanliness, she gave a vaginal douche of about as much or more than a quart of bichloride of mercury solution 1 to 1000 or 1 to 2000. Very little of the water returned, but the nurse continued to inject it all. The woman began to suffer intense pain. The nurse thinking that possibly the solution was too strong, injected some water without any bichloride in it. how much I do not know; she said about a quart, she thought, and very little of that returned. I was telephoned that the woman was suffering intensely and sent my nurse at once who telephoned the condition, and gave the patient a hypodermatic injection of morphine. I saw the patient in an hour and the water was flowing from the vagina, keeping everything wet; about every five or ten minutes she would have quite severe labor-like pains, when the water would gush from the vagina, showing that it had been forced into the peritoneal cavity. She suffered so much that it required one-fourth grain of morphine about every three hours until the next day, when the pains gradually grew less but continued for probably three days before she was entirely relieved. I observed the next morning that she was passing no urine, and upon introducing a catheter into the bladder, only a dram or so came away. The nurse informed me that evidently the character of the water then was practically urine. The catheter was retained and part of the urine escaped through it at first, gradually increasing until at the end of ten days it all passed through the catheter, the wound in the bladder and in the peritoneal cavity having closed. I report this case to emphasize my position expressed three years ago before the meeting of the American Association of Obstetricians and Gynæcologists, that vaginal douches following vaginal hysterectomy are practically of no advantage, and may result in serious injury by forcing the solution, bichloride or what not, and necrosed tissue, into the peritoneal cavity. I was severely taken to task then, others claiming that water injected into the vagina would always run out; but here is a practical demonstration that it went into the peritoneal cavity. I was surprised that the solution of bichloride should have caused so little trouble, because it must have come in contact with a considerable portion of the peritoneum, and organs of the pelvis. I received a letter from her husband about a week ago; he says she is doing well and retains her urine for nine hours.

I would like to call attention to one

other point: About a year and a half ago, I lost a patient from vaginal hysterectomy, caused I am sure by the neglect of a precaution I now take. It was evidently caused by failure to remove by curetting all the infected tissue. Everything used in the operation, and the entire cavity should be thoroughly sterilized; every suspicious particle of tissue carefully scraped away, the cavity thoroughly washed with bichloride solution and tamponed with iodoform gauze. I think that many deaths from vaginal hysterectomy have resulted because of failure to carefully cleanse and scrape away all the infected tissue, thereby admitting the poisonous germs into the the peritoneal cavity.

DISCUSSION.

Dr. W. C. Dugan: Concerning the occurrence of malignant growths, or malignant diseases in young persons, I saw a patient a short time ago, aged twenty-two years, who was suffering with a peculiar ulceration of the cervix; suspecting malignancy, I cut out some tissue and gave it to a microscopist for examination, and he pronounced it unquestionably malignant.

Dr. J. M. Mathews: In regard to the point made by Dr. Dugan, I wish to state that I lost a young lady patient, eighteen years of age, with malignant trouble of the rectum, and a young boy, seventeen years of age, of the same trouble.

Dr. A. M. Vance: I would like to mention a case I saw recently at the Johns-Hopkins Hospital, operated upon by Dr. Kelly by vaginal-hysterectomy. The operation was quite successful, and the woman made a good recovery. At the time I saw the patient he was very much surprised to discover in the vault of the vagina a mass of protruding tissue. Upon investigation he became convinced that it was omental hernia, which was easily removed by galvanic-cautery, only a very small pedicle being present. The tumor protruding was about the size of an English walnut. This shows that the opening remained some little time after vaginal-hysterectomy.

Dr. J. G. Cecil: In this connection, I want to report a case that I saw once which was operated on by Marcy, and in which there was complete closure of the opening, and the trouble had recurred in the cicatrix. Another case I remember was operated on by Price, in which there never was a closure of the opening through the vault, but in the last case there was a recurrence of the trouble probably within six weeks or two months. The opening never did close yet there was no trouble resulting from the vaginal-douches, that is, no such trouble as Dr. Wathen experienced in his case.

Dr. W. C. Dugan: Did you not attribute the trouble of non-union to malignant growth which was not wholly removed?

Dr. J. G. Cecil: We thought failure of the opening to close was due to early recurrence of the malignant trouble.

Dr. A. M. Vance: In the case referred to by me, operated upon by Dr. Kelly, the mucous-membrane coming up to this little mass, was perfectly soft and gave no evidence of infiltration, nor was there any in the mass after removal. The pedicle was about one-quarter of an inch in diameter.

Dr. W. H. Wathen: The trouble in this case was evidently due to the fact that in operating, the vaginal-vault was left open, and the omentum immediately slipped in, blocking and preventing its closure. I would like to ask if ligatures were used in the operation.

Dr. A. M. Vance: The operation was done with ligatures, some of which were still on.

UREMIA CAUSED BY MALIGNANT TUMOR.

Dr. J. A. Ouchterlony: I will mention a somewhat unusual case that came under my observation. A lady past middle age, who had several years ago ceased menstruating, noticed the latter part of last year a sanguineous discharge per vaginam, which disturbed her considerably. At first she thought it was a return of menstruation, but it occurred at irregular intervals and she suffered some discomfort in the lower part of the abdomen, not very definitely located. At last she consulted me; I examined her and found an epithelioma of the cervix and upper part of the vagina, so extensive in its implication of the surrounding tissues, that I did not think an operation was at all likely to prove servicable. I treated her with astringent washes, etc.; in the course of

time she began to suffer more pain, which became so intense that I put her on small doses of codeia, repeated several times during the twenty-four hours. This kept her comfortable, and the washes did away with the unpleasant discharge and she got along very nicely. I told the family the nature of her trouble, and this summer the question was agitated by some of her relatives whether something could not be done. A friend of mine saw her with me, and agreed that it was not a case for operation. I went away on my vacation and in the meantime she had to increase the dose of codeia so that she took about one and one-half grains three or four times a day. When I returned early in September, I found her at home after a sojourn in the west, looking better and having become stronger. After I had been at home a week or so, I was sent for one day, and she informed me that she was unable to pass water. I gave her a diuretic, which produced no impression at all; then I introduced a catheter and got nothing but some sanguineous, milky fluid. I employed a silver catheter which could be moved around, using as a probe, and found that the posterior walls of the bladder had become involved in the malignant processes, and was almost completely filled with this epithelial mass. She was suffering from nausea, and could retain nothing; I gave her some wine of cocaine which seemed to relieve the nausea, and she took a little nourishment, but the urinary function was never re-established, and she died after two weeks, in which time she had never passed any water at all; some fluid perhaps amounting to a tablespoonful escaped per urethra in the course of each twenty-four hours. While this was going on there was a soft fluctuating tumor developing in the right flank. My diagnosis of the case was as follows: "Malignant processes involving the orifice of the ureters, preventing the entrance of the urine into the bladder," and for that reason she was enabled to live so long without passing any water. She had a few convulsions, and all of a sudden one evening she had a severe convulsion and was gone.

I do not remember every having seen exactly the counterpart of this case; it interested me a great deal. It is an unusual way for malignant disease of the uterus to terminate.

DISCUSSION.

Dr. T. P. Satterwhite: I believe it is common for malignant troubles to cause uremic poisoning.

Dr. J. A. Ouchterlony: Why should there be uremia in malignant disease of the uterus, unless the disease involves the kidneys?

Dr. T. P. Satterwhite: I have seen two cases of malignant trouble of the mammary glands, both patients dying of uremic poisoning.

CANCER AND LIFE INSURANCE.

Dr. J. G. Cecil: The case reported by Dr. Ouchterlony is certainly a very rare one as far as my observation goes, in the manner of its termination. I have often wondered why it was we see extensive disease involving the anterior vaginal walls, and that the ureters so frequently and so generally escape. This case of cancer recalls to my mind one of some importance from an insurance standpoint, which came into my knowledge recently. A woman down town was examined by two gentlemen for life insurance, and she gave as far as the reports went, a clear history with the exception that she did not give any history of malignant growth; but it was afterwards learned that she had had a small growth taken from the alæ of the nose, which had been diagnosticated by an irregular as cancer, some two or three years previous. She passed the examination into a company which is reasonably rigid, I think, for three thousand dollars, and a short time afterward, within a week or two at least, she had a hæmorrhage, and sent for Dr. Turner Anderson, who went to the house and found the woman out in the garden working about the flowers or vegetables. The doctor asked her if anyone was sick, and she said no, and he told her he had been summoned to that house; she replied that perhaps it was herself, as she had had some little hæmorrhage and wanted to know about that. He made an examination and detected very easily an extensive carcinoma of the cervix. She was past the menopause, probably fifty-five years of age. The next day after the examination, I believe, a friend of hers, relative, perhaps, came to Dr. Anderson and asked him what he had learned by his investigation. Dr. Anderson told the party he had learned that the woman had

a cancer. This lady was informed of the fact that she had a cancer, whereupon she laid down and died. She died within a week or ten days from the date of Dr. Anderson's examination. The question that is agitating the insurance company is whether they will have to pay the policy or not. I do not know exactly how she died, but the method of her death as related by the physician in attendance would seem to indicate acute peritonitis.

DISCUSSION.

Dr. A. M. Vance: I remember the case of a young medical student, where a tuberculosis process closed the ureters, and the patient died in a short time with convulsions. No hydro-nephrosis developed, and he died in three days after suppression had commenced. The process commenced in the testicles and went from that to prostate, thence to the bladder walls, shutting off the ureters.

Dr. J. M. Mathews: The point made by Dr. Cecil is an important one in relation to life insurance. Five years ago I read a paper before the State Medical Society, of Kentucky, on the subject of the importance of rectal examinations by life insurance examiners. In that paper I cited five cases, one of which I wish to mention briefly: A gentleman was referred to me by Dr. Leachman, for some inflammation of the rectum, supposed to be piles, I made an examination with my finger and detected quite a large nodule. I asked the gentleman to bring Dr. Leachman with him to my office; after a delay of about a week the Doctor came with him. I had the Doctor touch this nodule, which was about three to three and one-half inches up the rectum, saying that I thought it was malignant. At that time the Doctor hardly thought so, as the man appeared to be in excellent health. The man was given comparatively little treatment; I gave him an injection, and he said he felt improved. He then left for a long trip west and was absent several months. On his return he came to my office, stating that he was positively relieved had no trouble at all. I examined the rectum and found ulceration considerably increased. He then left my office and made application to one of the life insurance companies for a ten thousand dollar policy, and was accepted. The growth rapidly extended and in less than six months from that time the man was dead, evidently from perforation caused by cancerous growth. This growth could be detected by simply passing the finger in the rectum, and if the examiner for life insurance had done this, it would have saved the company ten thousand dollars. It is my experience that these growths occur in the rectum often without any pain at all; that the rectum may be almost closed by the growth without causing pain; and, that they can be easily detected simply by an examination with the finger, without the aid of a speculum.

Dr. W. H. Wathen: The case referred to by Dr. Ouchterlony is unusually interesting, and, as far as my experience goes, entirely unique. I think I have seen relatively more cases of cancer of the womb than of any other disease, and have never known a case resulting as he has described. You seldom find the ureters obstructed; the flow of urine constantly coming away, the pressure from behind forcing it through, prevents the passage becoming obstructed; but in this instance doubtless something encouraged the rapid growth of the cancer, which obstructed nearly the entire flow. From the explanation given by Dr. Ouchterlony I feel sure the uremia was due to the obstructed ureters. I have never observed any relation between cancer and kidney complication, and do not see why there should be any, unless the kidneys or the ureters are involved in the cancerous growth.

Concerning Dr. Cecil's inquiry as to the part cancerous disease of the uterus assumes toward life insurance, I think this is quite an important matter, but one however, that will probably never be fully and practically appreciated, for the reason, that women generally will not complain to insurance examiners of any symptom that would indicate a disease of this nature. It has probably been the experience of all of us in the treatment of cancer of the womb, that patients do not apply for examination until the disease has progressed beyond operative means. I think nine-tenths of the patients, if not nineteen-twentieths, that have consulted me, have gone so far that an operation could not be performed. Many of these I have examined when they had complained but little, and had not suspected malignant disease.

Dr. W. C. Dugan: I remember a few

years ago hearing Thomas make the statement that the return of menstrual flow after the menopause usually meant malignancy, and in such cases the patients should be subjected to careful examination at once. This clinical fact, I am convinced, is not generally appreciated.

Dr. J. A. Ouchterlony: I have read of a number of cases where there was a return of the flow, which continued with perfect regularity for a considerable length of times in which there was no malignancy.

Of course such cases are rare, but they do sometimes occur.

Dr. T. P. Satterwhite: I wish to state in connection with Dr. Mathews' remarks, not long ago I was called to see a lady about seventy years of age, the very picture of health. She said she had some little trouble with constipation, for which I prescribed saline waters. She sent for me again in two or three weeks; I examined her rectum and found it was nearly closed; as well as I could judge from my index finger, I do not think the opening through the stricture was larger than one-quarter of an inch, and she was as healthy and robust a looking woman as I ever saw.

PERNICIOUS VOMITING OF PREGNANCY.

Dr. J. G. Cecil: (See page 726)

DISCUSSION.

Dr. W. H. Wathen: I am opposed to the induction of miscarriage in cases of this character, but I feel that we may be justified in resorting to means that may bring on miscarriage, not for the purpose of bringing it on but for the relief of the nausea. I should not hesitate where I had a patient that had resisted all other means, whether she might be threatened with miscarriage or not, to gradually and carefully with my finger, dilate the entire canal to a limited degree. Sometimes the dilatation in a case of threatened miscarriage might have a soothing effect by relieving the irritation within the cervical canal. There are some instances where dilatation has resulted very rapidly in miscarriage; in others where it does not result in it at all. I have seen the neck dilated to the extent of a half dollar in a woman pregnant fourt and one-half months, and the sound in roduced several times between the membranes and the walls, not bringing on a symptom of miscarriage. The physician who did this contended that the pregnancy was extra-uterine, because he had introduced the sound without producing miscarriage. I introduced my finger and found the head of the child easily within the membranes. She went on to full term.

I have found a number of cases where a properly adjusted pessary has been the means of preventing miscarriage in retroverted wombs.

GONORRHEA.

Dr. John A. Wyeth, in a clinical lecture at the New York Polyclinic, said: My idea about gonorrhea is that we should treat it just as we do an acute abscess: that is, by drainage, with just as much asepsis as possible. Let the urethra hang downward, with a bag of some sort loosely attached to it to catch the discharge. Do not have it tightly bandaged or plugged up with cotton. In a specific urethritis, where the inflammation has extended into the deeper layers of the epithelium, the various bichloride and zinc injections are not likely to do much good. In an ordinary non-specific urethritis, however, where the inflammation is superficial, you can inject with good results. There are certain remedies which will increase the amount of urine and render it aseptic, so that you can use the bladder as an irrigator in gonorrheal inflammation. Among these remedies is boracic acid, or better still, the oil of gaultheria. This drug will absolutely sterilize the urine. You can give five or six drops every three or four hours. During the later stages of inflammation, mild solutions of the sub-acetate of lead can be used, which will help keep the urethra clean. A syringe with a short nozzle should be employed so as to only just enter the meatus. The injection should be of moderate size, so as not to over-distend the urethra. During the acute stages I instruct my patient to take a warm sitzbath night and morning. When the acute stage has subsided the administration of some of the so-called blennorrhetics will be found beneficial.

I have found the capsules containing Santal-midy, a preparation made from sandal-wood, a very good thing. I consider these superior to the old-time cubeb preparations, which are liable to disturb digestion.—*Indiana Med. Journal.*

Bacteriological Notes.*

A Method for Obtaining pure Cultures of Tubercle Bacilli from Sputum:—Dr. E. Pastor (*Centralblatt f. Bakteriologie u. Parasitenkunde*, xi, 1892 p. 233) has announced a method for obtaining pure cultures of tubercle bacillus from the sputum. He selects sputum which contains a very large number of bacilli and comparatively few other bacteria. The patient is then made to wash out his mouth repeatedly with sterilized water after which he expectorates in a sterile dish. This sputum is emulsified by shaking it up with sterile water and any coarse particles filtered off with fine gauze. A few drops of the filtrate are added to tubes of liquid gelatine (10 per cent.), thoroughly mixed with it after which it is poured out on plates. These are properly covered and left at the temperature of the room. In the course of a few days the other bacteria, present in the filtrate, develop colonies. By means of a hand lens areas can be found on the plate which are free from colonies. These are removed by means of sterile instruments and tubes of inclined blood serum inoculated with them. These are kept at the body temperature in an incubator. The author always obtained as many as one, (frequently more) cultures of the tubercle bacillus out of a series of ten inoculations. Many of the tubes became contaminated owing to the non-development of certain bacteria at the ordinary temperature. Better results were obtained from the fluid in the cavities of phthisical lungs which as would be expected contain more tubercle bacilli and less impurites than the sputum.

Appearance and Spread of Microorganisms in the Alimentary Canal of Animals:—Popoff (*Wratsch, 1891, No. 39.*) examined bacteriologically the meconium of calves and the contents of the intestinal canal of newly born cats and dogs. In the latter case some of the animals had been suckled, others had not. The conclusion reached was that the meconium contains under physiological conditions neither ærobic or anærobic bacteria but it afforded a good medium for the development of bacteria that might be introduced. The time of the appearance and spread of the bacteria depends entirely on the milk. The only way by which bacteria can enter the intestinal canal is by the mouth. Bacteria can be demonstrated in the meconium twenty-four hours after birth.

Brienstock maintained that bacteria would not be found in the meconial feces of children fed only on milk. Echerich however discovered bacteria in the rectal contents in from four to eighteen hours after birth. In the light of their former experiments the results of Popoff are of considerable importance.

A Pus-Producing Bacillus Obtained from Earth.—Dr. Bolton (*The American Journal of the Medical Sciences, ciii, 1892, p. 673*) described a bacillus which he isolated from earth by inoculating rats. The bacillus resembled morphologically the bacillus of diphtheria. Many of them are bent and narrower throughout the middle than at the extremities. It does not take the Gram stain. It develops most vigorously in a slightly acid medium. In rats, gray mice, rabbits and usually in white mice a subcutaneous inoculation with a small quantity of a pure culture produced an abscess confined strictly to the seat of inoculation. The injection of .5 cc of liquid cultures in the veins of rabbits produced in some cases multiple abscesses, especially in the joints and kidneys. Subcutaneous inoculations produced in one case abscesses of the joints in a white mouse. The abscesses developed very rapidly after the inoculation, but suppuration ceased as soon as they were opened. The animals appeared to suffer no other inconvenience. The bacteria were found aggregated in small and larger irregular clumps in the pus many of them lying in the pus-corpuscles. Metastatic abscesses were formed only when the bacteria were injected into the circulation otherwise the abscess remained strictly confined to the seat of inoculation in rabbits, white rats and gray mice.

In the same article the author gives an interesting account of the cultivation of tetanus bacilli. He obtained pure cultures of these bacteria from different specimens of soil and also from a case of human tetanus by the use of Kitasato's method.

Abstracts.

ACTUAL, NOT TEXT-BOOK, EXPERIENCE WITH CASES OF ECTOPIC GESTATION.*

By DR. JAMES F. W. ROSS,
TORONTO.

After showing the want of reliability of text-book lore, since they for the most lack that knowledge gained by actual experience and hence are given to lead the student astray, the author credits the pioneer work of Lawson Tait coupled with his teachings, to have been the means of saving several hundreds of lives. Ross confines himself entirely within the realm of his own personal experience and sets forth many instructive facts, well to be borne in mind by the general practitioner so the patient in question may receive prompt surgical assistance.

History.—(*a*) *Sterility*: "Which becomes the cause of fertilization of the ovum and its non-removal from the tube," he explains by the fact that "many of these patients contract gonorrhœa soon after marriage, but to a minor degree; the ciliated epithelium is shed, and the tube is functionally imperfect." (*b*) *Supposed miscarriage*: Experience shows that uterine bleeding may occur when a pus-tube or ovarian cyst is present, can only be relied on if the decidua is found. (*c*) *Pain*: Of great importance. The woman has been practically a well woman until it set in, no evidence or history of recent gonorrhœa, no miscarriage, no intermittent attacks of inflammation, but while progressing well, though barren, she suddenly, in the midst of health becomes an ill woman. Ectopic gestation is the only disease that will produce this condition.

Digital examination may be puzzling in that the condition feels neither like a pus tube or cystic ovary, too soft for a fibroid with a pedicle, too hard and too movable for a hydrosalpinx, that takes some eccentric position between uterus and bladder, and simulates that disease of the ancients, "pelvic cellulitis." A guess of ectopic gestation will probably be correct.

Rupture of an ectopic gestation may or may not give rise to symptoms; a woman may be going round with blood in her abdomen without showing any definite signs of its presence; and yet *peritonitis* may supervene at any moment. This is shown by an elevation of temperature and pulse, and calls for immediate surgical interference, otherwise the patient's life will be sacrificed. Hematocele is nearly always connected with ruptured tubal pregnancy, to substantiate this the author showed a specimen of an enormous suppurating hematocele, the fetal sac was almost overlooked, lying as it did, high up among the intestines. The author reported seven cases with six recoveries, results which amply justify his conclusions. "In all cases of obscure miscarriage with a doubt as to the previous abortion, with a mass in the pelvis and unaccountable pains, a consultation should be called before the patient lapses into a critical condition. An operation should then be performed, partly exploratory and wholly curative."

*Read before the Medical Society of the County of Erie, Buffalo, June 14, 1892.

THE TREATMENT OF OBSTINATE HICCOUGH.

It is doubtless perfectly true that the treatment of hiccough has not received much notice at the hands of the writers of text-books in this country. But the reason of this probably is that the symptom seldom attains to any serious proportions in this part of the world, so as to call for relief by the medical man in attendance. When, however, hiccough acquires an obstinate persistency, for the relief of which therapeutic aid is urgently needed, difficulties may be met with. A case in point is recorded in an Indian contemporary, where a retired officer aged 76, who had been suffering from acute congestion of the liver became affected with obstinate hiccough, which set in as a most alarming and distressing symptom. Everything was tried in the way of drug treatment which could be suggested, but without avail. One day, however, some beef tea was taken, which incidentally caused the patient to vomit. For a time, in consequence of this, the hiccough was relieved; whereupon the practitioner determined to try an injection of apomorphine, and the result was that vomiting was produced, and the hiccough ceased permanently. Altogether the symptoms persisted incessantly for seventy-two hours, and caused much distress to the patient. Physostigma has been recommended as useful in these cases.—*Med. Press.*

THE RELATION OF THE SO-CALLED MINOR GYNÆCOLOGICAL OPERATIONS TO INTRA-PELVIC INFLAMMATION.

L. S. McMURTRY, M. D.,
LOUISVILLE, KY.

The author calls attention to the advance of civilization, the departure from simple habits of agricultural life, the accumulating influx of European pauper population and an increase of vice, as augmenting the prevalence of specific inflammatory disease of the pelvic organs. The ready infection of the intra-peritoneal structures during an unprotected labor or puerperium, as a conspicuous cause of intra-pelvic inflammatory disease.

Under the head of *pernicious effects of unnecessary examinations*, he states that not every woman with pain in back and head at menstrual period should be regarded as a subject of uterine or ovarian disease, salines, hot sitz baths and rest generally giving relief. Opium is decidedly contraindicated and dangerous. The author recognizes mechanical dysmenorrhœa either from cervical stenosis or imperforate hymen, but claims their proportion to be limited, and when local examination becomes necessary in the unmarried, she should be anæsthetized. The sound he denounces as a bearer of infection, and a means by which the uterine walls have been punctured, hence dangerous and useless.

Under the *use of caustics and chemical solutions*, the doctor speaks truly and feelingly: "I could recite here case after case from my own practice, showing beyond question that mild forms of pelvic inflammation have been converted into serious and acute grades by this treatment, and that disease of the tubes and ovaries dated its activity from the time such treatment was instituted." He therefore endorses Emmet's teachings on the evils of intra-uterine medication.

Dilatation of the cervix uteri resorted to by some for sterility, dysmemorrhœa, on the assumed diagnosis of stenosis of the cervical canal. 1. Sponge or tupelo tents, often within twenty-four hours give rise to elevation of pulse and temperature and the patient has an attack of pelvic peritonitis and its sequelæ of chronic inflamed appendages. 2. Graduated hard rubber dilators, produce a traumatism which may extend itself readily through communicating channels to the peritoneum. 3. Steel dilators most often used, have been erroneously credited with curing menstrual disorders and nervous disturbances associated therewith; and have no place in nervous dysmenorrhœa,—the author recognizes the necessity for dilatation of the cervical canal, by a gentle hand under asepsis as a preparatory step in the removal of pathological growths from the uterine cavity, but feels the indiscriminate and persistent use of dilatation is a common and prolific cause of disease of the uterine appendages.

Indiscriminate Trachelorrhaphy. The operation, one of the most appropriate and efficient in deeply torn ulcerating cervices, has been widely abused in having been performed for every variety of pelvic disease and almost every form of nervous disorder. It has unfortunately been also done in cases of unrecognized intra-pelvic inflammations or the lack of proper precautions and aseptic methods have given rise to more serious conditions than the operation was undertaken for.

The routine use of the curette. Its usefulness in the removal of fungous growths from the endometrium, or removing all kinds of detritus from the interior of the uterus, has long been recognized. Its use in simple endometritis (a rare disease) is questionable, results often showing an aggravation of intra-pelvic disease.

In conclusion the author presents the following summary: 1st. Etiology of intra-pelvic inflammation (salpingitis, ovaritis, and peritonitis) may be therefore: (1) puerperal; (2) specific (3) post-operative (traumatic).

2. Unnecessary and uncleanly examinations, with introduction of the sound, may cause by traumatism and infection, pelvic inflammation.

3d. Forcible dilatation, with steel instruments, sponge tents and other instruments, may beget intrapelvic inflammatory disease. This operation has a very narrow sphere of utility, and is usually performed upon erroneous pathological data.

4th. Operations on the cervix with associated disease of the appendages is dan-

*Read before the Med. Soc. of the County of Erie, June 14, 1892.

gerous. The treatment of lacerations by caustics and astringents is never satisfactory and always dangerous. Trachelorraphy is an operation of high utility, but requires discrimination in application and skill in execution in order to obtain good results. It is often the initial step in tubo-ovarian disease of severe type.

5th. Curettement, while of unquestioned value in removing neoplasms and detritus from the endometrium, is abused as a method of treating inflammatory conditions of the pelvic organs. The curette is an instrument capable of causing extensive lesions, that may light up an inflammation extending to the appendages and peritoneum, or aggravate a pre-existing inflammation therein.

THE NATURAL HISTORY OF PELVIC INFLAMMATIONS.

By JOSEPH PRICE, M. D.,
PHILADELPHIA.

The author begins with the pregnant remark that all affections should be studied from the clinical and symptomatic standpoint, this should be reinforced or corrected by such pathological data presentingthemselves along the line of investigation.

The various forms of pelvic disease studied from this standpoint have enabled the author to assert definitely that in his experience he has never met with a broad ligament abscess; in the most purulent inflammation discoverable in the broad ligament, in tubal and ovarian disease, he has always found the ligament intact. It might be often folded on itself, glued together, and apparently fused with the abscess cavity, but careful dissection would free it, and the ligament, except for inflammatory cloudiness due to adhesions, was in no way attacked by the pus deposit; he states further that "this is the invariable rule when removal is made *in toto*. This is why almost without exception all these pelvic tumors are removable. The broad ligament is the swing upon which is held the inflammatory neoplasm, and when intestinal and omental adhesions are loosed, the whole deposit may be lifted out and removed."

The conclusions drawn from the above facts, are, that almost without exception the *sources of inflammation come from the outside.* Its natural passage is through the uterus, along the tubes where it is likely to stop since the fimbriated end is prone to glue up, but this often happens only after the ovary has been infected thus giving rise to the ovarian abscess and its possible subsequent complications. The causes for pelvic inflammation may be natural or artifical—referring to the latter he states: "*I am sure that many women are treated into pelvic disease,*" and cautions about the use of the improper use of the vaginal douche, viz; during the menstrual period, or used at any time with great force, the danger being the occurrence of possible traumatic inflammation; the use of the sound and intra-uterine application, etc., are mentioned as other causes.

Under the head of natural causes, are gonorrhœa, badly-handled labors and abortions, and the accidents to menstruation, those belonging to this latter class could be avoided, if proper instruction regarding necessary care during menstruation, attention to proper hygiene and the ruder forms of exercise and the fatigue of the ball-room.

The exact history of previous pregnancies, abortions and labors, their management, excessive douching at the puerperal period with excessively strong irritating solutions, the use of instruments at labor, the after-history in reference to discharges, retained placenta and long-continued bleeding are all competent to produce trouble along the channels already designated; he further states that, "the diagnosis, apart from history, must rest upon digital examination. The presence of lateral masses in the pelvis, our old cellulitic deposit, must give us our point of inquiry. First the uterus should be differentiated, after which, taking this as the objective point, all other relations are to be decided,—the ovarian abscess and its subsequent complications."

Among the causes of pelvic inflammations he enumerated: The presence of a well-defined groove between the lateral masses and the uterus, points invariably to pelvic inflammatory deposit in the tubes and ovaries. The patient may

*Read before the Med. Soc. of the County of Erie.

suffer intensely on one side, and the disease be present on the other, hence, both sides should be examined.

Again, there may be exceedingly marked disease, and the ovarian and tubal complications small. Here it is well to remember that intestinal complications are often at the bottom of the size of the tumor, so that when adhesions are all freed, the mass that is to be removed is insignificant in its appearance, though examination by floating the mass will disclose the multiplicity of the adhesions and their density. Tubercular variety of inflammation is often puzzling and should receive careful attention.

In all forms of inflammation under consideration, the tendency is toward deposits in multiple locations. This is due both to inflammatory strictures in the tube and to the different structures encountered in the inflammatory process. Hence it is necessary to deal with all pelvic deposits as we know they must exist anatomically, taking into consideration their cause and the structures involved, and not treat them as hypothetical quantities under uncertain processes. If we consider the suppurating, inflamed tube as an offending organ, quite as much as the retained placenta, we cannot go astray in its treatment. It is just as logical to treat the remaining *débris* of labor as a benign and inoffensive residue, as to look at this internal disease as harmless; indeed, it is much more rational, for the one has some chance of escape, the other none.

ON THE TORSION OF ARTERIES.

In connection with operations for excision of tumors, and other excisions of a like character, Jonathan Hutchinson remarks as follows: "I may mention that for many years I have quite ceased to use any other means for the arrest of arterial bleeding than torsion. In excision of the breast, for instance, I do not think that I have during the last fifteen years ever used a ligature. The torsion is always effected by a pair of Well's clamp forceps, now in such universal employment. I am always extremely careful to close all vessels, keeping the wound exposed for a considerable time for that purpose. Very seldom, indeed, have I encountered any secondary hemorrhage." —*Columbus Med. Jour.*

PLAIN TALKS ABOUT EARLY DIAGNOSIS, AND EARLY OPERATION IN CERTAIN INTRA-PELVIC DISEASES OF WOMEN.*

By CHAS. A. L. REED, M. D.,
CINCINNATI, OHIO.

The author opens this subject with the important remark that, "the chief cause of mortality in abdominal and pelvic surgery may be epitomized in the word 'delay.'" The patients themselves may be often to blame, either through undue modesty or fear instilled by friends or physicians who misapprehend the true status of pelvic surgery. What is needed to remedy this evil is to have the actual results of special workers in this field of surgery published and republished, until the general profession begins to comprehend what can be done for the relief of their unfortunate patients. It should be held up that the mortality of abdominal section in skilled hands is under three per cent, and that with all operators, results improve just in proportion as they get their cases early and as their experience increases. The doctor further emphasizes that he insists upon examination only in the presence of persistent symptoms pointing to disease in the pelvis; the word "persistent" being significant in that it implies that the conservative measures of treatment have first been tried; he does not operate upon twenty-five per cent. of the cases that come to him for that purpose, and never selects cases. He feels certain his colleagues are equally discriminating.

In making examinations he does not agree with the writer in Mann's system of gynæcology, that inspection of the external genitalia is as indelicate as unnecessary, and should never be practiced in the absence of some special indication. He condemns the Fergusson's cylindrical speculum, blaming the tortures induced by this instrument, for some cases never passing beyond their first examination. The sound, to-day the opprobrium of the gynecic outfit, often produces great mischief, never aids in diagnosis should be discarded entirely. All grotesque and

*Read before the Med. Soc. of Erie County, June 14, 1892.

needless postures frequently pictured in the books are condemned.

For an operator of experience, whose touch is cultured, it is not necessary to place the patient in any other than the recumbent posture with knees flexed. A speculum has no place in the diagnosis of conditions above the pelvic diaphragm; instrumental examination of the uterine cavity is always hazardous; should be employed only in exceptional cases, and then only under the most scrupulous asceptic precautions.

Tumefaction above either fornix with or without fixation, generally means irreparable organic mischief, which, if not already furnishing a nidus for pus, offers at least an inviting field for suppuration. When this condition exists in connection with a history of previous miscarriages, dirty accouchements, intrauterine thickenings, and electrical treatments, but particularly when a distinct history is given of one or more attacks of pelvic peritonitis, which, however, may not have been of a severe type, the conclusion is simply irresistible that the case belongs in the surgical category, and that operation should be advised and practiced at the earliest possible moment.

RETENTION TUMORS.

Retention tumors in the abdomen formed the subject of some remarks by Jonathan Hutchinson in the *Archives of Surgery*. He described several cases of remarkable retention of fæces in children and stated that this condition is the common cause of pot belly. There is no obvious retention in these cases he says, the bowels perhaps moving regularly or even incontinently, producing precisely the same condition of things which, when it occurs to the bladder, is described as "retention with incontinence." He says that he once tapped a woman's belly and drew off urine where he evidently expected to find ascites. For the recognition of abdominal retention tumors he offers the following memoranda:

(1) The distension, although enormous, is usually quite painless.

(2) The retention is never absolute, but only residual. There is always overflow.

(3) The patient never assists the surgeon, but rather misleads him, insisting that there is free relief of bowels and bladder.—*Lancet.*

THE PRACTITIONER'S ANATOMY OF THE RESPIRATORY PASSAGES AS APPLIED TO INTUBATION, LARYNGOTOMY, TRACHEOTOMY AND BRONCHOTOMY.

A paper with this title was read by Dr. James E. Kelley, (Section Ped., N. Y. Academy of Med., *Virginia Med. Monthly*, vol. xviii, No. ii, 1892) and illustrated by charts, diagrams and elaborate fresh dissections. Especial attention was given to the mechanical view of the subject, as being of far more value than the vast amount of detail to which the student is treated without a clue to its practical application.

The anatomy of the child varies but little from that of the adult. The *thymus* is the only structure that causes important modification in the region under consideration. In operating low down in the pre-tracheal space in young children, it causes serious obstruction. It varies greatly in shape, and is subject to numerous anomalies. It usually forms a body extending entirely across the space between the sterno-mastoid muscles. Two processes pass upward in close apposition to the tracheal fascia and terminate within half an inch of the isthmus of the thyroid to which they are attached by two ligamentous bands. Hence, but a limited portion of the trachea is uncovered and available for operation below the isthmus of the thyroid. This latter body is occasionally absent, and sometimes in an abnormal position—conditions which may be very puzzling to the operator.

It is impossible to make a dissection in this region as neatly and almost as bloodlessly in the living subject as in the cadaver. This is especially true in young patients. The more closely an operation resembles a dissection, the more satisfactory it is to the surgeon, and safer for the patient. Hap-hazard surgery is a lottery, in which fools play for their patients' lives.

In considering the anatomy of the region, the relations of the osseous structure are of much importance. The posterior surface of the larynx aud trachea corresponds and adapts itself very closely to the contour surface of the spinal column. The œsophagus and lower portion of the pharynx, which occupy but little space,

are the only structures between the trachea and the vertebræ. Thus the laryngo-tracheal tube, passing downward and backward, intersects the place of the sterno-mastoid muscles. This is a point of much practical importance in *low tracheotomy.*

Laryngotomy is an operation so undesirable that it merits but little attention. It opens the larynx just below the rima glottidis, where the canal is narrowed into a wedge, the thin edge being anterior. The cartilage is rigid, and of such low vitality, that the injury resulting from the separation, and the introduction of a tube, is liable to be followed by necrosis. There being but little subcutaneous tissue, an unsightly scar usually results, which lies so high that it cannot be concealed.

The hybrid operation, *laryngo-tracheotomy*, is unjustifiable, as it destroys the continuity of the cricoid cartilage upon which the larynx largely depends for its shape. All the external operations upon the respiratory passages are performed between the hyoid bone and the sternum, in the mesial line, between the sterno-hyoid and the sterno-thyroid muscles, but tracheotomy alone being done *below* the isthmus of the thyroid. Not an important structure lies above the isthmus, but below there are numerous important vessels. This lower space is analogous to a space just above the pubis. Two spaces are formed by two distinct layers of fascia, which are fused above the isthmus to form a single fascia. In the superficial space, are the anterior and transverse jugular veins, and a few small arteries. In the deep space are the left innominate, the inferior thyroid, and a venous plexus.

Much interest has, of late, been aroused in the operation of *bronchotomy* for the removal of a foreign body from a bronchus. The author is inclined to think that the operation is justifiable, and that there is no insuperable anatomical difficulty in the way. The cordate shape of the chest places the root of the lung much nearer the surface than is usually supposed. A vertical incision should be made though two or more costal cartilages, or though the ribs just internal to the mammary glands. This readily brings the structures into view, the relations of which are very close and intricate. While the mechanical difficulties are great, a still more important question is the possible effects of interference with the heart and great vessels. Upon this point little or nothing is known. While *intubation* requires but little anatomical knowledge there are certain points which are quite essential. The point of the tube may enter numerous depressions and fossæ, preventing its introduction. The first are the glosso- epiglottic fossæ, separated from each other by the frenum of the epiglottis. The glottis itself is situated in the midst of soft, yielding tissues, which are easily indented.

A slight depression exists just above the false vocal cords which may readily catch the tube. The lateral ventricles of the larnyx are, however, the source of most serious trouble. These ventricles lie upon either side between the true and false vocal cords. The true cords especially in phonation or stridor approach more closely to the mesial line than the false, thus forming a cavity with a concave floor, in which the end of the tube is very easily entangled. Just behind the glottis, and separated from it by the arytenoid bodies is the lower portion of the pharynx, the most capacious snare set for the operator, and the one into which he most frequently falls. The whole area in the infant is readily covered with the tip of the index finger. The surface of the glottis is moreover, very oblique to the pharynx, so that the tube easily glides backward into that cavity. Unless the true cords are accurately reached, the point of the tube is deflected into the capacious and yielding ventricle.

The operation can, therefore, be performed with facility only when the tube is held parallel with the mesial line of the body, but obliquely to the long axis of the rima, and with the point directed toward the inferior margin of the cricoid cartilage. This can be effected by introducing the instrument into the mouth with the handle over the bicuspid tooth, with the point of the tube directed forward toward the glottis. The common error is thus avoided of passing over the epiglottis. Owing to the more extended area opposed to the ventricles, the tube is not so liable to be caught in them. As the surface of the larynx containing the glottis does not look upward, but almost directly backward, the handle of the introducer should be elevated to bring the point of the tube forward.

In young children the epiglottis is sometimes so soft and small as to be found with great difficulty. Pass the finger low

into the pharynx until the resisting cricoid cartilage is felt, on the upper margin of which are situated two movable nodules, the arytenoid cartilages. Immediately above, and in front of these in the mesial line, is the epiglottis.

Dr. H. D. Chapin said that he had performed tracheotomy several times upon children under two years, and had been surprised at the extreme obliquity of the trachea which caused it to lie at the great depth at the lower portion. This was a strong argument in favor of intubation in young children instead of tracheotomy.

Dr. Kelly remarked that he believed that the narrowest point in the respiratory tract was at the true vocal cords.

The Chairman referred to experiments by Dr. O'Dwyer and himself, which proved that the *narrowest point* was not at the cords, but at the cricoid cartilage. An intubation tube could frequently be drawn, with the use of but little force, downward past the cords, which could not be made to pass below the cricoid. A tube much smaller than the prescribed size might drop below the cords, but would not pass below the cricoid into the trachea. The most recent modificaton of the tube approved by Dr. O'Dwyer, consisted in making the lower end bulbous in shape and equal in size to the largest part of the tube. This would prevent its entering the ventricle of the larynx, a very frequent source of failure.

Dr. Kelly replied that if the tube were turned to the side as far as possible during the introduction, it would bring the long diameter in position to act as effectually as the bulb described. The posterior operation of bronchotomy was impossible because of the closer apposition and less yielding character of the ribs requiring extensive resection. The trunk of the intercostal vessels were also met posteriorly instead of the branches.—*Pacific Med. Jr.*

TREATMENT FOR SWEATING HANDS.

Take of tincture of belladona, 1 drachm, eau de cologne, 1 ounce. Mix. Pour a few drops of glycerine into the palm of the hand, then add to it an equal quantitity of the above mixture, then rub the hands together strongly. They should have been well washed in soft water and thoroughly dried previous to the application.—*American Analyst*, Oct. 15, 1892.

SURGICAL TREATMENT OF PERITONITIS.

Dr. C. J. Cullingworth read before the Obstetrical Society of London a paper based on fifty observations of his own, in favor of surgical intervention in certain cases of pelvic peritonitis. The cases include the whole of the author's experience to February, 1891. Pelvic suppuration was present in thirty cases, or 60 per cent. It occurred in the fallopian tube alone in thirteen cases, in the ovary in seven cases (in six of which tube and ovary were in direct communication), while in the remaining four cases the seat of suppuration was either not precisely determined or did not involve either the tube or the ovary. There was strong presumptive evidence of gonorrhœa in a large proportion of the cases, and in four cases the proof seemed complete. Nine of the cases died, a mortality of 18 per cent. Seven of the deaths were due to peritonitis, probably septic, one to acute nephritis, and one to collapse on the eleventh day Of the fatal cases one was tubercular disease of the tubes, two were purulent salpingitis, one was double salpingitis with old hæmorrhage, two were suppurating tubo-ovarian cysts, one was retro-peritoneal suppurating cyst, two were old peritonitis with serous cysts of broad ligament. The mortality sensibly diminished as he acquired experience. Hæmorrhage to a greater or less extent, existed in twelve of the thirty-two cases of salpingitis. In five cases there was amenorrhœa, in three dysmenorrhœa, whilst in twelve the menstrual function was undisturbed. In sixteen cases the removal of the appendages was complete, in twenty-three partial. Of the former, fifteen recovered; of the latter, seventeen. The peritoneum was flushed in twenty-two cases, of which eighteen recovered. Drainage was employed in forty-seven out of the fifty cases. In two cases a fæcal fistula formed, which in each instance healed spontaneously. In five cases the patients complained some time after the operation of more or less persistent pain. A sinus existed in six of the cases when the patient left the hospital: in two of these it had not healed when the patient was last seen. In four cases a hernia had occured in the line of incision. He particularly called attention to the unreliability of the temperature as a sign of the existence of pelvic suppuration, the

temperature before operation having been absolutely normal in twelve of the thirty cases in which suppuration was present. He suggested the following conclusions as the outcome of his experience. 1. Recurrent attacks of pelvic peritonitis in the female ought always to lead to a strong suspicion of the existence of chronic disease of the uterine appendages, and to careful bimanual examination. 2. Purulent collections in the pelvis are particularly apt to set up recurrent peritonitis, and are more common than is at first supposed. 3. Where distinct swellings are found in the posterior quarters of the pelvis, in connection with recurrent attacks of pelvic peritonitis, surgical relief is usually indicated, and generally speaking, the sooner such relief is afforded the better. 4. Purulent inflammation of the mucous membrane of the fallopian tube differs from purulent inflammation of other mucous membranes in the absence, owing to the anatomical situation of the fallopian tubes, of a natural outlet for the pus. A very slight amount of swelling of the mucous membrane suffices to block the tube at its uterine end, and if pus be present in the tube, it must then either remain pent up in the tube, or be poured out through the fimbriated end into the peritoneum in either case becoming a source of danger. 5. Salpingitis being a painless affection, the wall of a pyosalpinx may be on the point of perforation before an acute attack of peritonitis gives warning of the presence of serious disease. 6. It is safer to attack cases of pelvic suppuration from above than from below. 7. Suppurating tubo-ovarian cysts are usually the result of ulceration on the tubal side of the adhesion between tube and ovary, but in exceptional cases results from ulceration on the ovarian side. The immediate results are more satisfactory after complete than after partial operation. 9. One of the chief risks in the operation for the separation and removal of inflamed tubes is the liability to mistake thickened and adherent intestine for diseased tube. The way to avoid error is to trace the tube from its uterine end outwards. 10. The exceptional instance in which pain persists after operation for gross lesions of the uterine appendages are generally to be explained either by omental or intestinal adhesions, or by the co-existence with the actual disease of a neurotic condition, of which the pelvic pain is a mere local expression. 11. Tubal disease in the virgin is generally, if not always, tubercular. 12. Hydrosalpinx, in the great majority of cases, is merely a form of retention-cyst due to occlusion of the distal end of the tube from without. 13. Simple collections of serum, both large and small are apt to form beneath the peritoneum covering the tube and broad ligament in chronic cases of pelvic inflammation especially in those of very long standing. Probably the best treatment of these cysts, after exposing them and making certain of the diagnosis by abdominal section, is simple puncture and evacuation, the risk of removing being, in the author's experience, out of proportion to their importance. 14. Hæmatosalpinx, though no doubt due, in the majority of cases, to tubal gestation with apoplexy of the ovum, is sometimes an incident in the course of a chronic salpingitis. In these exceptional cases the walls of the distended tube, instead of being attenuated by the distension, as Bland Sutton has shown them to be in tubal gestation, are thickened by inflammatory deposits.

The paper was illustrated by a number of drawings and photographs of the appearances in certain of the cases.

The discussion was adjourned until the next meeting.

IODOFORM.

Following are a few of the numerous applications of iodoform. In the obstinate, chronic enlargement of tonsils, so common in our changeable climate, the writer has derived good results from iodoform in pill of ½ or 1 grain, three times a day, persisted in till patient declares throat is well. In glandular enlargements, particularly of a strumous nature, an ointment —20 to 60 grains to ounce of lard, vaselin, or lanolin— will prove a prompt and effective sorbefacient

It has been found useful when applied to enlarged prostrate gland. A professional friend informs me that a prostate enlargement with stricture, that had resisted all other treatment, yielded to the local application of the drug. Writer has seen a small ulcer of leg to which a 20-per-cent. ointment was applied, rapidly fill up from bottom with healthy granulation. Large burnt surfaces have healed and cicatrized without contraction under its benign influence.—*American Therapist.*

Selected Formulæ.

BURNS.

Von Bardeleben recommends for burns of moderate severity the use of a powder of equal parts of subnitrate of bismuth and powdered starch. The burns are thoroughly cleansed, then washed with a three per cent. carbolic, or three per cent. salicylic acid solution. The blisters that are present are then removed under antiseptic precautions and the above powder then thoroughly applied. This is covered with layers of cotton, which are removed as they become saturated with the secretions, except the one next the wound. This dressing may remain undisturbed for one to two weeks or even a month. In most cases, pain disappears a few hours after applying the bismuth. In burns of the face the writer uses the powder with no other dressing.—*Boston Med. and Surg. Jour.*

INHALATION IN WHOOPING COUGH.

℞
Thymolis.....gr. xx.
Acid carbolicis
Ol. sassafragis
Ol. eucalyptus ..... āā..f ʒij.
Picis liquidæ
Ol. terebinthinæ
Ætheris.....f ʒiv.
Alcoholis, q. s. ad.....f ʒiij.

M. Sig.—Put about 30 drops upon a pad of such size as to be conveniently hung around the child's neck, renewing the application every two or three hours.

In severe cases the inhalation treatment is supplemented by the internal administration of:

℞
Acid carbolic.....gr. iij.
Sodii bromid.....gr. lx.
Tinct. belladonnæ.....gtt. xx.
Glycerinæ.....f ʒiij.
Aquæ, q. s .....f ʒij.

M. Sig.—f ʒij occasionally for a child of 3 or 4 years of age.

—*Jour. Amer. Med. Assn.*

GLYCERIN SUPPOSITORIES.

℞
Sodium carbonate ..... 40 grains.
Stearic acid..... 80 "
Glycerin.....1,080 "

Sig.—Dissolve the sodium carbonate in the glycerin, add the stearic acid, heat carefully (preferably by the use of a water bath) until effervescence ceases; the solution is then poured into a suppository mold to make 12 suppositories.

There is no necessity for cooling the molds with ice, although there is no objection to this in warm weather. As each suppository contains about 90 per cent. of glycerin, they must be protected from the action of moist air, which has a tendency to liquefy them. Several expedients are resorted to. Each one may be wrapped in tinfoil or quickly dipped in melted paraffin; or each one enclosed in a small glass vial without a shoulder and made for the purpose of holding one suppository.—*Pharmaceutical Record.*

COUGH MIXTURE.

℞
Syr. tolu
Syr. pruni virg.
Tr. hyoscyami ..... āā..ʒi.
Spts. eth. co.
Aquæ

M. Sig.—A teaspoonful every hour.

—*Janeway.*

For the treatment of the reflex cough accompanying catarrhal sore throat, there is no remedy so effective as a spray of the following, which may also be used as a gargle:

℞
Acidi carbolici.....ʒi.
Pulv. sodii bor.....ʒi.
Cocainæ hychochlor.....grs. xii.
Glycerini purif.....ʒss.
Aquæ rosæ.....ad ʒxii.

Sig.—To be used as directed.

—*Ontario Med. Jour.*, Oct., 1892.

Dr. T. J. Mays (*Pitts. Med. Review*) suggests the following as a stimulant to the appetite in Pulmonary Consumption:—

℞
Acid. phosphoric. dilut.
Acid. muriatic. dilut.
Acid. sulphuric. dilut. ..... āā..f ʒss
Tinct. ferri chloridi

M. Sig.—Thirty drops in a half glass of cold sweetened water during meals

—*College and Clin. Rec.*, Oct., 1892.

THE "SUN" CHOLERA CURE.

Take equal parts of tincture of opium, tincture of rhubarb, tincture of cayenne, spirits of camphor, essence of peppermint.

Mix well together. Dose: fifteen to thirty drops in water; to be repeated in fifteen or twenty minutes if necessary.

This is the original formula for the *Sun* cholera Cure. It was given to the *Sun* in the "cholera year" 1849 by George W. Busteed, then and now a practicing pharmacist in this city. It was published daily in the *Sun* during the summer of that year. It was published at intervals for several years, and again daily during the "cholera years," 1855 and 1866, and has been printed in the *Sun* probably 1,000 times since it first appeared.

The *Sun* cholera cure has been adopted into the United States Pharmacopœia, and is a medicine approved and valued by every medical man in the country.—*American Analyst,* Oct. 1, 1892.

THE

Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS:

Care P. O. Box 843, Philadelphia

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, NOVEMBER 5TH, 1892.

ANTIVIVISECTION.

For a number of years, in England and America, an antivivisection propaganda has from time to time attracted public attention.

Popular sympathy is easily aroused for any reform that is not aimed at popular crimes or vices. Public opinion indignantly resents abstract wrong or evil deeds in somebody else, especially when the heart is wrung by tales of "inhuman" and "diabolical" cruelties sobbed by women with streaming eyes or whispered with bated breath by men.

But justice is likewise an element of an enlightened people and after emotion has been gratified a desire is felt to hear what the other side may have to say. With sincerity which events have shown to be more apparent than real and with imagination fired by enthusiasm hot to melt the bowels of compassion, Zoophilists have prosecuted a campaign against experimental research.

With sincerity more real than apparent the energy expended to save a rabbit from inoculation would raise a fallen woman; imagination tempered with common sense would not perceive more horror in the breathing of an anæsthetized dog than in the wail of a starving child. Fervent enthusiasm might be used to elevate the "submerged tenth," and with better results than when directed to the distortion and hindrance of efforts to aid humanity which time and experience have vindicated.

But the zeal of the anti-vivisectionists has over-balanced the wisdom, and enthusiasm far out-stripped the knowledge.

In this country at a recent congress the utmost the *zoophilistines* could accomplish was the passage of a compromise resolution in effect condemning all *unnecessary* experiments on living animals.

In England, speaking of the recent exposé of the anti-researchers, the *British Medical Journal* says:

> The anti-research controversy opened at the Church Congress and which at one time threatened to extend itself to portentous proportions happily seems now likely to come to an early conclusion; and that in the fashion which must be wholly satisfactory to the profession since physiological experiment of the kind is absolutely necessary for the progress of human knowledge and the alleviation of human suffering. Miss Cobbe has fairly turned tail and quits the field. She does so under an excuse which very well accords with the system of tactics which she has throughout adopted in this matter. For a series of years, and in a variety of publications, this lady brought a series of vile accusations against the most eminent, humane, and accomplished physicians, surgeons, and scientists of the day, having charged men of the rank, class, and character of Lister, Burdon Sanderson, Lauder Brunton, Ferrier, Horsley and their supporters and defenders Paget, Clark, Humphry, Wilks—and in fact the whole medical profession with a few insignificant exceptions she has charged; the one with performing and the other with countenancing and defending, acts which she so

describes as to induce her ally in the attack—Canon Wilberforce—to describe them as "inhuman devils," and the Bishop of Manchester to characterize them as "diabolical." She now withdraws from the contest which she has provoked, because she finds it intolerable to be told, with abundant proof adduced, that her quotations are false; that she has deliberately suppressed the fact that in the very operations to which she refers morphine and chloroform were administered; and that she has repeatedly and fraudulently omitted to state that vital fact.

When her falsehoods are plainly exposed and she is challenged in very distinct language to bring her statements to proof—statements she has not attempted to prove and knows she cannot prove—to withdraw them in sackcloth and ashes, she replies through Dr. Berdoe that her feelings are too much hurt to allow her to take the only course which truth and honor and justice demand—that of humble, open, and lifelong repentance and humiliation.

It is, of course, open to Miss Cobbe to throw her literary assistant into the ditch, and to take for herself the credit of all the high moral indignation with which she fills her signed preface; and thus to leave her literary assistant to bear the dishonor of having deliberately suppressed the vital fact that in the very operations which are quoted in inverted commas as evidences of horrible cruelty, the animals were under the influence of chloroform or of chloroform and morphine. It is of little avail for her to do this, because in her preface she takes upon herself the whole responsibility of asserting that in every instance cited the presence or absence of anæsthetics has been carefully noted. If the fault, nay, the crime, of this suppression of truth on which such an edifice of deliberate, and persistent calumny has been built, be not with her but wholly with her assistant, let her at least express her profound regret at the deceit which has been practiced on her, and at having been led, in that case, unwittingly to have done a most cruel wrong. Thus far she has done nothing of the sort. She is a professed exponent of the laws or Veracity, with a big V, and no doubt the list of eminent persons who have been misguided by her, and induced to allow their names to be paraded as patrons of the Antivivisection Society, has relied upon her Veracity, and taken it to mean truthfulness. Let Lord Coleridge, Mr. Stansfeld, Mr. John Morley, the Bishops of Southwell, Liverpool, Wakefield, Carlisle, in addition to the Bishop of Manchester and Bishop Barry, let them one and all, come forward now and say honestly what they think of this exhibition of Unveracity. They, who are not ladies, need not shrink back because a spade is called a spade; and if this thing is, as Professor Horseley had shown it to be, a falsehood of the worst kind, they need not be deterred from expressing their opinion, even though a "Saxon monosyllable" has been used to characterize the falsehood.

Book Reviews.

Gynecology, A Manual for Students and Practitioners, by G. W. Bratenahl, M. D., Assistant in Gynecology, Vanderbilt Clinic, New York, and Sinclair Tousey, M. D., Assistant Surgeon, Out-patient Department, Roosevelt Hospital, New York. Lea Bros. & Co., Philadelphia. Student's Quiz Series. $1.00.

The authors have discussed the diseases of the female generative organs in the order of the anatomical position of the latter, beginning with the vulva; closely following the teachings of Emmet, Munde and Thomas. As a rule the symptoms of the different diseases and the various operations are clearly and concisely stated, with the exception of Emmet's operation for lacerated perineum, where the amount of denudation necessary and the manner of passing the sutures are not plain.

Some old fashioned notions still cling to the book, however, since pelvic cellulitis is gravely discussed and a differential diagnosis given by which the troubled gynecologist or busy practitioner may decide whether the case in point is one of pelvic peritonitis or cellulitis. The sound is still used as a diagnostic instrument though the contra-indications to its use are carefully stated. We notice, however, one glaring contradiction. On page 30 we are told that the sound is contra-indicated in "any peri-uterine inflammatory condition, or tenderness of the uterus and appendages;" and on page 32 we read that "it should not be used to replace a malpositioned uterus or to test its ability," yet in discussing flexions, we find under anti-flexion (page105) that "the diagnosis consists in the establishment of the stability of the flexion. This may be determined by the use of the sound." That "anteflexion might be mistaken for anterior inflammatory and cellulitic exudations. The sound passed into the uterine cavity will determine these conditions." Probably it will determine these, and also a subsequent section should its incautious use light up an old standing pelvic inflammation or tubal disease. Again, under

retro-flexion, we are told that the sound may be employed to correct the mal-position "when the uterus is too sensitive to be pushed upward by the fingers, but is always more or less unsafe." Surely this is an oversight which will be corrected in later editions.

The dangers of curetting the uterus in the presence of tubal trouble are clearly shown and also that of cervical dilators. In speaking of securing the pedicle in removal of diseased tubes and ovaries, we are told that it is best done by ligating with the Staffordshire knot. In view of the fact that this knot has proven treacherous so often, it would seem better to us that a simple figure of eight or chain ligature be advised.

Extra-uterine pregnancy is fairly well treated and immediate removal of a ruptured tubal gestation advised. In unruptured cases the treatment of delay and doubt by means of electricity is urged. Electricity is advised for acute inflammation, adhesions and exudates, and its use in gynecology thus summed up: "In a certain proportion of cases in the above classes the results are excellent; in other cases the results are discouraging. While not a panacea, it is still a legitimate and desirable means of treatment in gynecological diseases." The contra-indications to its use and its dangers receive no mention and we are led to believe that it is harmless.

The volume is what it pretends to be —a students' quiz-compend, and may be useful as such, a brief remembrancer to the rusty practitioner.

BOOKS RECEIVED.

Diseases of the Lungs, Heart, and Kidneys. By N. S. Davis, Jr., A. M., M. D., Professor of Principles and Practice of Medicine, Chicago Medical College; Physician to Mercy Hospital; Member of the American Medical Association, Illinois State Medical Society, Chicago Medical Society, Chicago Academy of Sciences, Illinois State Microscopical Society; Fellow of the American Academy of Medicine; Author of "Consumption, How to Prevent it and How to Live with it," etc. No. 14 *in the Physicians' and Students' Ready-Reference Series.* In one neat 12mo volume of 359 pages, Extra Cloth, $1.25 net. Philadelphia: The F. A. Davis Co. 1231 Filbert Street.

Tuberculosis of Bones and Joints. By N. Senn, M. D., Ph. D., Professor of Practice of Surgery in Rush Medical College; Professor of Surgery in the Chicago Polyclinic; Attending Surgeon Presbyterian Hospital; Surgeon-in Chief St. Joseph's Hospital; President of the American Surgical Association; President of the Association of Military Surgeons of the National Guard of the United States; Permanent Members of the German Congress of Surgeons, etc. Illustrated with 107 Engravings (seven of them colored). In one handsome Royal Octavo Volume, 520 pages. Extra Cloth, $4.00 net; Sheep, $5.00 net, Half-Russia, $5.00 net. Philadelphia: The F. A. Davis Co., Publishers, 1231 Filbert Street.

Hygiene of the Sick-room. A book for nurses and others. By William Buckingham Canfield, A. M., M. D. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street. $1.50.

Diseases of Women. A manual of non-surgical gynecology designed especially for the use of students and general practitioners. By F. H. Davenport, A. B., M. D. Second edition, revised and enlarged. Philadelphia: Lea Brothers & Co. 1892.

A Manual of Physics. Being an introduction to the study of physical science. Designed for the use of university students. By William Peddie, D. Sc., F. R. S. E. New York: P. P. Putnam's Sons. London: Bailliere, Tindall & Cox, 1892. $2.50.

Periscope.

THERAPEUTICS.

ON THE TREATMENT OF GAUCHER IN RELATION TO DIPHTHERITIC PARALYSIS.—ON THE CONTAGION OF ANIMAL DIPHTHERIA TO MAN.

Dubousquet-Laborderie (*Jour. de Méd. de Paris*, 1891, iii., 510.) writes: Since 1884, Gaucher has treated or seen in consultation eighty-five cases of diphtheria. Among these he has seen but once a case of paralysis. Dubousquet-Laborderie, since 1884, has taken care of 127 cases of diphtheria, among which he observed only three cases of paralysis. All three cases were light. These 212 cases are grouped without distinction, but among the number, several have been diphtheria of very severe type. This showing seems to militate in favor of the efficiency of the treatment advocated by Dr. Gaucher—a treatment which arrests on the spot the rapid development of the microbes, and prevents the toxic products from being carried to the nervous centers.

Since the work of the commission appointed by the Academy of Medicine at the beginning of the century, to study in Cologne the contagiousness of the diphtheria of fowls for man, many reports have come to confirm the conclusions of the commission. Klebs records himself for the contagion. But this idea of contagion assumes for premises the identity of the

nature of the diphtheria of human kind and of animals, while the bacteriologists have not generally ratified this, for the reason that the microbes do not resemble each other. The researches of the laboratories can hardly weaken the clinical fact in the matter, however. Loeffler has stated that culture of bacilli from diphtheritic pigeons inoculated upon other pigeons, communicated to them the disease which became promptly general, while the same cultures produced in chickens only small lenticular ulcerations at the point inoculated, without any general infection. From this he concluded that the diphtheria of pigeons and that of chickens were not identical. Some observations tend to show that what is called the quinsy of animals may be equally contagious: Two children assist at the removal of the hide of a horse dead of quinsy; both children die of diphtheria, or which there was no other case in the neighborhood. An adult man removes the hide from a donkey which had died of quinsy, and dies himself of diphtheria. No other case of diphtheria in the region. In another instance, a large number of fowls died of diphtheria, several of which were devoured by pigs. One of the pigs having died of quinsy, its owner pierces the trachea in the presence of a little girl of five years of age. This child succumbs to diphtheria, her sister is attacked also, but recovers. The place where this family lived was thirty kilometers from the nearest settlement, and no communication, direct or indirect, had never been noted in the place.

SEVERE ACCIDENTS OF IODISM.

An unsigned paper in *La Semaine Mèdicale*, 1892, No. 5, p. xviii, gives an excellent account of our present knowledge upon this subject. Œdema of the glottis, of the same kind as serous infiltration of the eyelids, has easily caused death. In instances when at death the body has been covered by a pemphigus, a nephritis has generally been found. At times, even when death has resulted from œdema of the glottis, this renal condition has not been found. Curiously enough the doses which have been followed by œdema of the glottis have been, in general, small (six and one-half grains, Fournier). Attempts have been made to avoid such symptoms as œdema, coryza, headache, conjunctivitis, and epiphora, by its exhibition in milk, or the administration with belladonna, or bromide of potash. Following the method of Röhmann and Malachowski, it is believed that the bicarbonate of soda will prevent these untoward symptoms, by rendering the blood more alkaline, which will hinder the setting free of the iodine of the iodide of potash. It is given in two daily doses to the amount of seventy to ninety grains. In all cases the integrity of the renal filter should be assured, although even in actual renal disease, as chronic interstitial nephritis, we may receive great benefit from this drug. While disease of these organs is not an absolute contra-indication, yet it should be administered in the usual (not small) doses, and at the outset, preferably with the bicarbonate of soda.—*Amer. Jour. Med. Sci.*

INTUBATION IN TUBERCULOUS LARYNGITIS.

Hopkins (*N. Y. Med. Journ.*,) briefly mentions all the cases known to him in which intubation has been performed for the relief of dyspnœa due to tuberculous laryngitis, namely, three cases by Massei, who stated that stenosis might be got to yield in a surprisingly short space of time; a case by Dillon Brown, and another by Cox, both performed to procure euthanasia; and one case of his own. This was a woman, aged 39; after some months of gradual encroachment on the lumen of the larynx by the tuberculous process, she began to suffer from suffocative attacks, and when called to her Hopkins found that the dyspnœa was extreme, preventing sleep and swallowing. The rima was narrowed and the cords fixed owing to a mass of thickening in the posterior commissure. After failure with a large (largest for child of twelve) O'Dwyer's tube, a size smaller was passed after overcoming much resistance. The relief was immediate and considerable. The tube was expelled during a fit of coughing, but the relief to the dyspnœa persisted. Examination of the larynx showed that this was due to a portion of the mass in the posterior commissure having been torn away; some cicatricial process appears to have occurred later, still further enlarging the rima. She had an attack of dysphagia twenty-four hours after the intubation, and expectoration became blood-stained.

The condition of the patient, however, was materially improved; she regained appetite, was able to go out, and for the remainder of her life—about ten weeks—she had no recurrence of the dyspnœa.

Creasote, in doses of 4-19 drops daily, has produced good results in the hands of Dr. T. Valentine in *diabetes mellitus.*

Hot water, by enema, has been warmly recommended as a hæmostatic in *post-partum hæmorrhage*, or in threatened *abortion.*

Camphoric acid in 2 per cent. solution, applied on a cotton tampon, is reported as affording prompt and permanent relief in *acute coryza.*

Salicylic acid, while formerly condemned as a *diuretic* by most authorities, is now warmly recommended as such.

Euphorbia-pilulifera tincture (15 drops every two hours) is lauded as being very efficacious in all forms of acute "*cold in the head.*"

Calcium sulphide in 1-20-grain doses is reported to prevent the formation of *boils,* and in ¼-grain doses to hasten their suppuration.

Ammonium acetate, in 15-grain doses, is reported to have given excellent results in *scarlatina.—Merck's Bulletin.*

POISONING BY ANTIFEBRIN.

During the last influenza epidemic in Sweden, a great many cases of poisoning by antifebrin were observed. This was due to a very prevalent, careless use of the drug without a doctor's prescription. Although somewhat severe symptoms were observed in many cases, all ended in recovery. In one case, reported by Dr. W. Warfring, a man aged thirty-five took two drachms of antifebrin. The principal symptoms observed in the order of their occurrence were a sense of fatigue and a feeling of weight in the head, coming on in five minutes; soon followed by a sensation of black and red clouds before the eyes; then sleep, from which the patient was easily aroused. On attempting to rise, he appeared like one drunk, fell down and became unconscious. This was soon followed by a comatose condition, cyanosis, relaxed muscles, cold hands and feet, lowering of temperature, respiration and pulse. These latter improved after hypodermic injections of camphor and ether, but the comatose state continued for sixteen hours. The symptoms on the next day were frontal headache and cyanosis. The urine was clear, deep-colored, and contained much indican, otherwise normal. Some cyanosis remained on the third day, and the urine still contained an excess of indican. Another case was that of a girl of fifteen, who took nearly half an ounce of antifebrin. In a quarter of an hour her whole body became hot and perspiring. Vertigo, impairment of sight, and unconsciousness followed. This last condition continued for seven hours and a half. There was vomiting. Coma was not so deep as in the other case; cyanosis was well marked; pupils slightly contracted, temperature slightly subnormal. This patient recovered more speedily than the other, probably because the stomach was washed out within an hour after the antifebrin was taken. Similar, though not so severe, symptoms have been observed in other cases; the doses taken being, in one case, two scruples on two consecutive days, in two others two teaspoonfuls each, in one dose.—*Boston Med. and Surg. Jr.*

CRANBERRIES IN RHEUMATISM.

Dr. J. Hermann (*Wiener med. Presse*) speaks very highly of cranberries in the treatment of rheumatism, both acute and chronic. This berry has long been employed in popular medicine as an antirheumatic remedy. The writer has a case of chronic rheumatism which had resisted the salicylates and all the ordinary remedies. The decoction of cranberries was given, and after a few weeks a striking improvement set in, which was followed by a complete recovery in two months. The remedy was also tried in nine other cases, of which six were acute and three chronic. All these had been treated in vain with the salicylates and the various preparations of iodine, as well as with warm baths. The berry was employed in the form of a decoction, thirty to sixty grams of the entire plant—leaves, stalk and root—to 180 grams of water. This is drunk in twenty-four hours. The duration of

of the treatment was from one to three months. Out of the nine patients, seven were cured, while in two the remedy failed. In all the nine cases a slight diuretic effect was noticable. It is advisable to continue the use of the decoction for some time after the disappearance of the symptoms, in order to prevent relapses.

SURGERY.

CONSERVATIVE SURGERY FOR NASAL OBSTRUCTIONS AND DEFORMITIES.

In a demonstration in the nose and throat clinic (*Post-Graduate*, New York), Dr. Clarence C. Rice emphasizes the following points in relation to conservative surgery for nasal obstructions and deformities:

1. The only way to become skilful with instruments of examination and expert in diagnosis is to personally examine the upper respiratory tract of as many patients as possible.

2. Cases for operation on the nose should be selected only after careful deliberation, and the relation in size between the obstruction and the total capacity of the nostril should be considered. When in doubt about the necessity for operation, try for a time treatment by topical application.

3. There are many cases of so-called "hypertrophic rhinitis" where the apparent hypertrophies are nothing more than erectile tissue distended by blood or serum, and many of these do not require the application of any destructive agent. The effect of a weak solution of cocaine upon these will aid in the diagnosis.

4. Remember that we do not find advanced hypertrophic changes in young people. The soft tissues are nearly normal, so it is not wise to injure the physiological tissue by operative procedure.

5. Deformities of the nasal septum are usually the first pathological condition to appear, and are the cause of the later changes in the soft structure of the nose. The removal of this septal lesion should first claim the attention of the operator.

6. Do not produce by operative measures large ulcerations on the septum, if they can be avoided, as there may be present in the case some constitutional vice, and therefore the ulcerations will be healed with difficulty. Nothing is more efficacious in their treatment than the use of antiseptic washes and covering.

7. A "traumatic" atrophic rhinitis can be produced by destroying too much of the soft tissue of the nose.

8. When hypertrophic enlargements are present on both the anterior and posterior ends of the turbinated bones, reduce the anterior bones first, and the posterior ones will usually disappear without cautery application. The treatment of these by sedative and protective oily sprays may accomplish so much that the application of acids or cautery will not be required.

9. Use the galvano-cautery by inserting the pointed wire into the turbinated hypertrophy rather than by burning the mucous surface with the flat electrode.

10. Too much care cannot be exercised in the use of antiseptic solutions, both in preparing the nose and instruments for the operation, and also during and after the operation, until all ulceration is healed. Without the use of antiseptics the patient will surely suffer from sepsis.

THE OPERATIVE TREATMENT OF INTUSSUSCEPTION.

Hutchinson (*Arch. of Surgery*) says that the rule of practice in the early stages of intussusception ought to be invariably to try insufflation and injection, and it is only when they have failed that laparotomy ought to be thought of; they are not without risk, and must be tried with judgment and caution. There is no reason for preferring insufflation to the injection of water; for the latter he prefers hydrostatic pressure to the use of a syringe. In infants under two years of age laparotomy is so uniformly fatal that it should not be resorted to. Above that age, if injection has failed, a prompt resort to laparotomy should be recommended. It is desirable that this should be done early before the serous surfaces have become adherent. In the operation the chief difficulty is in releasing the incarcerated part. This is best done by pressure from below, not by traction from above. The older the patient the slower will be the progress of symptoms, and the longer the period during which it is possible to effect relief by operation. In adults a successful operation is possible even after a very long interval.—*British Medical Journal.*

MEDICINE.

PYORRHEA ALVEOLARIS.

M. W. Swartz (*Dental Review*) says: Pyorrhœa alveolaris, or Rigg's Disease, is first indicated by an uneasy sensation; then inflammation of the margins of the gums; looseness of the gums about the teeth, which form pockets; necrosis of edges of alveolar processes; a tendency to hæmorrhage, inflammation extending deeper into the gums; small sulci filled with pus; looseness of the teeth and change of position of the same; disagreeable taste; peculiar fetor of the breath; dark livid color of gums, with thick margins, and often extremely sensitive to the touch; in some cases the gums are denuded of their epithelium, with a polished appearance, in others with a pimpled surface; the teeth, at length, held in their cavities by a tough ligamentous attachment, due to the change occurring in the peridental membrane. A simple form of this disease may manifest itself at the gum margin, indicating its presence by a congested appearance, beneath which may be found a granule of calcified material. While in many cases there is a general congestion of the affected gum, and a proneness to hæmorrhage; in other cases the gum may present an anæmic appearance—pale and bloodless. This disease may also be associated with syphilis, mercurial salivation and scurvy. The deposit of salivary calculus and calcified substance is supposed by some to be secondary to this disease, as a deep red and denuded gum about the necks of the teeth may be present without any deposit. Yet in the vast majority of cases, this diseased condition is traceable either directly or indirectly to calcic formations about the neck and roots of the teeth.

First of all in any given case, completely remove all deposits from the teeth. Have no fears as regards the hæmorrhage of the gum during this operation or any part of this treatment of these cases. In practice I have found that free hæmorrhage in advanced cases seems to prove a benefit rather than a detriment. Also that when the gums become more or less lacerated during the removal of the deposit from the roots, the condition seems rather to promote a healthy condition than otherwise. However, considerable care should be exercised during this operation, for upon the extent to which the gums will be restored to their natural height and position about the root of the tooth, depends the condition of the remaining portion of the peridental membrane. And in fact it is quite as necessary to preserve the peridental membrane for this purpose, as it is to preserve the periosteum while operating upon diseased bone.

For an injection into the pockets after the removal of the deposit, I am partial to the use of peroxide of hydrogen. When it cannot be obtained fresh, I use a solution of carbolic acid, from two and one-half to ten per cent, or any of the other good antiseptics or disinfectants. For the purpose of injecting I employ a Dunn's syringe where the pockets are not very deep. When the pockets are deep, I employ the ordinary metallic syringe. I usually prefer it as one can then apply force enough to thoroughly wash out all foreign matter from the pockets.

After thoroughly injecting the pockets, absorb with absorbent cotton all moisture about the tooth to be further operated upon. And then by the use of a piece of soft pine wood cut in form of a tooth-pick, force into the pocket, its full distance, finely pulverized fresh cupric sulphate. For this purpose I employ nothing else. This operation will likely cause considerable pain, but never mind that. Heroic treatment is demanded. And if this operation is thoroughly performed at first treatment, in many cases nothing further need be done than the injection of the antiseptic and disinfectant. I am not in favor of too frequent treatment of these cases. And unless the case in hand is far advanced, I advocate the lapse of five or six days between treatment. Of course in the meantime I have the patient use some good antiseptic and disinfectant wash, alternately with a wash that tends to toughen and harden the gums. And in many of the milder forms of this disease after the removal of the deposit, I confine myself strictly to the employment of washes, and the results attained in almost every instance are very gratifying.

The washes I direct the patient to use are antiseptic and astringent in character.

VARIETIES OF VERTIGO.

Dr. Charles K. Mills (*Philadelphia Polyclinic*) says: No classification can be made to include every form of vertigo not

directly the result of labyrinthine disease, but the most important varieties are:

1. Vertigo dependent upon intracranial disease, chiefly tumor and pachymeningitis, but not including under this general head the disturbances of equilibrium arising from disease of the cerebellum or corpora quadrigemina. The three most frequent general symptoms of intracranial tumor are headache, nausea or vomiting, and vertigo; and these are commonly dependent upon the same mechanism. Most cases of brain tumor originate in the membranes of this viscus; the trigeminal nerve has a wide distribution in the dura, and intense localized irritation of its branches gives rise directly to pain and indirectly to nausea vomiting and vertigo. The deep nucleus of this nerve is closely related in position to the nuclei both of the pneumogastric and the auditory nerves, and the reflection or irradiation of powerful impressions from the former to the latter will cause vomiting and vertigo.

2. Ocular vertigo, which may spring from several conditions, but is most commonly due to serious disorders of refraction, to paresis or spasm of the ocular muscles, or to excessive retinal irritation. In any case the cause of which is obscure, the eye should be carefully considered and its defects corrected. Partial tenotomies and exact corrections or re-corrections with glasses have been found efficient, particularly in some of the milder but none the less annoying vertigoes.

3. Vertigo due to disease of blood-vessels, as anterior-sclerosis, from alcohol, syphilis, gout, old age, etc. The diagnosis of these cases is to be made by excluding carefully ear, brain, eye, severe local disease anywhere, toxæmias, etc., but chiefly by a careful examination for arterial or arterio-capillary fibrosis and the accompanying conditions of the heart, kidneys, liver and other organs. Reedy, resisting arteries, excessive arcus senilis, changes in the pulse rate, reduplicated or clanging cardiac sounds, and other well-known phenomena, will be present.

4. Vertigo which has its source in the state of the blood, under which general head are included those forms of the affection arising from anæmia or hyperæmia, lithæmia, and a large variety of toxæmias; and from the direct action of drugs and poisons.

5. Vertigo dependent upon intense irritation reflected to the labyrinth or brain from more or less distant regions of the body—commonly classed as nasal, pharyngeal, laryngeal, gastric, intestinal, hepatic, uterine, ovarian, etc. The reflex origin of these vertigoes is often doubtful; they are more probably due to a toxic state of the blood, which is produced in various ways. —*American Lancet.*

A NEW TREATMENT FOR PHTHISIS.

De Renzi (*Riv. Clin. e. Terap.*, No. 6, 1892) publishes a new treatment for phthisis, consisting in the use of iodine internally in the following form:

℞

Aq. dest.,	1000 grs.
Iodine,	1 gr.
Pot. iod.,	3 grs.
Sodium chlor.,	6 grs.

This was first injected into the ear vein of healthy and tuberculous rabbits, and into the subcutaneous tissue of dogs, rabbits and guinea-pigs. Complete tolerance being established, he tried the remedy on phthisical patients. Hypodermatic injections were first given, and as much as 100 grains were given; these were not, however, well borne, so the drug was then given by the mouth, using from 500 to 550 grains. Nineteen patients, nearly all with advanced phthisis, were thus treated. In all, the treatment produced increased appetite and increased flow of urine. Symptoms of iodism arose in a few instances, but disappeared on leaving off the treatment. The author is of opinion that the results of this treatment will compare favorably with those of any other at present tried; the body-weight increases, the number of bacilli diminishes in the sputum, and the temperature is reduced to normal—*Med. Age.*

HAY ASTHMA.

Dr. Edward S. Blair has treated a girl of ten years who for one-half of her life had been subject to annual attacks of this disease. Under the use of potassium iodide and grindela robusta there were slight catarrhal symptoms, but on lying down marked wheezing and dyspnœa. These symptoms were checked entirely by the fluid extract and euphoribia pilulifera [dose not stated], and the relief of these symptoms were followed by a marked increase in flesh and strength.—*Canadian Prac.*

GONORRHŒAL RHEUMATISM.

Dr. Brodhurst advises, as treatment for gonorrhœal rheumatism, that the affected joints be wrapped in lint covered with mercurial ointment, that they should be bandaged as firmly as can be borne, and that the patient should be brought rapidly under the influence of mercury, preferably by inunction. With such treatment, pain and swelling quickly disappear and the the joints resume their normal condition. At this stage passive motion should be instituted to ascertain if the motion of the affected joint is free, for lymph will have been deposited on the synovial-membranes through which adhesions form. These bands soon become firm and resist any attempt the patient can make to move the joint.

This treatment, according to the author, never fails if resorted to at the onset of the inflammatory stage. The knee, the hip, the elbow, and the shoulder are most frequently affected by this form of inflammation. Ankylosis may result—not in one joint only, but in every articulation of the body. When, after inflammation has ceased and passive motion has not been employed, adhesions remain and become firm, force is needed to restore mobility. This should always be used in the direction of flexion, since when thus employed no injury can accrue to any structure. Under some circumstances division of the flexor muscles is necessary. —*Therapeutic Gazette.*

METHYL VIOLET IN DIPHTHERIA.

Jaenicke (*Therapeutische Monatshefte,*) reports a number of experiments upon cultures of Lœffler's bacillus with methyl violet, and a few cases of pharyngeal diphtheria, in which he has used local applications of the substance. The number of his cases has been too small from which to draw conclusions, but in one or two days he noticed a fall of temperature, with coincident return of strength and appetite. He directs that a probe be covered with cotton and moisture in a saturated watery solution of methyl violet, and applied with considerable pressure to the membrane until it is colored a deep blue. In from two to five hours, when the color has disappeared from the membrane, a second application must be made. In cases where there is septic intoxication necessarily the local use of the methyl will not save the patient, but by its energetic use on new membrane he thinks it will prevent its further development. He has never noticed any bad results, either local or general. He concludes his article as follows: "Methyl violet recommends itself as a curative medicine for diphtheria.

"(1) Because it has an especially antiseptic action on Lœffler's bacillus. Its power of preventing the growth of the bacillus being greater than its power of killing the bacillus, the application of the substance should be repeated as soon as the diphtheritic membrane loses its blue color.

"(2) Because it remains in the pseudo-membrane as well as in the mucous membrane of the mouth for an unusual length of time, and its antiseptic power is thereby increased.

"(3) Because it is relatively less poisonous than other materials heretofore used." —*Univ. Med. Mag.*, Sept., 1892.

SILVER NITRATE IN DIPHTHERIA.

Dr. Piliére, of Paris, has since two years been treating diphtheria by means of swabbing the throat morning and evening with a cotton tampon saturated with a 1:30 solution of silver nitrate. He rubs the affected parts pretty briskly, so as to detach the false membranes; then the throat is sprayed with a 1:300 solution of corrosive sublimate, in children above two years of age, and with a 1:1000 solution in younger children—the spraying being repeated every two hours during the day and every three hours of the night. It is stated that no untoward effect is produced by this treatment, and that the diarrhœa which might occasionally occur will disappear of itself.—*Ex.*

INFECTIOUS ERYTHEMA IN DIPHTHERIA.

Mussey's *These de Paris,* 1892, treats of this subject. There are several kinds of erythema more or less constantly present in diphtheria—the polymorphous, the rubeolic, the scarlatinoid, and the desquamative scarlatiniform. Often these are transitory. Some are difficult to recognize, as purpuric erythema. Such eruptions are of graver import in regard to prognosis when occurring late in the disease.—*Ex.*

OBSTETRICS.

THE CORROSIVE SUBLIMATE DOUCHE.

A French physician, in a recent article on the use of the corrosive-sublimate douche in lying-in women, cites thirty cases of death due to poisoning caused by the drug employed in this way. In the fatal cases, the strength of the solution was 1 to 1,000, or over, in ten instances; 1 to 1,500 in two; and 1 to 2,000 in the remainder. The absorption of the poison, the writer states, probably took place in the uterus at the site of the placenta. The symptoms observed were profuse diarrhœa with tympanites, vomiting, stomatitis, renal complications, pulmonary congestion, bronchitis, broncho-pneumonia; later on, circulatory disturbances, torpor, prostration, and collapse. The skin is either dry, or covered with cold and viseous perspiration; there is itching, which often precedes death; and, especially, a very peculiar and often generalized erythematous eruption. Lenticular spots also appear, which grow larger and of a deeper color at their periphery; they join together and form large blotches on the face, extremities, and trunk. The significance of this erythema is serious. It was often observed, shortly before death in cases where a cure had been looked for.

The writer concludes his article by stating that corrosive-sublimate must be used with "science and prudence in confinements, and that it is dangerous in inexperienced hands."

At a recent meeting of the Obstetrical Section of the New York Academy of Medicine, Dr. Von Ramdohr called attention to the danger of corrosive-sublimate douche, even in weak solutions. He said he did not see why physicians persisted in using it until a fatal case of poisoning came under their personal observation.—*Doctor's Weekly.*

RESULTS OF GONORRHŒAL INFECTION IN WOMEN.

Von Rosthorn, in the *Präger Medicin. Wochenschrift,* 1892, states that the prognosis of gonorrhœal infection is favorable as long as the poisonous process does not invade the cervix. When this happens, rapid extension of the inflammation results, an "ascending gonorrhœa" causing marked changes in the genital tract and surrounding tissues, with special preference for the endometrium and tubes. The dependent portion of the pelvic peritoneum also becomes involved. There may be latent gonorrhœa that is without acute stage, and insidious in its development. Later, this may become an ascending gonorrhœa with its adverse consequences. It is possible to cure the infectious disease itself, but the uterine catarrh and adhesions remain, starting up morbid processes at each menstrual epoch. In regard to accidents connected with the puerperal state, the author does not consider gonorrhœa as important a factor as Saegener does. In the acute stage applications of tannin and iodoform to the vaginal mucous membrane are recommended, and injections of bichloride of mercury, one part to one thousand. Cauterizations of the cervix with fuming nitric acid can also be employed, but intra-uterine medication is to be avoided. In the later stage of infiltrations, adhesions, and cicatrices that cause pain, according to the Thuer-Brandt method is of great value, together with the intra-uterine galvano-caustic. Observations based upon one hundred cases lead to the belief that removal of the tubes will always result in almost permanent freedom from pain. These cases have to be watched constantly after the operation, to insure the prophylaxis of ascending gonorrhœa.—*N. Y. Med. Record.*

NARCOSIS IN OBSTETRICS.

Dührssen (*Berlin. klin. Wochenschr.*) considers that an anæsthetic is of great diagnostic as well as therapeutic value. The patient (often much excited) can be kept quiet by a few drops of chloroform whilst certain important factors in labor are being ascertained, such as frequency of the fœtal heart sounds. Primiparæ are often very troublesome to explore, and it is then only by the aid of anæsthetics that the obstetrician can make sure whether the head has already entered the pelvic cavity. Narcosis is valuable for the timely diagnosis of occipito-posterior and transverse presentations. In explorations where the entire hand must be introduced into the uterus, anæsthetics are, of course, indispensable. For therapeutic purposes narcosis is needed for turning, especially combined external and internal version, for

detaching adherent placenta, manual removal of ovum and membranes in abortion, reposition of impacted tumors during birth, the management of prolapsed foot in breech presentation, and turning in incomplete dilatation of the os in multiparæ. In irregular contractions of the uterus chloroform often hastens labor. Sepsis is, in Dührssen's opinion, a contraindication for anæsthetics, and deep or long-maintained narcosis is dangerous in cases of eclampsia. It should only be induced, in such cases, to facilitate rapid delivery by operation. Tetanus uteri is also a contraindication. In acute anæmia a very little chlorolorm will take effect. When chloroform is given, Dührssen advises the obstetrician to get the patient well under, and then to leave the mask in the charge of the midwife, who must from time to time pour a few drops into it.—*British Medical Journal.*

GYNECOLOGY.

PERITONEAL ADHESIONS AFTER OVARIOTOMY.

Ovariotomy appears to be a somewhat more serious operation than we have of late thought it to be; for we are now learning something of the remote dangers which result from the adhesions of peritoneum and bowels formed during the convalescence from the ovariotomy. In the *Lancet*, September 10, Dr. Phillips of London, relates several fatal cases (one his own) in which such adhesions (found post-mortem) had caused death. We extract the report of one case, with Dr. Phillips' remarks on it:

Case 3 (Shively).—The patient was forty-five years of age; ovariotomy was performed four or five years before, since which time she has been constipated and has had periodic attacks of colic, which usually gave way to subcutaneous injections of morphia. She took a dose of cathartic pills one morning shortly before her illness began, and a good action had taken place; colicky pains, however, unsued in the evening. The pain increased and sickness began, but no tympanites appeared; long tube enemata were given repeatedly, but no further action took place. The vomiting and pain increased, and the patient died after several days' illness.

The post-mortem examination revealed a complete key to the illness. "There were extensive adhesions of the intestines to the sides and posterior wall of the abdomen, binding them firmly down." This was doubtless the reason for the non-appearance of tympanties. A portion of ileum eighteen inches above the cæcum was adherent to and incorporated with the cicatrix of the wound of the previous ovariotomy. "Around the short portion, between this and the cæcum, a loop of small intestine was twice twisted, forming a kind of knot," and a complete occlusion was thus produced. The direct cause was doubtless the cathartic given on the morning of the commencement of the illness, possibly assisted by some favorable position assumed by the body.

We have therefore three distinct varieties of causation of intestinal obstruction after ovariotomy: (1) When the adhesion arises from the stump; (2) from the cicatrix of the abdominal wound; (3) from intestine to intestine. The small intestine, in consequence of its greater mobility, is liable to form adhesions with any abraded surface; hence we find them more common in connection with the small than the large intestine. Martin, of Berlin, has proved, as the result of observations on second operations on the same patient, the presence of slight non-septic peritonitis as the immediate effect of every ovariotomy. The colicky pains which patients often suffer from after ovariotomy, and complicated with constipation, are due to small peritonitic adhesions, the result of this localized non-febrile peritonitis Hunter has devoted a paper to this subject and it is well worthy of perusal. If the prevention of formation of adhesions could be arrived at for forty-eight hours after operation, our position would be a more favorable one. In an interesting paper by Dr. R. T. Morris on this subject he declares that he has completely demonstrated the fact that an application of a film of aristol to the stump prevents secondary peritoneal adhesions; he experiments on rabbits and relates one case of abdominal section in the human object. The above facts seem to point strongly to the desirability of our knowing the subsequent histories of those patients whose cases fill the long lists of ovariotomies published from time to time and classed as complete successes. —*Maryland Medical Journal*, Oct. 15, 1892.

HYGIENE.

THE DIETETIC TREATMENT OF ULCER OF THE STOMACH.

Dr. F. Roux states that the treatment of this disease must not be based upon the principle of reducing the work done by the stomach to a minimum. The diet must consist of substances which are digested in the intestines, such as milk, eggs, farinaceous food, fruit, and green vegetables. Farinaceous foods play an important part in the treatment of gastric disease; together with eggs they should constitute the chief diet, but in order that they may not irritate the gastric mucous membrane they should be administered in a soluble form. Of potatoes, beans, and lentils, the meal of the latter is probably the best, as it contains a large amount of nitrogen and a quantity of iron equal to that contained in meat. Light puddings are nutritious, especially when made with eggs. Green vegetables are useful; carrots and turnips should be mashed; green peas and salads may be eaten; cabbage should be prohibited; fruits should be cooked, as they ase not readily digested in the raw state. The single exception to this are grapes, which can be given at any time and in any quantity, especially if constipation is present. They are best taken in the morning and middle of the day.—*Journal d' Hygiène.*

THE CARE OF THE HAIR.

To much emphasis cannot be laid on the fact that the hair should be cared for intelligently, appropriately and regularly. It should be cleaned in tepid water once every week, and once a month—presuming there be no disease like abundant dandruff or any other scalp trouble—with a very mild solution of some simple alkaline substance like borax or bicarbonate of soda.

It is always better to wash the scalp and hair before retiring, as the opportunity for drying it is better, especially if the hair is thick or heavy, and there is less likelihood of taking cold. Many of the finest suits of hair we have ever seen have been preserved and kept beautiful by the simple use of tepid or cool (not icy) water, the year round at morning toilet. As with everything else so with the hair, good judgment must be the guide. The fine comb, as an article of use for the hair, should never be thought of; the centre of a hot fire is the place for a fine comb, A good brush is the great tonic for the hair.

DRESSING THE HAIR.

Some writers utterly prohibit the use of oil or grease on the hair; others unduly magnify the advantages of its constant applications; but between abstinence and unlimited use is the true plan. Some hair is harsh and dry, do for it what you will; such hair requires the occasional application of oil; other hair is alawys oily and "just right; " for the latter very little "dressing is required.

PRESERVING THE HAIR.

To keep a "heavy head of hair " is the desire and delight of every one. The law of heredity excepted, there is no reason or cause why so many should be bald or have thin or "patchy " hair. Carefully attending to the hair, having it trimmed at regular intervals, keeping the scalp clean, never allowing a barber to use other than your own brush and coinb in arranging your hair, avoiding the constant wearing of a hat—these are all contributing influences towards the preservation of the hair "e'en down to old age" and the grave.

WE WANT EVERY PHYSICIAN TO KNOW THAT

PHILLIPS' COD LIVER OIL

EMULSION,

Represents, in all essential features, the highest degree of perfection in the Emulsionizing of Cod Liver Oil.

We believe it to be the only Emulsion not advertised to the public.

PHOSPHO-MURIATE OF QUININE

COMPOUND.

A RELIABLE ALTERATO-CONSTRUCTIVE

Particularly applicable to conditions of **MAL-NUTRITION.**
A reliable TONIC in CONVALESCENCE from the exanthemata and of obvious indication in those cases whose deficiency of the Phosphates results in GLANDULAR ENLARGEMENTS, SCROFULOSIS, IMPERFECT BONE FORMATION, or IMPAIRMENT OF THE CENTRAL NERVOUS SYSTEM. An easily appropriated and stable combination of the Soluble WHEAT PHOSPHATES with MURIATE of QUININE, IRON and STRYCHNIA.
Of greater strength than the various Hypophosphite compounds.

In Dispensing and Trade Containers.

DIGESTIBLE COCOA.
WHEAT PHOSPHATES.
MILK OF MAGNESIA.

INFLAMMATION ABOUT THE CAPUT COLI.*

By G. FRANK LYDSTON, M. D.,
CHICAGO.

PROFESSOR OF THE SURGICAL DISEASES OF THE GENITO-URINARY ORGANS, AND VENEREAL DISEASES, IN THE CHICAGO COLLEGE OF PHYSICIANS AND SURGEONS.

It is with some hesitation that I have selected a title of so general a character for the paper which I have the honor of presenting to this Society. It has come to pass in the case of inflammation in the vicinity of the colon that most of our writers are attributing all of the inflammatory affections in this region to pathological conditions of the appendix. The reason for this is not far to seek. Most of the recent work that has been done upon this subject has been done by operating surgeons, especially those of abdominal tendencies. These operators are necessarily brought in contact with the more serious cases of inflammation about the caput coli. *i. e.*, those in which pus has either formed or will inevitably do so within a short time, and it must be confessed that in these cases the appendix is most often at fault. The general practitioner comes in contact with both classes of cases, those in which the operation is required, and those in which recovery occurs without surgical intervention. The surgeon—who is most frequently called in only when an operation is inevitable—necessarily looks upon the subject with an operative bias, and is apt to say without qualification, that all cases of inflammation about the caput coli require operation. If, on the other hand, the general practitioner has a run of cases in which recoveries without operation preponderate, which is very often the case, he is apt to assume an ultra-conservative position. I have heard surgeons support the operative treatment in most radical terms of these cases without the least qualification or the slightest attempt at differentiation of cases and conditions. On the other hand, I have heard practitioners of experience assert that operation is never indicated, and that conservative treatment should be adopted as a matter of routine. For example, I heard a practitioner of many years' experience, state at an important society meeting, that the free administration of opium and the faithful application of hot poultices was the only treatment which was warrantable in cases of this kind. In support of this position, he stated that his father before him had treated such cases in a similar manner and with success, and that he hoped that this son, who was to follow him in his practice, would also treat them in that way. It was rather painful to note this addition to the list of hereditary fatalities, and it would, I presume, have been a hopeless task to convince this old gentleman that certain cases of peritonitis of a fatal character, which had occurred in his practice, were due to undiscovered or neglected perityphlitic abscesses.

With regard to the statistics compiled with a view of determining the relative value of conservative and operative measures, it is probable that we will always experience extreme difficulty in forming a positive opinion. The surgeon reports a long list of cases, showing the brilliant successes attendant upon operative measures, without the least attempt at

*Read before the Miss. Valley Medical Association, October, 1892.

discrimination as regards the relative gravity of his cases. Not all surgeons are open to criticism in this respect, it is true, but unfortunately we are compelled to rely for our statistics, not upon the cases of a few experts, but upon the cases of a large number of practitioners, many of whom may be classed as the average surgeon, whose opportunities for the post-mortem verification of diagnosis and for the comparison of a large number of cases are rather limited. Some reports are based mainly on cases of operation, the gravity of which is no greater—as far as the operation, *per se* is concerned—than that of opening an ordinary abscess. Other reports are based upon cases requiring active interference with the caput coli and resection of the appendix. In other instances, the surgeon is not appealed to until rupture and infection of the general peritoneal cavity has occurred. Necessarily there is in such cases a very meagre prospect of cure by operation, yet such cases are accredited—and I think unfairly—to the sum-total of operations for perityphlitic abscess, or appendicitis, if you please. I think that the necessity for a careful differentiation of cases in order to enable us to come to a rational conclusion as to the comparative value of radical or conservative measures is at once apparent. I believe, moreover, that the conservative practitioner and the abdominal surgeon should not work on parallel lines, as seems to be the tendency, but upon those which converge to logical conclusions of the advisability of occupying a middle ground in the controversy. The surgeon is a potential force for the accomplishment of greatly-needed work in cases of inflammation about the caput coli. He often, however, is more efficient for good when he brings the experience of the level-headed, conservative, general clinician to his assistance. A series of successful conservative cases under conservative measures by no means proves that a routine conservatism is best in such cases, neither does an occasional case dying without operation, when every expert surgeon knows that an operation may have saved life, prove that operation is indicated.

Nowhere has modern surgery been characterized by more signal triumphs than in the pathological study, diagnosis and treatment of inflammation about the head of the colon. This great advance in our knowledge and surgical resources is to be attributed to the arduous labors of American physicians and surgeons,among whom Sands, Weir, Morton, Hoffman, Fitz, Pepper, McBurney, Dennis, and Stimson are especially prominent. The papers of Dr. McMurtry,of Louisville,and Drs. Murphy and Lee, of Chicago, have been important contributions to this subject,

It was long believed that inflammation of the cellular tissue about the colon was the main factor in perityphlitic inflammation. Modern pathologists and abdominal surgeons have disapproved this theory as far as its general applicability is concerned, and have attempted to show that a diseased appendix is the *fons origo et mali* in practically all of these cases, abjuring the cellular tissue altogether and seeming to believe that by some peculiar dispensation of Providence, cellular tissue in this location is protected from those causes of inflammation and suppuration which are potent elsewhere. This, it would appear, is an extreme view and one which bids fair to work sad havoc with the luckless appendix. It has even been facetiously suggested that the only salvation for the human race is a prophylactic excision of the appendix as soon after birth as practicable. Whether this would result some generations hence in an appendixless type or man is a question, but if rats may be bred without tails, I suppose such a result will not be too visionary for considera tion if the present furor of excitement over the appendix keeps up. Like Davy Crockett after the coon, when the enthusiastic surgeon starts after the appendix he is bound to get it. It remains to be seen what he will do when the appendix becomes obsolete. Much as we may deplore surgical radicalism, the female ovary has had much to be thankful for since the attention of the abdominal surgeon has been directed to the appendix.

Regarding the relation of the cellular tissue to abscesses about the colon, while it is undoubtedly true that in the majority of cases it bears the same relation to inflammation, and perhaps perforation, of the appendix that so-called pelvic cellulitis bears to pathological conditions affecting the uterine appendages, and is of a purely secondary nature, it should, I think, be assigned a little more important rôle than

most abdominal surgeons believe. It would certainly seem to be true that in many cases of perityphlitic inflammation, involvement of Velpeau's membrane—the extra-peritoneal cellular tissue—has much to do with the peculiarities of the resulting abscess. A point which seems to me of some importance and which was brought out in a very positive manner by my friend Dr. McMurtry, of Louisville, in a paper before the Southern Surgical and Gynecological Association in 1891, is the arbitrary assertion that the inflammatory process and resulting abscess in cases of inflammation about the caput coli are always intra-peritoneal. This assertion is based upon the recent anatomical dissections of Treves, Bull, and others, which seem to show that the appendix and cæcum are wholly within the peritoneal cavity. It has also been shown by such operators as McBurney and others, that the abscesses are usually intra-peritoneal. This assertion requires qualification, for general practitioners will very often allow a perityphlitic abscess to rupture spontaneously, either externally—which happy event occasionally occurs—into the cæcum, or, with an almost inevitably fatal result, into the peritoneal cavity, because of the horror which men of small experience in abdominal operations have of the peritoneum. In other cases the abscess will be allowed to burrow in various directions to appear at some point far distant from the original focus of suppuration. These disagreeable results are permitted in the face of the fact that a simple incision into what is practically an ordinary abscess would prevent them. A pointing perityphlitic abscess—intra-peritoneal though it may be—is practically extra-peritoneal because if the barrier of lymph, young connective tissue, and agglutinated intestine that shuts it off from the general peritoneal cavity. This point I believe to be of paramount importance. In some cases it would appear that the inflammation may agglutinate the peritoneum about the appendix, and form an abscess of small size which perforates through the retro-peritoneal cellular tissue. This appears to me to be the explanation of the tardiness with which some abscesses in this location come to the surface. Instead of the induration being at once manifest it may be some days or weeks before it can be detected with any degree of positiveness. The abscess meanwhile burrows along the planes of cellular tissue in the iliac fossa to the ileo-lumbar region and may appear at some distance from the head of the colon, or may gradually burrow outward toward the loin and downward and upward in the direction of the groin until at one or both points it becomes perceptible to the touch. In several cases in which I have operated, I have every reason to believe from the conditions present that the process was extra-peritoneal, and that the abscess had burrowed up in the direction of the kidney as well as downward into the iliac fossa. The point which I wish to emphasize is that even though these abscesses be considered *ab initio* intra-peritoneal, the operator must not lose sight of the fact that in some cases he can do what is practically an extra-peritoneal operation, for there is at least a barrier produced by adhesions which shut off the collection of pus from the general abdominal cavity.

In view of the prominence which inflammation, gangrene and perforation of the appendix has been accorded in the etiology of suppurative processes about the caput coli, it may seem rather bold to express a belief in the occurrence of such inflammatory troubles without such serious disease of the appendix. It must be admitted that such cases very often get along very well without operation, and perhaps do not even suppurate, but this should be accepted as at least a partial explanation of the arbitrary position of the surgeon. The cases in which serious disease of the appendix exists must come to suppuration and should, as a rule, be operated upon, while in many of those in which the appendix is not involved to a serious extent, conservative measures may succeed with the result that the surgeon has no opportunity of examining the case. I think that general practitioners of experience will be inclined to recognize cases of inflammation about the colon which do not begin in the appendix *per se*, but have for their starting-point inflammation in the colon proper. I can see no reason why this inflammation may not extend to the cellular tissue outside of the colon without there being necessarily any perforation or even any suppuration. This extension of inflammation, I believe, does occur and in all likelihood is the result of infection. A comparative study of the bacterium coli com-

mune and pyogenic microbes may in the future shed some light upon the subject. The close similarity or, as is claimed by some, identity of the two forms of microbe is suggestive to say the least. Whether inflammatory conditions in and about the appendix and colon may give rise to evolutionary changes in the bacterium coli commune by which it acquires properties of infection and pyogenesis, is at least an open question, and one upon which the bacteriologist is alone competent to pass an opinion.

The relation of foreign bodies to appendicitis and the pathological processes secondary thereto, might be considered to be quite definitely settled were it not for the fact that every now and then contributions to medical literature appear in which foreign bodies are assigned a very unimportant place in the etiology of the disease. Within a year I heard a prominent abdominal surgeon state, that in his opinion foreign bodies were very rarely the cause of perforation of the appendix with resulting abscess, he citing a number of cases in which he had evacuated large abscesses in this situation and had removed the appendix, and had not been able to detect a foreign body of any kind. I was not convinced on listening to this gentleman's description of the cases that they conclusively proved that foreign bodies were not present even in them. A foreign body of very small proportions is doubtless sufficient to cause appendicitis and it is conceivable that the finer fruit seeds and even foreign bodies of a large size might easily be overlooked in the cavity of the abscess or the pus which discharges therefrom. A foreign body is, as is well known, not necessarily of extraneous origin. It is probable that in some cases of appendicitis a catarrhal colitis is the point of departure for the pathological process. Obstinate constipation may lead to a catarrh of the colon, which process extends to the appendix with a resulting slight swelling of the appendico-cæcal opening. The resulting formation of a fæcal stone is so well known that I would not repeat it were it not necessary to a complete presentation of the subject. Mucus collects in the appendix, a small amount of fæcal matter gets into the tube during straining at stool, and fails to get out again, and forms in combination with the mucus a small fæcal stone. Sometimes this fæcal stone is formed in the cæcum and is forced into the appendix, although it is probably most often formed in the appendix proper. A practical point in this connection, to which I believe attention has not been called, or at least if so, it has not been brought to my attention, is that in certain cases of inactivity of the colon with resulting constipation and catarrhal colitis, abdominal massage, which is so frequently recommended and which is so often beneficial in constipation, is apt to be a source of danger. A small portion of fæcal matter may be forced through the partially stenosed appendico-cæcal opening, and once imprisoned in the appendix it will become as truly a foreign body as though it were of extraneous origin. The fæcal stone may set up a varying degree of inflammation of the appendix according to the degree of distension of the little tube. Frequently, as is well known, it perforates and produces inflammation and suppuration about the head of the colon. It is probable that in some cases the fæcal stone dissolves in the resulting pus formation, and this would seem to be the explanation of many of those cases in which perforative ulceration of the appendix is found and yet no foreign body is discernible in the pus sac. It is not impossible that in every case where perforation occurs there has been a foreign body of some kind. Many cases of appendicitis remain catarrhal, and may cause little or no disturbance of the patient's health. The frequency of this condition is well shown by Fitz in his analysis of 72 cases in which appendicitis was probably not suspected during life.

With regard to the dependence of appendicitis upon foreign bodies, a very interesting case was reported by my friend, Dr. C. A. L. Reed, of Cincinnati, in the Transactions of the Southern Surgical and Gynecological Association for 1890. He was called to see a fine, stalwart woman, who had been troubled with constipation for the relief of which she had taken a regular diet of compound cathartic pills. She had suffered for two weeks with inflammation about the caput coli, the diagnosis of which was indisputable. Laparotomy disclosed a very large pus cavity; this was opened and irrigated; the appendix had disappeared, and in the cavity of the abscess were found half a dozen of the compound cathartic pills. While I am speaking of the relation of foreign bodies

to appendicitis, some members of this society are doubtless recalling cases, either personal or reported in the journals, in which perforation, gangrene, and perhaps spontaneous amputation of the appendix has occurred, yet no foreign body has been discoverable. It might not be amiss in this connection to again suggest the readiness with which a foreign body may be overlooked and the possibility of a fæcal stone dissolving in the resulting pus. No one has yet made clear the reason for such an intense inflammation affecting a structure anatomically and functionally so unimportant as the appendix vermiformis. Leaving out of consideration some special type of infection or the impaction of foreign bodies, such pathological processes, to say the least, are difficult of explanation.

Causes:—The causes of inflammation in and about the head of the colon may be summed up as: (1) Fæcal impaction. (2) Fæcal stone. (3) Extension of catarrhal colitis with occlusion of the mouth of the appendix. (4) Foreign bodies of extraneous origin. (5) A possible primary infection of the appendix and the tissues about it by pus microbes. (6) Traumatism. The latter cause may be disputed, but I have observed one case in which it appeared to be the starting-point of the disease. It is not difficult to appreciate the possible importance of traumatism. A blow upon the abdomen over the distended colon might, it seems to me, give rise to a bruising of the colon with resulting inflammation, which may extend to the appendix and the retro-peritoneal cellular tissue, or may cause extrusion of fæcal matter into the appendix with resulting fæcal stone and its sequelæ. The relation of fæcal impaction in the colon to perityphlitic abscess is possibly more important than is generally believed. In two cases of my own in which an abscess resulted, and in which I performed an operation, there had been no constipation before or during the patient's illness, yet some days after the operation a large fæcal mass descended into the rectum, and I was compelled to remove it in each instance by mechanical means. As the patient had been having a stool daily under the use of salines, the most likely point at which this fæcal mass could have formed was the caput coli. I can appreciate the possible objection that the impaction was the result rather than the cause of the inflammation. It is a noteworthy point that perforation of the appendix results so often in a limited inflammation, while perforation of the stomach is immediately and almost inevitably followed by a fulminant peritonitis. Mynter explains this, by the more active peristalsis of the stomach and small intestine, which results in a more speedy and liberal distribution of the infective matter over the peritoneum. The comparatively small calibre of the appendix and the slight *vis-a-tergo* imparted by the small quantity of fæcal matter in its lumen, constitute a more logical explanation. Both factors are probably operative.

Experience at the bedside and autopsy table, has permitted of a tolerably definite classification of appendical inflammations. One of the best classification is that of With, of Copenhagen, which is as follows: 1. Peritonitis appendicularis adhæsiva; 2. Peritonitis appendicularis localis; 3. Peritonitis appendicularis universalis.

Diagnosis.—The diagnosis of perityphlitic abscess is confessedly not always easy, as it is shown in one of my own cases in which I stood ready to operate, the symptoms pointing clearly to the existence of pus, and the fullness of the ileo-cæcal region and tenderness at that point seeming to warrant an operation. In this case the patient recovered after the passage of a large amount of fæces. Fitz reports a case of circumscribed peritonitis in the right iliac region diagnosed as appendicitis, which was afterward proven to be on autopsy abscess of the liver due to catarrhal colitis. In a second case, diagnosed as appendicitis, the post-mortem disclosed a suppurating sub-peritoneal gland, due to gonorrhœal infection. In a third case pyosalpinx was mistaken for appendicitis. In a case of my own, appendicitis existed with a small abscess, but all of the symptoms which existed prior to the operation have persisted for a long time, and were due in all probability to spinal irritation. This case was not operated on by me, but was under my care some months after the operation, and finally drifted into Dr. Senn's hands, and was, I understand, cured by spinal counter-irritation. A valuable point in diagnosis in obscure cases is the fact, that when an abscess, forming about the caput coli, tends to burrow upward toward the kidney, there will be

marked irritation of the psoas muscle, marked flexion of the thigh, crural neuralgia, and great pain on attempts at straightening the limb. Dr. McMurtry, in his excellent paper already alluded to gives this as one of the typical signs of appendicitis, but I have not observed it as a prominent symptom excepting in cases in which the abscess had had a tendency to burrow in the direction indicated. In these cases the diagnosis was not positively made early in the case, and this symptom came on only after the abscess had in all probability opened into the retro-cæcal cellular tissue and developed a secondary pus sac in that situation.

One of the things that the general practitioner is likely to do when he discovers an induration characteristic of perityphlitic inflammation, is to plunge the needle of an aspirator or hypodermic syringe into the mass. I never could understand why the practitioner should do this, for as a rule he does not intend to operate when he finds pus, and the inspection of a few drops of stinking pus is not likely to give very much assistance in a diagnosis which is already clear. If the pus has not formed, the induration not only does not require aspiration, but there is danger of infecting the peritoneum by the needle. If pus has formed, aspiration does no good, and there is still greater danger of infection. Very often the aspirator is relied upon as the crucial test for the diagnosis and an operation is decided against because pus is not withdrawn by the needle. As a matter of fact, however, it is difficult to get at the pus with a needle excepting in those cases in which the abscess has fortunately come forward in the direction of the anterior abdominal wall. Even in these cases, if the anterior peritoneum is not agglutinated to the abscess sac, the introduction and withdrawal of the needle may be followed by infection of the general peritoneal cavity, septic peritonitis, and death. Aspiration then, may be set down as on the average dangerous and about as logical as the performance of the ostrich who seeks safety by sticking his head in the sand. If the practitioner is not secure in his diagnosis, and is not capable of doing abdominal work, he should not be deluded into a show of industry by the facility with which he can jab a needle into the induration in the iliac fossa. Are there any circumstances under which aspiration might be advisable? When the pus has come well forward and the abdominal tissues are involved in the agglutinating process of the abscess walls, and it is necessary to convince the patient or the physician in charge of the necessity of an operation by an impression upon the ocular or olfactory apparatus of the doubting Thomas, aspiration may be prayerfully considered.

One of the most important points in connection with appendicitis is that many cases of so-called idiopathic peritonitis are dependent upon a fulminant attack of appendicitis which spreads so rapidly to the general peritoneum that acute peritonitis occurs and masks the primary trouble in the right iliac region. It is probable that in many children who are said to have idiopathic peritonitis there has really occurred primarily, inflammations about the appendix. In children, however, the inflammation may extend to the sensitive peritoneum so rapidly that a fulminant peritonitis results and destroys the little patient's life long before the period of pus formation, while in the adult suppuration and a distinct tumor will be observed. The more carefully these cases of peritonitis are studied, the narrower the range of idiopathic peritonitis becomes. Appendicitis and traumatism are often at the bottom of so-called idiopathic peritonitis. One of the cases which I shall shortly relate was probably an illustration of the rapidity with which the inflammatory process in the appendix will extend to the general peritoneum. Many times perhaps, general peritonitis has been preceded for some time by inflammation of the appendix of a low grade, the symptoms of which have not been sufficiently prominent to attract attention. Suddenly, however, gangrene or perforation occurs with resulting infection of the general peritoneum, and within a few hours the patient is in the agonies of what is labeled "Idiopathic Peritonitis."

Should the mortality rate reported from operations for perityphlitic abscess be an arbitrary guide in deciding the question of the advisability of an operation? It would seem not. Each case should be judged upon its own merits and an occasional error in judgment should not condemn conservatism on the one hand, or operation on the other. Operation for the results of appendicitis

necessarily varies in its gravity with the condition present. Thus it may be (1) surgically extra-peritoneal, albeit it may be anatomically intra-peritoneal. (2) Intra-peritoneal, the condition being nothing more nor less than a septic peritonitis, the operation perhaps being preformed when the patient is in a desperately bad condition. (3) The appendix may require resection. (4) The operation may be no more formidable than the evacuation of an ordinary abscess, the latter being the kind of cases in which some operators have achieved their greatest glory. (5)The appendix may be removed in the interval between the attacks of recurrent appendicitis. Obviously the mortality rate will vary greatly in these conditions. The mortality of appendicitis, as recorded up to date, is extremely severe. Fitz, who has reported more cases than any other writer, states that 74 per cent. of cases have recovered and 26 per cent. have died, about one half of these cases being treated medically and the other half surgically. As McMurtry remarks, "this indicated that those treated surgically were operated upon late in the disease," which may have meant that the patients were practically moribund. The late operation has had the enormous mortality of 50 per cent.

It is not my intention to expatiate upon the treatment of inflammation about the caput coli. There are some points, however, that will bear mention. It is probable that the tendency in such cases is to overdose with opium, while perhaps the objections which apply to the use of opium in general peritonitis do not apply so pertinently to the localized inflammation under consideration, it should, at the same time, be used with extreme caution. Should pain be severe morphia hypodermically in moderate doses may be warrantable, but great care should be taken—especially in administration by the mouth—lest the digestive organs be disturbed and vomiting result, which might prove disastrous to a patient in this condition. As a rule, local applications will accomplish the desired analgesic effects. Piping hot poultices, sprinkled liberally with laudanum, are always in order. An application which has in my hands proved a desirable substitute for the internal administration of opium in abdominal affections of a painful character, is an ointment with lanoline for a base, to which is added menthol, extract of aconite, belladonna, and extract of opium in considerable strength. Salines in full and frequent doses constitute, it seems to me, the only rational measure of internal medication.

Selection of Cases for Operation.—Wylie has stated that, "should the symptoms of a local peritonitis in the region of the cæcum not begin to improve by the fourth or fifth day from saline treatment and local applications over the seat of the inflammation, an incision should be made down through the muscles and the peritoneum dissected up until a place is found where the abscess is attacked, when it should be opened. While the operation would be less difficult if delayed, the danger of the abscess rupturing and producing acute septic peritonitis must be borne in mind, hence an increased difficulty in doing operation is more than compensated for in the risk saved the patient." McMurtry says: "Operation involves less danger than delay, and should be resorted to in all cases in which the high grade of inflammation is persistent." The essential of the operative technique according to this authority are "brief anæsthesia, quick and thorough work, removal of the appendix, irrigation and drainage." From my limited experience of observation of these cases, I believe that the safest guides are the pulse, temperature, degree of sensitiveness of the region involved, and the rapidity with which the induration occurs. Cases of the fulminant type, such as occurred in one of Chicago's well-known citizens, which was operated upon by Dr. McBurney a short time ago, demand immediate operation, and should be regarded in the light of a septic peritonitis from a surgical standpoint whether general involvement of the peritoneum has begun or not. Many cases will occur in which conservative measures are indicated, but in every such instance the attending physician should call a capable surgeon into the case in order that the operation, if indicated at all, may be done sufficiently early. In cases which are seen after fluctuation has occured, or when there is no fluctuation but agglutination of the mass to the structures of the abdominal wall, or in any case in which we are reasonably certain that pus has already formed, operation should be performed at once if the purulent collec-

tion is at all accessible. The pus should never be allowed to select its own exit, for while it may burrow in a favorable direction and open spontaneously at a favorable point, we have no assurance that it will do so, and our duty is to make a favorable point for it. A conservatism which permits an abscess in any of the great cavities of the body to knock at all doors in the neighborhood in the attempt to find the point of least resistance with the results oftentimes of escaping at a door which opens into some vital structures or organs of the body, is not the kind of conservatism that is must conducive to our patient's welfare.

As for the appendix, the statement made in Dr. McMurtry's paper, that it should always be removed is probably too arbitrary. Many cases recover after the evacuation of the abscess without removal of the appendix and without subsequent recurrence of the inflammatory process. Cases recover spontaneously by discharge of the pus into the bowel or externally without recurrence of the disease. The question should be decided not in a routine manner, but according to the conditions which the affected part presents. The site of the incision in operations for the relief of appendicitis and its sequelæ has been the source of some discussion, some surgeons advocating a perpendicular incision, others one corresponding to the direction of Poupart's ligament, and still others a combination of both. It would seem that we have here another opportunity for the differentiation of cases. Where there is a palpable tumor its axis is very apt to be in the general direction of Poupart's ligament, and under such circumstances an incision as for the ligation of the external iliac is advisable. Under other circumstances it may be preferable to make a vertical incision over the caput coli or perhaps combine the two incisions, a proceeding which is very apt to be necessary in order to expose and remove the appendix.

In presenting this general survey of inflammations about the caput coli, there has been no attempt at completeness. If I shall have succeeded in stimulating a discussion on the more important practical points—which points have been aptly illustrated by cases in my own moderate experience—I shall have accomplished my object.

Clinical Lectures.

ABDOMINAL GROWTHS.*

By E. E. MONTGOMERY, M. D.,

PROFESSOR OF GYNECOLOGY, JEFFERSON MEDICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL; GYNECOLOGIST TO ST. JOSEPH'S HOSPITAL.

Ladies and Gentlemen: The Patient I bring before you is a woman, twenty-one years of age, servant, unmarried, whose father died of acute alcoholism, and mother and four aunts of phthisis. Her childhood was uneventful; puberty occurred at twelve and menstruation has always been prolonged, lasting seven to ten days: occurs without pain. She has been able to work until her present sickness, which began fifteen weeks ago, when she suffered pain in the lower part of the abdomen, particularly in the hypogastric region. This has been greatly increased by pressure; appetite has been poor. She has been treated during this time for a quite severe bronchial attack attended with a hard, painful cough. I saw her yesterday for the first time in the ward. As I expose the abdomen you will notice that the lower portion of it is a little more prominent. In palpating over the abdomen I have to exercise the greatest care on account of its being so tender. This mass extends to about the level of the umbilicus. It is situated in the central part of the lower abdomen, extending equally distant on either side of the median line, consequently is a symmetrical tumor. Now, it is important to remember in connection with this distension, that there has been a continuance of her menstruation and that during the last few months when this tumor has been increasing in size, the menstrual flow has been excessive, almost hæmorrhagic in character. There is no variation in its occurrence from the normal periods, but the duration is longer. As I make pressure over the lower part of the abdomen, I find it exceedingly tender. The patient is very nervous and consequently contracts her recti muscles. Examining in the ward yesterday I found

*Delivered at the Philadelphia Hospital, October 8th, 1892.

that the finger could be pressed between the mass and the symphysis, and in examination of the vagina, the tumor was apparently continuous with the uterus, forming an angle between the anterior wall and the cervix, showing that the development was in the uterus itself. From what I said to you in the last lecture upon the subject of the diagnosis of abdominal conditions, you will recognize this trouble must come from some disordered condition of the viscera situated in the lower portion of the abdomen. Now, a growth of this kind consequently, might be in the uterus, the tubes, the ovaries, or from malignant disease of the rectum, or of the retroperitoneal pelvic glands. Finding the disease situated in this part of the abdomen, it became a serious question to decide as to which particular organ has been the source of its development, and to arrive at some idea of the subsequent progress of the condition. This knowledge will be of advantage in determining whether interference shall be instituted, and when it should be done.

If the tumor arose from the ovary we would expect to find at this period of this growth that it would be situated lower down in the pelvis; more to one side than in the central position. It would more than likely present a certain sensation of fluctuation or at least elasticity, and not the dense, hard feeling that is presented by the mass now under observation. It is true that we may have solid tumors of the ovary, either fibroma or sarcoma, but such growths would without question be situated lower down in the pelvis and to one side of the uterus. The uterus could be outlined and separated from the growth, unless it was closely attached to it; even in such cases the uterus could be felt upon the tumor, rather than forming a part of it. An ovarian fibroid, and more particularly the sarcoma, is likely to give rise through its pressure upon the pelvic vessels, to accumulation of serum within the pelvis and abdominal cavity; in other words to an ascites. We remember, also, that the ovary may be the seat of a growth known as a dermoid tumor, which from its contents presents a sensation of considerable resistance and may be mistaken in those cases where it is closely attached to the uterus, for a fibroid growth. Where the tumor is closely attached to the uterus, so much so as to be difficult to be separated from it, we will find it situated to one or other side or posterior, while the mass we have in this case seems to develop more particularly in the anterior wall of the uterus and project in front of the cervix.

The dermoid cysts already mentioned arise from folding in of the epi- and mesoblasts in the embryonic life of the individual, and the presence of these abnormal tissues may result through the slightest irritation, in the development of large tumors. The cysts may occur at any time in life, as I recently removed one quite large in size which involved both ovaries from a girl of eleven years. They are seen also in women as old as seventy. Where these tumors are situated beneath the broad ligament and push it up in front of them, the diagnosis may be extremely difficult to determine between them and tumors situated in the uterus itself. We are only able to determine, by careful observation of the peculiar sensation presented by the tumor and by its situation.

In the patient before us we find the tumor is situated anterior to and projects over the cervix, consequently we are not likely to have an ovarian tumor, or a tumor developing from the broad ligament, as these would assume a different relation to the uterus itself. That it is sometimes exceedingly difficult to determine ovarian tumors from those involving the uterus is self-evident. In this hospital some years ago I had a patient under my charge, in whom there was a development of a tumor in Douglas' pouch, which had pushed up the uterus and bladder in front of it and in its enlargement had displaced downward and forward the posterior wall of the vagina until it projected, a large surface, from the vulvar orifice, pushing the posterior wall of the vagina with it. In introducing the finger to reach the cervix it had to pass over this mass, which was elastic and not hard. The tumor had pushed the uterus and bladder up to such a degree as to interfere with the evacuation of the latter organ. The posterior wall was rendered so tense that it seemed to be continuous with the uterus and hence diagnosis was made of possible fibroid cystoma. The patient died two days later from pressure upon the pelvic viscera, when an autopsy disclosed that the tumor in the pelvis was an ovarian cyst which had formed extensive adhesions and had developed to considerable size in this situ-

ation. The contents of the ovarian cyst were thick and viscid. It was firmly adherent in the pelvis, and could have been readily emptied through the vagina and the cyst wall thus enucleated without any difficulty to the patient.

A case comes to my mind in the practice of another physician in which the patient had a tumor, with the abdomen symmetrically developed. The tumor had remained in existence about eleven months. During this entire period she had not menstruated. Palpating the abdomen, a sensation of elasticity could be determined without fluctuation. On sight this tumor was so tense as to leave us in doubt whether it might not be a distension of the uterus; this, taken together with the fact that the woman had not menstruated led us in spite of her denial to consider pregnancy as a possibility; but upon exploratory incision, the glistening appearance of the surface of the tumor disclosed that it was undoubtedly ovarian. Even vaginal examination was insufficient to enable us to determine distinctly that the tumor was separate from the uterus. Exploratory incision was made which revealed a glistening surface of the tumor and at once impressed us that we had to deal with one which had originated from the ovary. A trocar was plunged into the tumor without procuring a drop of fluid. The opening was then enlarged and the tumor turned out and proved to be an ovarian tumor and subsequent examination disclosed the fact that it was a tumor made up of an immense number of small cysts, apparently a tumor in which every Graafian follicle had undergone cystic degeneration, and these enlarged follicles contained within the sac formed the tumor itself.

In tumors of malignant character, the relation to the uterus is sometimes so close as to render it possible to determine their character only by exploratory incision. These cases, however, only accidently come under consideration at this time, for the reason that here the tumor is situated anterior to the uterus, or folds over the cervix, and consequently we must exclude the possibility of it being ovarian, and for the same reason we would eliminate tubal tumors. In tumor of the tube, it is generally elongated as well as enlarged. The history does not present the symptoms of suppuration, hence we narrow down the possibility of the growth in this individual instance to that of tumor of the uterus, or one which may develop in its immediate proximity. In this respect we should not forget that we have tumors in the retroperitoneal glands which may attain to as large a size as those involving the uterus. Retroperitoneal tumors are rare, but that they do occur, however, I have found in a recent case to my cost. The patient was a woman eighteen years of age. She came into the Jefferson Hospital a short time ago with her abdomen quite largely distended, and with a history of trouble having occurred some nine years ago following an attack of mumps. It was a very natural inference that there had been a metastasis of the mumps to the ovaries and that this patient had developed an ovarian tumor as a result. It was possible the tumor might be one of the dermoid variety. It felt like a dermoid for the reason that sensation of fluctuation was indistinct, one of elasticity rather than fluctuation. But such tumors are found posterior to the uterus, while we find in this patient the posterior fornix is free. The tumor just described was not very movable, which is not surprising in a young woman in whom the muscular structures are firm. Vaginal examination or rectal examination was not made. As I look back over the case from a later history, I do not see where either would have afforded any special advantage in determining the character of the growth. The abdomen was opened with the expectation of removing an ovarian tumor. As soon as the peritoneum was opened the appearance of the tumor—more or less lobulated—led me at once to realize that it was not an ovarian. A trocar was plunged into it, presenting a sensation of fluid within it. It was so elastic that we could not believe that it did not contain fluid, possibly of a thick and viscid character. Not a drop of fluid, however, came through the trocar. The abdominal incision was then enlarged and the tumor drawn out. It was found that it was held down by the peritoneum at the level of the base of the pelvis, the peritoneum projecting over it upon each side. The uterus was attached at its anterior surface and lifted to a considerable extent above its ordinary level. It was drawn out and lengthened as the result of the growth of the mass. The peritoneum was cut through just behind the uterus and the latter very quickly torn

off from the surface of the tumor. Passing the hand behind the uterus it went into the structure of the mass and the upper part of it was torn through; following the uterus down, the inferior mass was enucleated or shelled out, showing a large granular mass. The pelvis was carefully cleaned and packed with iodoform gauze, stitching the peritoneum with the upper part of the sac about it in a way that the discharge could not enter the peritoneal cavity. The patient only survived the operation a fraction of an hour. In this case vaginal examination would have disclosed but little, as there was no way in which we could have told that the tumor was situated posterior to the peritoneum until an exploratory incision was made. Even vaginal examination would have led me to suppose that I had to deal with an ovarian cyst with thick, viscid contents that had developed in the pelvis, had increased in size and through its attachments to the uterus dragged that organ up with it. Such tumors are exceedingly rare.

Vaginal examination in the patient before us discloses the fact that we are able to pass the finger behind the uterus and that the mass is continuous with the cervix posterior and anterior, so we exclude the possibility of this being a retroperitoneal tumor. Now tumors that occur in the uterus you would recognize are those more particularly of the structure of the uterus itself and hence are known as fibroid or myomatous tumors. They are due to some local irritation of tissue in the uterus, which develops more rapidly than the other portions of the uterine structure. The connective tissue becomes thickened until the tumor itself is more or less isolated from the remaining structure of the abdomen, having a distinct capsule. The tumors of the uterus differ somewhat in their histological structure. Thus, we have some in which the tumor attains to large size, is quite elastic, does not give a sensation of resistance and density, in which the structure of the tumor is similar to that of the uterus, consequently they are known as myomata or soft fibroids. Where the tumor is of slower growth it pushes about the connective tissue which forms a capsule from which the tumor can be readily enucleated. These are tumors which have become mature. Fibroid growths may occur singly or more frequently in groups, or a number of them in the same uterus. They vary in size from a millet seed to those weighing nearly a hundred pounds. Such a tumor as it increases in size is a source of discomfort to the patient, gives rise to organic changes in the structures whose functions are interfered with. A tumor in its early development may be pressed down into the pelvis giving rise in this way through pressure to interference with the action of the bowels and rendering voiding of urine difficult if not impossible. Indeed, many cases are discovered through the effort at at emptying the bladder in cases of urinary retention. Tumors of the uterus are also divided according to their situation in the structure of the organ; thus, those tumors which have their origin in the layer of the muscular tissue near to the peritoneal surface, are crowded out beneath the peritoneum as they increase in size, and become known as subperitoneal fibroids.

On the other hand, if they are situated near to the mucous membrane of the uterus and its cavity, as they increase in size they press into the cavity leading to the formation of a tumor known as submucous, which may be a polypus or a growth having for its attachment or base the entire wall of the uterus, when it is known as a sessile tumor. Those tumors which are situated in the wall of the organ equally distant from the mucous and subperitoneal surfaces form what are known as mural or interstitial tumors. These divisions, then, into submucous, subperitoneal, and interstitial tumors are not variations in character, but are only used to distinguish their situation and relation; they are all histologically the same. Upon the situation of the tumor will depend the subsequent symptoms arising from its presence. One which occupies the cavity of the organ and is pushed into it, will often-times distend the cervix and lead to its expulsion from the cavity of the organ. These growths distend the cavity of the uterus and are covered with the mucous membrane which they carry before them. This membrane becomes thinned, the vessels attenuated or varicose, the surface of the mucous membrane is ulcerated and the patient consequently is likely to suffer from hæmorrhage. First, the periodical flow will be greatly increased, last a number of days; later one will find the patient bleeds upon the slightest irritation. In such cases hæmorrhage is a marked symp-

tom. It may occur as an aggravated flow or take place during the intervals. I am inclined to believe that the tumor in the present instance is an interstitial one involving the greater part of the anterior wall of the uterus; this for the reason that it is found to project over the cervix. If it were situated in the posterior wall it would very likely lead to retroversion of the uterus. The tumor, however, of late has begun to encroach upon the mucous wall of the uterus, interfering with the circulation and consequently caused a prolonged menstrual flow, gradually increasing and at times quite free. The only condition with which this might be confounded would be that of pregnancy; the existence of menstrual flow is not necessarily a contra-indication, for it must be remembered that some women continue to menstruate during the entire period of pregnancy. I have a patient who, for several years, has believed herself pregnant whenever she has an excessive menstrual flow. This is the first indication of her pregnancy and for the first three months she is subject to more or less hæmorrhage at the time she should menstruate.

I remember, during my term as resident in this house, a woman who menstruated regularly during the entire period of her pregnancy and gave birth to twins.

Pregnancy is eliminated in this patient for the reasons, first, that there is an absence of any history, and second, this hæmorrhage has been going on for a number of months longer than we would expect it should for so slight a distension of the abdomen as is here present. Then, again, we do not have the physical signs of pregnancy in the uterus itself. The uterus is firm, more tense than is the pregnant uterus. Then palpation and auscultation will serve to complete the diagnosis. We are forced to the conclusion that we have to deal with growths in the uterus and that the immediate growth is mural or interstitial. As the tumor increases it will give rise to more or less discomfort. It will press upon the structures about it. The size to which the tumor has attained and its situation is such that it is not likely to give rise to the same pressure upon the pelvic viscera as if it were situated lower. As they increase in size, however, they give rise to pressure upon the intestines and blood vessels, the latter causing changes necessarily in the structures supplied by them. They not unfrequently press upon the ureters running into the pelvis upon either side and this pressure gives rise to distension of the tube, later to distension and destruction of the kidney structure. I have seen instances in which the kidneys have become sacculated as the result of such a pressure. It was a wonder that the patient had been able to survive with such a marked diseased condition.

We come now to the consideration of the question as to what should be the course of treatment in such a case. Shall the patient be subjected to an operation which shall remove the uterus itself, or shall we be content with the removal of the ovaries, or simply treat the symptoms, making her if possible more comfortable, or shall we instead attempt to remove the tumor through the uterus itself? These questions present themselves for our consideration and determination. Medical treatment in such cases has been unsatisfactory; the remedies which have most effect upon the growth are those known as the oxytoxics; that is, remedies which cause contraction of the uterus, such as quinine, ergot, extract of cotton root, and remedies of a similar character. Of these, ergot exerts the most beneficial influence and acts in two ways: first, by causing contraction of the muscular fibres of the uterus itself, and thus decreasing the amount of blood sent into the organ and increasing the ability of the organ to extrude the foreign body from its walls and hasten the time when by this extrusion the tumor ceases to increase in size; second, it has an influence upon all involuntary muscular structures, in that way decreasing the amount of blood sent into the tumor itself.

Other remedies have been administered with a view of limiting the growth of the tumor by producing processes of retrogression similar to those which sometimes take place under the direction of Nature alone. The most important of these is that of the calcification of the tumor. The tumor becomes calcified by the deposit of calcareous material in its structure. An early lecture recounts numbers of cases in which the patients have had extruded from the uterus and vagina calcareous masses which were denominated as uterine calculi.

These, however, were simply tumors which had undergone calcareous degeneration and had been subsequently extruded. To accomplish this purpose, Sir James Y. Simpson proceeded to administer the chloride of calcium in large doses. It was soon found, however, that the action of this agent could not be confined to the uterus, but that it gave rise to deposits of calcareous material in the coats of the vessels and in the valves of the heart. In intrauterine tumors ergot exerts an influence in hastening the time at which the tumor is extruded from the uterus by dilatation of the cervix. It should be remembered, however, that ergot is not an absolutely safe remedy, as through its action it may lead to the too rapid extrusion of the tumor through the uterine walls, whether subperitoneal or submucous, and cause sloughing, with the development of septic symptoms, whether the tumor undergo necrosis or death in the uterus or in the abdominal cavity.

I have seen two cases, in one of whom I believe the extrusion to have taken place, so that the peritoneum and the tumor lost its vitality. The patient died from septic peritonitis. In another case the tumor was a submucous one, but had undergone loss of its vitality and produced considerable elevation of temperature. The tumor was removed, was found to be an offensive necrotic mass, and the patient subsequently died of septic poisoning. Recently a patient came under my observation, fifty years of age, suffering from profuse hæmorrhage which had occurred during the last year. The condition was such as to lead me to infer the possibility of malignant disease. Upon examination the vagina was found filled with a mass nearly as large as my fist. Passing the finger up to the cervix, which could be done with difficulty, it was found that the cervix encircled the projection. It became a serious question whether we had to deal with a polypus or an inverted uterus. Examination under ether, however, disclosed that it was a fibroid polypus hanging by a pedicle from the side of the cervix. It was twisted off and the patient has subsequently done well. Such cases have not frequently been subjected to manipulation with a view of the return of a supposed inverted uterus which was subsequently found to be a fibroid polypus. In the cases in which the tumor is extruded from the uterus, there is not a question of doubt as to how the mass should be treated. Where the tumor is situated within the uterus, and the cervix can be dilated, it should be separated from the wall and twisted out. Where the cervix is as yet undilated, the question becomes one of considerable interest and if it is found that the tumor has no pedicle and is situated in one wall of the uterus as a base or projecting into the uterus, it becomes a serious problem how it shall be treated. If the tumor is not too large, the cervix may be dilated and split up on either side to the vaginal fornix when the dilatation will be more rapidly accomplished. The tumor is seized with a firm pair of forceps, preferably a Volsella, and then with the finger enuculeation is accomplished as far as can be reached. This should be followed by grasping the tumor, twisting until it is turned out of its bed, or the enucleation may be accomplished by the use of the serrated spoon curette of Thomas. These are cases in which the operation is attended with the greatest difficulty and considerable traumatism of the cavity of the uterus. The large cavity left by the removal of the tumor is likely to fill up with blood and subsequently become infected, consequently renders the plan of procedure exceedingly dangerous. It is very undesirable to leave the uterus to fill up by clots of blood. The preferable plan of procedure would be to pack the cavity of the uterus with iodoform gauze. The end of this may be left out of the cervix, and the cervix, where incision has been made, may then be removed at the end of forty-eight or seventy-two hours and intrauterine irrigation is practiced, taking care to afford opportunity for a return flow of the fluid. If the cervix is not sufficiently dilated to permit of the extrusion of the tumor, the latter is dragged against it and held with firm pressure. The cervix will be found to slightly dilate and permit the extrusion of a very large tumor. The gauze packing before mentioned in these cases serves a double purpose; it acts as a drain, by its presence as a foreign body, stimulates the contraction of the uterus, and promotes the elimination of septic material through the activity of the transudation of serum toward it. The treatment in those cases where the tumor has attained to considerable size, I hope to discuss before you in a subsequent lecture.

Communications.

CROUP, DIPHTHERIA AND SCARLET FEVER.*

By F. LEONHARDI,
DRESDEN, GER.

These three diseases have attracted my special attention for some time past. In 1854 I presented a communication before the Dresden Gesell. f. Naturn. Heilkunde, on the subject of Tracheotomy in Croup, after my first successful operation in 1852 done for croup (the sixth at that time done in Germany). In 1888 I combined Croup and Diphtheria in an article and 1891 I gave my views on Scarlet fever, and it is now my purpose to combine my knowledge of all three diseases in one communication.

The question so often discussed, that the old Laryngeal Croup, the Angina membranacea, Agnina couenneuse, and the Diphtheria, which has made its habitat among us since 1862, are one and the same thing, the only difference being the grade of infection and the organs attacked, I cannot accept. *There always were and there are yet, cases of pure inflammatory croup*—non-contagious, brought about by local irritations of the mucous membranes by cold, wind, chemical irritants, etc., for instance, hydrochloric acid fumes, strong ammonia, etc. It originates in the larynx and extends to the air passages, may take a rapid or slow course accompanied by catarrhal fever. Tracheotomy produces better results in these cases than in diphtheria, I have performed this operation in eleven cases of inflammatory croup with five complete recoveries; in diphtheria the mortality rate is higher. Inflammatory croup was described first by Francis Home, 1765. Broussais, in 1829, opposed Bretonneau's theories regarding its identity with diphtheria which has since been accepted by more recent writers and practitioners, Henoch, Waldenburg, Oertal, Francotte, etc. Virchow recognized as early as 1847 anatomical differences between the croupous and diphtheritic membrane, and in 1865 declared the two diseases to be totally different. The occasional appearance of whitish or yellowish patches on the fauces or tonsils in inflammatory croup does not always change to diphtheria.

In the Children's Hospital of Dresden, Dr. Kuther reports (in 1845) in 20 years 35 cases of true croup with 20 deaths, 13 recoveries. Contagion was never observed. I myself saw in 1852 two children in the same family suffering from croup, the youngest died, the elder was saved by a tracheotomy. Dr. Palloni reports a fatal case caused by inhalation of hydrochloric acid fumes. An unmistakable case was seen by me in 1871 in a young man of 22 years who had taken a severe cold in riding to extinguish a fire on a cold night in February; it became necessary to perform tracheotomy on the fifth day of his illness, on the eighth day he was able to leave his bed.

Dr. John, of Dresden, has shown that among animals inflammatory croup often follows an exposure to the heat and smoke of large fires.

Inflammatory croup seems to have occurred more rarely in Germany since the epidemics of diphtheria have been on the increase, but I have met with unmistakable cases in 1868, '71, '75, and in the winter of 1891 and '92.

Laryngismus Stridulus can be differentiated from the true croup in that often a mild emetic, sometimes only a warm drink will shortly relieve the symptoms of dyspnœa and in a few days the cure is complete. In true croup, however, there a persistent fever, obstruction of the air passages, and more or less dyspnœa, this latter influenced by the expectoration of membraneous shreds of a yellowish color mingled with the mucus.

The treatment consists in local bloodletting in the cases of well nourished children when the fever is high, and the administration of 5 to 10 centigrammes of calomel hourly. This latter is especially preferable to the use of emetics, and if blood letting is resorted to it should be done early in the disease, later it would not only be useless, but might do much harm.

In mild attacks in weak subjects, one dose of infusion of ipecac, or tartar emetic in small doses, is indicated, but great care should be used in repeating such doses; solutions of copper or zinc should not be used. Pure moist air and ingestion of large quantities of warm water are indicated. External applications consist in the Priessnitz—water dressings around the

*Abstracted and translated for Med. and Sur. Reporter by Marie B. Werner, M. D.

throat or a linen cloth soaked in olive oil. Further treatment consists in 3 centigrammes of calomel every four hours either alone or combined with 1 centigramme of sulf. antimon. aur. (German pharmacopœa) until the exudates become loosened, also an emulsion of amygdalæ with sod. bicarb.

The violent attacks of dyspnœa and continuous desire to cough, I was able to combat successfully with small doses of morphia; if this fails, tracheotomy is indicated.

Diphtheria.—The epidemics and contagion of this disease depend upon the Klebs-Loeffler bacillus. It is, according to Oertel and others, first a local disease, located in the posterior fauces. The time of incubation, from the time of exposure to the appearance of the fever, has been usually 5 days; in this Oertel agrees with me. The usual statement is from 2 to 16 days; some think it may even exceed this number. Close observation has shown that the formation of the membrane on the tonsil and other portions of the post pharyngeal wall is the first indication of the disease. This proof of its being at first a local disease conduces to raise the hopes in many of using local applications to destroy or dissolve the membrane, and in this manner cut short the disease by destroying the bacillus. Many cauterants, astringents, antiseptics, etc., were tried. The first proved to be useless and sometimes harmful, since it was not always possible to confine them to the affected area, but also exposed more surface to the contagion. As soon as the fever has set in it has become constitutional.

Of the countless number of specifics recommended for internal administration, none have been found reliable at all times; it remains therefore for the physician to rely on rational empiricism for satisfactory and sure therapy. It is always necessary in all diseases to understand their regular course and how much nature may aid toward recovery. Dietl, of the Vienna school, has made the pregnant remark: "Nature alone can heal. We must always study first the boundary of Nature's activity. As long as we are ignorant of Nature's laws, so long will we remain ignorant of our duties as physicians."

The course of the disease if favorable toward recovery is usually marked by a high temperature on the first day, 39° to 40° C.; or it may increase to the third or fourth day; or remission setting in on the fifth day at this time the line of demarkation can be observed in the false membrane and in the infiltration of the mucous membrane; the final shedding of the membrane and necrosed tissues takes place between the sixth to the ninth or tenth day and not later than the fourteenth day. The temperature is usually down after the fifth day, but it has been known to rise again on the sixth or seventh day from 39° to 40° C. never remaining high long at time and ending with perspiration. The unfavorable cases, may be characterized from the beginning by the intensity of the attack, the amount of poison taken into the system producing extensive exudations after involving the deeper structures, thus gangrene of the entire tonsils, the uvula and a larger portion of the palate; this is rapidly followed by sepsis and heart failure. I have seen death follow such symptoms in three cases on the fourth and sixth day.

More often there is an irregular and more tedious course of the disease. This is observed in those of a weak, anæmic constitution, with unfavorable external surroundings or improper care during the first days; for instance, through a lack of recognition of the disease, the membranes may be shed too early, thus leaving a surface exposed, and in this way predisposing to an attack on the deeper structures. This is shown by increased enlargement of the lymphatics. The fever is usually high; sepsis often sets in; changes in the blood and muscles, particularly fatty degeneration of the heart muscles, occur; there is albuminuria, and changes take place in the internal organs. Recovery is slow and protracted, the kidneys may be troublesome for some time, anæmia is persistent, paralysis sometimes forms a troublesome complication, often death follows through contraction of the air passage or from heart failure; this latter condition is shown by a sudden decrease in temperature with a rapid pulse. Fever lasting beyond the eighth or ninth day denotes some deep seated complication. Quinine, antipyrin and other antipyretics are not only useless in the first week but may do positive harm.

Since I have become convinced that the disease cannot be kept from becoming constitutional I have been in the habit of

using, sod. nitrate, sod. bicarb. of each 3 to 4 grms. added to 150 to 180 of aqua dest. and 20 grms. of mucilage of acacia or syr. of althea. M. Sig. Dose for adults a tablespoonful; for children a teaspoonful to half a tablespoonful according to age. With high temperature and congestion of the head, give dose of calomel; this was first recommended by Volguarts and it has not only been my experience but also that of others, that it acts as a good febrifuge and aid to the excretions, acting particularly on the kidneys. I hold that it may have also a local action, possibly in loosening the membrane.

In addition, Port or Hungarian wines are found useful after a few days. In the weak, or when the temperature is low, one can begin at once with this form of stimulation. The anæmia receives later etherial tincture of iron or quinine, and citrate of iron dissolved in Spanish wine. Sepsis may be combated with solution of chlorine water or by the mineral acids.

The diet during the first week consists of weak broths, milk and softened toast or roll, large quantities of water and weak tea. Milk given in small and repeated doses, I do not consider good, as it readily upsets the stomach, and that which remains in the back part of the throat forms a good soil for the proliferation of the bacilli.

Of great importance is the local treatment of diphtheria. I have alluded to the impropriety of the use of caustics and the attempts at removing the membrane by chemical means as being easily followed by deeper complications.

In place of ice or inhalations I have used oft repeated luke-warm injections, using a syringe holding fifty grammes of fluid. The patient placed in an upright position, a towel pinned around the neck and a basin in front, the injections are made into both nose and mouth, the water allowed to flow into the basin—three or four syringefuls each time, and repeating every two or three hours. The fluids used are either chlor. potass. ten grms. aq. destil. 160 grms., mel rosae 15 grms., diluting this mixture; or I advise a two per cent. sol. of potass, chlor., the utmost care being exercised in instructing the mother or nurse in regard to its use. I do not advise painting the throat with any of the many solutions in use.

Society Reports.

THE MEDICO-CHIRURGICAL SOCIETY OF LOUISVILLE.

Stated Meeting, Sept. 2, 1892.

The President, Dr. F. C. Simpson, in the chair.

OPERATION FOR VARICOCELE.

Dr. W. L. Rodman: Mr. President—This patient (presenting case in person) had a well-pronounced varicocele on the left side; was advised by his family physician to have an operation done, and was referred to me. After purging him very thoroughly for several days, I sent him to the Norton Infirmary, then cut down upon the veins and removed a section about one and one-half inches in length; brought the cut ends of the veins together, uniting them by means of a continuous suture of Chinese silk. The case has done very well from the first, none of the symptoms usually following this operation presenting themselves. Operation done two weeks ago.

I am indebted to Dr. Palmer for a valuable suggestion in connection with the case; that is, first purging and then locking the bowels up and keeping them so for at least a week after the operation. His bowels, I think, were allowed to act on the sixth day, at which time the dressings were changed for the first time. You will notice the wound is healed very nicely, leaving only a small scar. There would have been no scar at all, except for the fact that I left a small opening at the upper end and lower end of the incision for the purpose of drainage; I think, however, this was hardly necessary. Another time I shall not provide for drainage, and bring the wound entirely together. I think it is advisable in these cases for the patient to wear a suspensory for at least sixty days after operation, especially in the summer time.

DISCUSSION.

Dr. A. M. Cartledge: There is one feature that strikes me particularly about this case and the excellent results, and that is the suturing of the veins together in order to lift up the testicle. That is the trouble I have found with varicocele operations, the scrotum has become very

much elongated and I have never carried out the varicocele operation taking out a piece of the scrotum, as has been suggested in practice. My results in operations for varicocele have not been as satisfactory as I would like, and I think the method employed by Dr. Rodman of suturing the veins is a very valuable additional step in the operation.

Dr. E. R. Palmer: I want to congratulate Dr. Rodman upon the excellent results following the use of iron dyed silk sutures and their incarceration, without any trouble, in place of the catgut that we have been having such bad experience with. The preparation of the patient for operation in cases of varicocele by first purging followed by confining the bowels for eight days is recommended by Gerster, the idea being that there is danger of fecal infection, and that the suppuration which nearly always follows the operation is due to that cause. Gerster makes a very strong point of this fact, and advises that the bowels be kept closed until the external wound has healed; his suggestion of eight days is, of course, the maximum length of time.

Dr. Wm. Bailey: I would like to ask how the wound becomes infected from the bowels.

Dr. E. R. Palmer: It is a well established clinical fact that it is impossible to prevent the distribution of poisonous material from the feces to the neighboring parts if the bowels are active.

Dr. A. M. Cartledge: I would like to ask Dr. Palmer a question: Some two weeks ago, I saw a most remarkable case of varicocele; patient was a boy about seventeen years of age who thought he had hernia. The testicle on the left side was atrophied to such an extent that you could scarcely feel it, seemed to be about the size of an ordinary bean, with an enormous varicocele on the right side. The question is if an operation is performed on the left testicle how much development will take place in the testicle? Also why varicocele occurs with greater frequency on the left side?

Dr. E. R. Palmer: I think the testicle is practically gone, and you ought to have a double operation to preserve the other testicle. The most extensive case of varicocele that I have ever seen was one which came under my observation a short time since in a rape case. There was an entire disappearance of both testicles in the defendant, simply an enormous bag of veins on each side. The case was, on my testimony, dismissed as one of blackmail.

Varicocele occurs on the left side more frequently than on the right, because of the long vein on that side and the manner of its termination—purely an anatomical reason.

PATHOLOGICAL SPECIMENS.

RICE SEED BODIES.

Dr. A. M. Vance: Mr. President—The first specimen I exhibit is a collection of the largest rice seed bodies that I have ever seen; they were removed from a man, a glass-worker, in Indiana, who, for two years has had developing upon the dorsal surface of his right hand, a large diffuse ganglion. I laid it open from the base of the first phalanx of the middle finger and half way up the forearm, turning out nearly a pint of these bodies, besides quite a quantity of milky material. It was very difficult to scrape them out of the ramifications of the different tendons. The wound healed by primary union, and the man has a very useful hand and arm.

STRANGULATED FEMORAL HERNIA, RESECTION: DEATH.

About the middle of July I was called to see a young lady in the morning, who gave the history that for two years she had been under treatment of a "Rupture Specialist," and had worn one of his trusses; that some months before I saw her, he had advised removal of the truss from a right femoral hernia as she was cured. Eight days before I saw her the hernia had come down and had become incarcerated. He and a professional friend put the patient under chloroform, and, after considerable manipulation, stated that the hernia had been reduced. The patient went home and called the family physician, who treated her one week, feeding her by the rectum. About this time her physician left the city, telling her she would get along all right. The next morning I was sent for, and found the woman about twenty-five years of age, very hysterical, rapid pulse and a large tumor in Scarpa's space; I advised an immediate operation, as I believed it to be an irreduced hernia. However she told me that she had had an action of the

bowels each day that week. She failed to state that she had been fed by the rectum. I operated with the assistance of two trained nurses, Dr. Guest administering the chloroform. I found this portion of the ileum gangrenous and ruptured, and found probably a pint of feces in the sac when I opened it. I determined to endeavor to resect, as the old operation of an artificial anus is a thing of the past. I resected about an inch of gut, doing Wolfler's operation, sewing it together by a continuons Lembert suture, inverting the peritoneal coating, so as to get perfect apposition. The young lady did well for two days; had two evacuations of the bowels, but died at the end of sixty-two hours of septic infection from the foul condition of the wound. I feel sure that the operation of resection was a perfect success, and have been pleased to see that Dr. Ransohoff, of Cincinnati, also advocates primary resection in all cases of gangrene of the intestine from strangulated hernia.

APPENDICITIS: OPERATION.

About eleven days ago I was called to see a gentleman forty-two years of age, with Dr. A. M. Goodman; the history was that he had been quite constipated ten days before. He had succeeded in getting a movement of the bowels, but continued sick with considerable pain, for the first days of his illness, being particularly referable to the region of the appendix. However, when I saw the patient, there was no severe pain or tenderness over that point, and no marked tympanites; but there was some swelling just below the ribs on the right side, and, upon deep pressure, some tenderness. I advised that operation be delayed for forty-eight hours and see what developed. On the morning of the second day thereafter, I was again called; found the man with high temperature, delirious, etc. Dr. Bodine was also called in consultation at this time. We made an incision three inches long on a level with the post-peritoneal space so that drainage could take place there; evacuated a large quantity of thick very offensive pus, and introducing my finger I drew out two little casts of fecal matter about as large as a lead pencil and two inches long. I then irrigated the cavity and in addition to the fecal matter which came away with the irrigation water, we found this membraneous looking affair that you see here, which upon examination, proved to be the appendix vermiformis. The case has progressed very favorably since that time; the delirium left him in a few hours, and be has been perfectly rational and free from fever. The wound, now, after eleven days, has healed and the cavity is closed up. Evidently when Dr. Goodman first saw the patient, there was a circumscribed abscess around the appendix, which later ruptured into the post-peritoneal space, while the patient was lying on his back, proving positively that the appendix sloughed off into the post-peritoneal space, a question which has been in doubt. I failed to state that since the operation, and before closure of the wound, a considerable quantity of material looking like coffee grounds has come away; also a piece of egg shell about half the size of your finger nail.

RESECTION OF COCCYX.

The next specimen is a coccyx removed from a young lady seventeen years of age, who gave the history that six years ago when she was eleven years of age, she had a chair pulled from under her, allowing her to fall upon the floor causing considerable pain. In the last two years only, has she been seriously inconvenienced by pain and tenderness in the sacral and spinal regions. She had been treated by several physicians and a spinal brace had been recommended by a so-called "Surgeon" in town. Upon examination it was found that the coccyx presented at right angles toward the rectum, and was perfectly movable. It was removed quickly through a very small incision. I did it by first cutting through its junction with the sacrum, dissecting down around it without making the large opening that is ordinarily done.

BOWEL OBSTRUCTION: OPERATION.

Here is a little specimen which does not amount to much as far as appearance goes, but seems to have played a very important part in the case in question. The patient was a young lady twenty-five years of age, with history that on Friday afternoon she had an eating match with her sister to see which could get away with the greatest amount of grapes, afterward eating a musk melon apiece. Friday evening she was

taken with great pain in the abdomen referable particularly to the region of the umbilicus. She began vomiting about the same time, which continued until I was called to see her. On Saturday about twelve o'clock it became fecal and continued so all day Sunday and Monday. When I saw her Tuesday she was still vomiting fecal matter, the family in the meantime had been giving her considerable milk, which was mixed with the material evacuated from the stomach, in a curdled state. Upon examination I found the abdomen moderately tympanitic, but no cake, however, very tender and painful on pressure; temperature 100⅗° F., pulse 120. I recommended an immediate laparotomy, which was consented to, and with the aid of Dr. Forwood and two laymen as assistants I did the operation. When I reached the interior of the abdominal cavity, I could discover no particular morbid condition; I then began to read the distended ileum. I had probably read about two-thirds its length, when in trying to raise it further, something gave away. I found on this portion a marked constriction as if a half inch rope had been tied there for a long time. Just to the side of it was this little body, which seems to me to be a mesenteric gland: however I tied it off. It was evidently an attachment of some kind, possibly the appendix. The intestines immediately filled up below, and I milked the fluid from the distended portion of the ileum and closed up the external wound. The patient continued to vomit fecal matter for twenty-four hours after the operation, but in smaller quantities and with less frequency than before. Salines were administered by the mouth, which caused free movements of the bowels. I heard from the patient to-day, she is still alive and prospects seem to favor complete recovery.

CARCINOMA OF LEFT APPENDAGES AND UTERUS: OPERATION.

This specimen was removed from h maiden lady thirty-five years of age. Sae gives the history of having had painful mentsruation, pain particularly severe in the region of the left ovary, for twelve years. Eight or nine weeks before she called upon me, she had been attacked with nausea and vomiting which lasted three days. She states at this time the enlargement of the abdomen commenced. When I saw her the abdomen presented the appearance and size of about a six months' pregnancy, a curious feature of it was that the enlargement appeared to be general. If it was a tumor, the tumor was controlled by the abdominal contents, rather than the contents being controlled by the tumor, as is usually the case. It was impossible to make a diagnosis of cyst, that is, a differential diagnosis between cyst and abdominal accumulation. Dr. Bailey saw the case, also Dr. Hays. She was also put upon purgatives, rochelle salts being given in one-half ounce doses each morning for two weeks. After I saw her I put her to bed and she had partial suppression and retention of the urine, which required catheterization for two or three days. The only medication for two weeks was rochelle salts, digitalis and acetate of potassium. Two weeks ago last Tuesday at the Norton Infirmary I did an abdominal section, exploratory; found a tumor presenting, a very peculiar feature being that it was not entirely filled with fluid. It extended out into the loins, around everywhere, among the intestines and abdominal organs, without having any definite shape. It was punctured and about a gallon of fluid removed. The tumor was easily delivered, and found to be attached to the left horn of the uterus by a very small pedicle. The tumor evidently contained the left ovary and tube; a mass of very friable material was found at the point of attachment to the uterus. Fearing further trouble from the friable condition of the pedicle, I passed the ligature around a portion of the left horn of the uterus to be sure that it would lie in good tissue. The patient made an excellent recovery being able to leave the Infirmary on the tenth day after operation. Dr. Frank has made microscopical section of a portion of this tumor, the specimen being at present on the slide of the microscope for your inspection, and he pronounces the trouble carcinoma; also states that the carcinoma is mixed with uterine tissue, showing that the uterus is in a carcinomatous condition. The question now presents itself as to whether it would not be good surgery to extirpate the uterus per vaginam or otherwise. The fluid contained in the cyst was the ordinary coffee colored ovarian fluid, or such as we usually see in ovarian cysts. I will

further state that the uterus appeared to be perfectly normal in shape, size and condition, as was also the other ovary.

DISCUSSION.

Dr. John Howard: I have carefully examined the specimen on slide of the microscope, and think there is no doubt but it is carcinomatous in character; uterine structure is also plainly discernible.

Dr. A. M. Cartledge: I think the case of appendicitis reported by Dr. Vance is doubly instructive; it in a practical way proves what certain men who have paid a great deal of attention to this subject in the last two or three years have been claiming; that is, that all of the trouble in the region of the cæcum belongs to the appendix primarily, that the appendix is the offending organ. Here is a case that according to its clinical aspect would be called perityphlitis, and yet the history proves that the appendix sloughed off into the post-peritoneal space; showing that while the appendix is an intra-peritoneal structure, yet, under certain circumstances, it might find its way back into the cellular structure. I think it is an exceedingly interesting case, and take it that it will be a long time before we will see another case that proves as much as this one.

In regard to the last case reported by Dr. Vance—it is certainly a very unusual case. Her age is against cancer, and all the history makes it puzzling. If the microscopists prove that the trouble is of a cancerous nature, I think the indications demand an immediate hysterectomy. I should prefer the vaginal hysterectomy, and think the operation might prolong the life of the patient for quite a length of time. From the examination I made of the specimen, I think there is no doubt about its being a malignant disease.

Dr. A. M. Vance: As Dr. Bailey saw this case, I would like to ask his judgment as to the propriety of an operation, removing the uterus.

Dr. Wm. Bailey: The case seems to me to be in such good fix, that while it might be good surgery to extirpate the uterus, still I would be disposed to wait until there was some further manifestation.

Dr. F. C. Wilson: I think it very probable that the case of appendicitis reported by Dr. Vance was caused by grape seed. I reported to this society several years ago the case of a little girl who had appendicitis, later dying from general peritonitis, caused by swallowing blackberry seeds. In the same family there occurred about ten days ago another similar case, the result of swallowing grape seed. The patient had been ill several days before I saw him; I recognized the features of it, and told the family my suspicions. I asked Dr. Dugan to see the case and agreed with him in advising an immediate operation. This was done, and the appendix was found to be perforated, and a collection of matter was found in the neighborhood. This was evacuated and the wound properly dressed. The patient, however, died in about thirty-six hours after the operation.

The question arises in my mind whether the result in the case reported by Dr. Vance would not show that there is possibly less danger in allowing these cases to take their own course, the appendix often sloughing off making its way backward through the posterior opening, rather than opening in front through the peritoneum, as was done in the case I have mentioned. In this case the peritoneal cavity was opened, for the reason that the abscess could not be reached by any other means, and, I think, possibly the manipulation and exposure contributed something toward infecting the general peritoneum. It is a question whether nature's course would not be the safest of the two. That is, it might often be better to wait and let the matter gravitate backward into the post-cæcal space.

Dr. J. G. Cecil: In reference to the last case reported by Dr. Vance all authorities, I believe, are agreed that the operations for removal of cancerous womb depend upon the extent of the involvement. If the cancer has extended to the womb, I think there is very little hope in any operation, except complete removal, no matter how it is done. It seems to me the determination as to what should be done in this case, would depend upon two things; first, what the exact relation of this growth was to the womb, whether it were part of it or not; if it is a part of it, then evidently the womb is cancerous, and, of course, if the involvement does not extend to any of the attachments or any of the surrounding organs, then hysterectomy I think would be the thing to be done. If, however, after this has been done any of the structures which are adjacent to the

womb have been infected by contiguity, then the operation would be of no avail. In other words, if the cancerous growth extends to structures outside of the womb, and its attachments, then the operation would promise no relief, and I think the woman would in all probability live longer without operation than she would with it. It, of course, is a very difficult question to decide exactly where the limit of this growth is. If it is confined to the womb, then remove the womb; if it is outside of it (and apparently it was outside of it), then it seems to me that the indications are not so favorable for operation.

Dr. A. M. Vance: This body which you see here was separated by a small pedicle from the uterus; this body however was very friable and the uterus was lifted up when the ligature was applied, and about three-fourths of an inch or more of uterine tissue was tied off. In other words, the section made to remove this growth was through uterine tissue. Dr. Frank asked me at once when he was preparing the microscopical section if I did not remove the uterus, as there were evidences of uterine tissue mixed with the carcinomatous cells. So, I do not think there is any doubt but there are cancerous cells in the uterus proper.

Dr. Wm. Bailey: In this connection, I would like to say that it was thought at the time of operation, that the uterus was about the healthiest thing we had about that neighborhood. If the disease is malignant, it has already invaded tissues beyond the uterus, and the removal of the uterus will not save the patient.

Dr. Turner Anderson; Concerning the last case reported by Dr. Vance. It seems to me it would be advisable to wait a little while before suggesting operation. It is true there is some risk in waiting, If the trouble recurs involving organs other than the uterus, then, of course, a vaginal hysterectomy would be out of the question, and the chances of giving the woman the benefit of operation would be taken away from her. The fact that the portion of uterine tissue examined contains evidences of carcinoma, is altogether in favor of vaginal hysterectomy. It is absolutely necessary that the uterus should be perfectly movable in order that vaginal hysterectomy may be performed. The liability to recurrence is very great. In one case which I saw quite recently, the bladder was wounded in the operation, a vesico-vaginal fistula was left, and in less than three months this fistula became carcinomatous. The woman is still living but has a very large and painful nodule in the bladder.

Dr. C. Skinner: In regard to the future of the last case spoken of by Dr. Vance. Unhesitatingly I think immediate operation is the thing to do. I would not delay the matter, just as soon as the patient's consent could be obtained, I would go ahead and remove the uterus, and the ovary and tube on the other side. I cannot agree with any one that it would be wise to await further developments; it may be too late for operation to promise relief. I think the woman will live longer and the chances of ultimate recovery will be greater by removing the uterus at once. As to the mode of procedure, I should prefer the vaginal hysterectomy.

Dr. H. M. Goodman: Referring to the case of appendicitis reported by Dr. Vance: I would like to hear one or two points discussed that I do not think have been brought out. One point raised by Dr. Wilson is the question of waiting; when I was called to see the case in question about the eleventh of August, I found the man complaining of constipation, pain over the appendix, temperature 103° and considerable tympany. I pronounced it by the old term perityphlitis. The case progressed very well for the first four or five days, then I considered that it was becoming surgical and advised the calling of a surgeon, and Dr. Vance was asked to see the patient about the seventh day. Two days before he saw the case, the pain in the region of the appendix had suddenly ceased. He was a little in doubt as to whether it was a case of appendicitis or not and so expressed himself; that it might be simple abscess, and advised waiting for forty-eight hours. Another point raised by Dr. Anderson as to whether the appendix is intra or extra-peritoneal: I remember in my dissections at the University, I opened somewhere about one hundred and fifty abdomens, and think I can safely say that in no more than fifty per cent. the appendix I noticed had a mesentery of its own; while in other cases the appendix was behind the peritoneum. In all cases where there is a mesentery, perforation is most likely to open into the peritoneal cavity. With further reference to the case under

discussion: I do not know why I insisted upon this man remaining in the dorsal position, but I did from the very start; whether this favored the gravitation of pus into the subperitoneal space or not, I do not know. But the question I would like to hear discussed more particularly is, whether as a general rule in cases of appendicitis, it is best to operate in the first three days, and what have been the results of such treatment. Surgery, of course, in these cases, offers the only hope of relief, and I think the case in question was simply a fortunate circumstance which we did not know had taken place.

Now, there are two forms of appendicitis; one which is a non-perforative variety, without suppuration and tends to get well by resolution, and is generally recurrent. The other form perforative appendicitis, with suppuration and often abscess or diffuse peritonitis. I had a case of this kind about seven years ago, a beautiful young lady who had recurrent attacks of typhlitis, some fifteen or eighteen in number, and she died. In all cases of recurrent typhlitis I think the operation for removal of the appendix indicated during the intermission. In cases of suppurative typhlitis I think the time for the operation can only be determined by the individual indications of the case.

Dr. F. C. Wilson: Now this raises another question in regard to the cases that happen to recover after an attack of appendicitis, possibly without suppuration, but recurring from time to time: I remember seeing about a year ago a little boy that I felt satisfied had inflammation of the appendix, and expressed my fears to the family, but resolution seemed to take place possibly without suppuration, and I heard no more of the case until I saw an account of the little boy's death, probably from recurrence of the same trouble. I have seen one other case within the last year that evidently was appendicitis, which recovered by resolution, but left considerable tenderness—Now is that boy to look forward to a recurrence of these attacks with a possibly fatal termination at some time, or, is it proper even after the case gets well, to perform an operation removing the appendix? Would that not be a justifiable operation, thus relieving the case of all future danger? Whenever this inflammation occurs once, is not the patient more liable to it afterward, so much so that the removal of the appendix would be justifiable?

Dr. H. A. Cottell: From the examination I made of the specimen under the microscope (section of tumor, Dr. Vance's case) I should not hesitate a moment in pronouncing it malignant growth, but, when it comes to the question as to whether it is really a carcinoma, I would not like to give a positive opinion without a further and more careful examination.

Dr. A. M. Vance: I would like to answer Dr. Goodman: In the East it is recommended that whenever McBurney's point is well marked, and the temperature exists forty-eight hours over 102° F, the case should be operated upon.

EXTIRPATION OF INGUINAL GLANDS.

Dr. W. L. Rodman: This specimen was taken from patient referred to me by one of the gentlemen present. He had several enlarged inguinal glands following the course of acute gonorrhœa. The doctor thought that he would be better off by having these glands dissected out, rather than to wait for them to break down spontaneously. I made an incision, and, in removing the glands, I found that this one had already undergone suppuration. I consider that I was very fortunate in being able to get it out without infecting the wound. I closed the wound with a continued buried suture of Chinese silk. The wound healed by first intention and the case was discharged on the third or fourth day after the operation. I think the patient was saved at least a month's suffering by dissecting out these glands. I have been doing this operation now for two or three years, and every time I do, I feel better satisfied with the result.

DISCUSSION.

Dr. A. M. Cartledge: My experience confirms the statement made by Dr. Rodman, that we do not remove enough of these enlarged glands, not only on the ground of saving a long convalescence, painting with iodine, etc., but they usually go on to suppuration, which can be prevented by early removal. The same thing is true of enlarged glands of the neck, whether they be tubercular, chancroidal, or otherwise.

Dr. A. M. Vance: My experience with enlarged glands, especially those about the neck has been quite different. I believe

when we cut down and attempt to remove the large number of glands in the neck, we do not get them all out. Manipulation seems to cultivate these glands. I had a patient not long ago with enlarged glands of the neck, and at the first operation I removed about twenty; in a short time they had reappeared, and I again operated, removing perhaps thirty more. The patient seems to be entirely well now. I have often worked on these cases for an hour, or even an hour and a half. I remember one in particular where I dissected enlarged glands for about an hour; after two or three months they reappeared seemingly as numerous as before.

Dr. A. M. Cartledge: I believe that we all profit more by our mistakes than by our successes. In connection with the removal of these glands about the neck; my early experience in the removal of these glands was similar to that related by Dr. Vance. I think if the Doctor in dissecting out these enlarged glands, would be sure to remove all the gland capsule, he would not have recurrence.

Dr. E. R. Palmer: I would hesitate very much about dissecting out chancroidal glands, because of the almost certainty of infection of the wound. I have had very little trouble from enlarged glands in gonorrhœa; I have dissected them out in a few instances, they were however adjacent to glands that had already suppurated and been opened. I, of course, would not molest the inguinal glands in syphilitic adenitis.

Dr. Wm. Cheatham: I have had in the last few months three cases of enlargement of the inferior maxillary glands, which I have treated in rather a unique way by the bougie; all three were cases of obstruction of the duct with retention of the secretion.

In some cases it is with much difficulty that the opening to Wharton's duct can be found; in one case by staining with a solution of fluoresine I was able to locate the opening. In another case the opening had to be slit with Bowman's knife, then a small Bowman's probe was passed and gradually increased in size until the duct was dilated; after this an eustachian bougie was used and passed to the gland, the secretion gradually emptied by gently milking and pressure. In those cases where there is much inflammation of the gland, hot applications should be made externally. With several days' treatment by this method the glands are easily reduced. One case recently treated in this way had been advised to have an incision made externally.

I am in favor of this operation for inlargement of these glands in preference to any external incision, as no scar is left.

Translations.*

M. B. WERNER, M. D.

To determine certainty of death in a cholera patient, Dr. A. Netter (*Rev. med del Est*:) Neither the arrest of respiratory movements or cardiac action are signs of death in a cholera patient. Claude Bernard has compared the asphyxiated stage of the patient to the winter sleep of the ground hog. The exhaled air contains no more carbonic acid gas than that which is inhaled; the arrest of the circulation is for that reason not a sign of death. The successful restoration of a patient in extremis, by intra-venous injections, necessarily establishes doubt. Netter proposes therefore in order to be certain of the death of the patient the following: 1. Through a stomach tube introduce a large quantity of fluid into the alimentary tract, the epithelial coverings having become so thin that there is a possibility of the water being absorbed. 2. Place the body in a warm bath. In the year 1846 a child of 6 or 7 years who was supposed to be dead was placed in a bath of 14° C. It raised itself up and spoke at the time; unfortunately it was taken out after a half hour and it was scarcely in bed when it died. The simplest method, however, would be to make a small incision through the abdominal wall in the presumably dead cholera patient and inject a large quantity of warm water into the abdominal cavity. This operation is a simple one and in case of restoration the results can be nothing but satisfactory since it has lately become customary to introduce large quantities of warm water into the peritoneal cavity during operation.

Some notes upon cholera in the pregnant are made by the principal physician in the State Hospital, Saratoff, Dr. Tipja-

*Translated for the Medical and Surgical Reporter.

koff, in *Centralb. f. gynak.* Of 243 women admitted there were seven pregnant; of these seven, four between three and four months, two in seven months and one in nine months. Tipjakoff was not satisfied that the fœtus died from the cholera poison but that the increasing prostration of the mother in the arrest of the interchanges of gases and the hæmorrhages between the uterus and placenta are sufficient themselves to destroy the life of the child.

Notes from the International Physiological Congress held at Luttich, 29, 30, and 31 of August, 1892: Wertheimer, of Nancy, made some experiments, according to Schiff, by injecting bile into the blood. The separation of these fluids increased the field of his studies. The question arose whether the injected products enter the liver or if they produce a more active secretion of the liver cells. Wertheimer used the bile of the sheep which has a spectrum of four characteristic stripes, while the bile of the dog as gathered from a biliary fistula shows no spectrum. When an injection is made into the vein of a dog of several c. c. of sheep's gall, one can find after fifteen minutes, the spectrum of the four characteristic stripes of sheep's gall in the fluid passing from the biliary fistula in the dog. When the injection is made into the mesenteric vein the immediate passage of the bile into the liver is proved.

The cerebro-visual centers in the dog and ape: Vitzou ablated the posterior portion of the left hemisphere corresponding to the lobus occipitalis of other mammalia until he reached the neighborhood of the cerebellum. He placed a bandage around the left eye of the dog, and observed that the animal could see but little through the uncovered eye; if he held a piece of meat near the three inner quarters of the uncovered eye the dog was unable to see the meat; as soon, however, as he placed it at the outer portion of the visual center the dog saw it. If the right eye is covered and you bring the meat near the outer quarters of the uncovered left eye the dog remains indifferent, if it however is brought near the inner quarters of the same eye the dog sees it at once. There is then homogeneous hemianopsie and an incomplete crossing of the nerve filaments in the chiasma. If the same operation is repeated on the remaining occipital lobe the animal becomes totally blind. The conclusions from this are that the removal of the occipital lobes results in a loss of visual perception. This opposes the results of the experiments of Goltz who claimed that a dog deprived of his brain lived eighteen months giving no signs of blindness. Ferrier and Yeo have placed the center of visual perception in the gyrus angularis. Vitzou has removed the gyrus angularis on both sides and was unable to produce blindness.

Total ablation of an entire hemisphere of the brain of the dog: Vitzou removed in April the entire left hemisphere of a dog three and a half months old. It was noticed on the following day that when the dog stood upright the limbs of the right side were relaxed and wanting in tone. In walking it was observed that the animal touched the floor with the outer portion of the right extremities and had a tendency to turn itself from right to left. About ten days after complete recovery, the dog was lively, but it was noticed the right extremities could be used less than the left.

Subcutaneous transplantation of the pancreas: Hidon, from Montpelier, was unable to successfully transplant the pancreas of the dog beneath the abdominal integument; it continued to act as seen by a small fistula through which the pancreatic juice exuded. This juice digested albumen, emulsified fats and contained sugar. In connection with the theory of diabetes of pancreatic origin he has made the following deductions. First, if the pancreas has been transplanted in a dog in which the intra-abdominal portions have been carefully extirpated there will be no glycosuria no matter how long the dog is under observation. Second, if the transplanted pancreas is extirpated glycosuria will at once appear. Third, if the transplanted pancreas begins to atrophy glycosuria will appear at once and increase in proportion to the progression of the atrophy.

Courmont and Dyon, of Lyons, interested themselves with the question—does Tetanus poison act upon the muscle or

nerve? They injected some of the poison into a frog. After the muscles became rigid they injected curare, after which the muscles relaxed. This led them to conclude it was no muscle poison. The authors in addition, to prove their theory, severed the main nerve supply of one hind leg of a frog and there injected the Tetanus poison. The enervated foot remained relaxed. The animal lived several weeks. This experiment again showed that Tetanus poison was not a muscle poison.—*Deutsche Med. Zeitung, 1892.*

Dr. L. E. Keegan (*Provincial Medical Journal*) speaks of the satisfactory action of boric acid in Typhus. He has used the remedy in fifty-two cases in doses of 0.6 to 1.2 grammes every four hours. Meteorism and diarrhœa at once become reduced and disappear, the tongue becomes moist and the general condition improves. In two cases Keegan believes to have shortened the attack by this medication. In the *Mèdicine Moderne* this method of treatment has also been recommended and 3.6 grammes of boric acid have been dissolved in a half litre of water and taken in divided doses in twenty-four hours. Dujardin-Beaumetz recommends a mixture of boric acid with other antiseptics. Borac acid, salol, beta naphthol, salic. of bismuth, each 0.25; M. ft. pulv. no. 12. S. One powder four times daily. The condition of the kidneys must be carefully watched and the urine examined daily for albumen.

Gibert has collected the statistics of 1000 infants who had been raised on the bottle and 500 which have been nursed at the breast. Of the 500 only two suffered from the disorder of dentition. Of the 1000, fifty-eight suffered from stomatitis, twenty-eight of Fraisen and he concludes from this that teething in children is aided through the normal physiological use of the gums at the mother's breast.—*Medicin Neuigk.*

Foucaut and Béranger-Féraud recommend the following drink for gout: Acid lact., aqua dest. ana 40.0; of this solution a teaspoonful each morning to three or four glasses of water sweetened if desirable and drunk during the day. At the end of twenty days an intermission is advised of ten or eleven days, to begin in same manner at end of that time. This is continued through many years. The above named authors believe they have seen a diminution in frequency and severity of the gouty attacks, and think there may be a possibility of their entire disappearance. The long continued use of lactic acid produces no deleterious effects on the digestive apparatus—*Medicin Neuigk.*

Tolerance of the abdominal cavity and uterus in pregnant women: In contradistinction to the small provocation for abortion in women in the higher grades of life, it is interesting to note the grave accidents to pregnant women living in the country notably through cow horns, which heal sometimes without interrupting the pregnancy. In 14 cases in which the uterus was torn, only 4 women died and this in the face of the fact that the tear was not sewed in any of them. Two children of the 4 dead mothers lived and 4 times mother and child lived. Even gun-shot wounds into the uterus, the ball remaining in the fœtus, have resulted in recovery after the fœtus was born; three cases of which were mentioned. A pregnant girl plunged a hat pin through the umbilicus into the abdominal cavity, aborted without further trouble than a short suppurating sinus near the navel.

Another case of recovery in a mentally diseased woman who had made a 4¾ incision in the median line through the abdomen and extracted the fœtus and killed it.—*Medicin Neuigk.*

ANTIPYRINE IN EPISTAXIS.

Dr. E. G. West, Boston, Mass., says that he has yet to find an agent so reliable in epistaxis or nose-bleed as antipyrine. It is his custom when a case of unusual violence occurs to saturate a pledget of cotton in a solution of antipyrine or in the dry powder and introduce it into the nostril. It stopped the bleeding in every instance that he applied it. The patient by this method is relieved of the disagreeable tarry clots formed by the solutions of iron so commonly used for this purpose, He finds antipyrine is an antiseptic that can be relied on, but he has learned to use it in smaller doses than formerly, and by so doing he can acquire the same results.—*Ex.*

Abstracts.

DIPHTHERIA.*

By A. BOWEN, M. D.,
NEBRASKA CITY, NEB.

Eleven years since, at the request of this Society, I addressed you upon this subject; and if to-day, at the request of your "Chairman of Committee on Practice of Medicine," I come before you and say that I have no new suggestion to make on treatment, you may think that I lack the spirit of progressiveness and that the light which science sheds over all things had not visited my eyes. The revelations of nature are old, and the powers of drugs remain the same to us that they did to our fathers. The same treatment with which I used to abort tonsilitis forty years since in the Catskill mountains, is all-sufficient, and ever has been, in extinguishing diphtheria, if the patients are seen early and treated from the first with *over-bearing and persistent earnestness.* Nothing less than this will answer and this always will.

I am not blind to the fact that different epidemics of diphtheria, like different epidemics of small-pox and scarlatina, possess different degrees of malignity, and will claim their victims; but I do know that all of you who are *terribly in earnest* can limit the mortality to less than five per cent. I do know—*I do not conjecture*—that German children are more obnoxious to the disease than American children; probably this is due to their different mode of living. Three years since, I was called to two families of Germans, eighteen miles from my residence. Seven members who were children in one family and four in the other. They had contracted the disease from the contagion of a corpse at a funeral. One in each family had had the disease for several days before I was called. I said to the parents that these two would die. Knowing that my word was law in those two houses, I unhesitatingly commenced the same course of treatment through the day among the sick and the well; among them was one baby who nursed a bottle. Their throats were earnestly swabbed every two hours during the day; and the sick during both day and the night. As fast as they came down with the disease I swabbed during the night as well as during the day. Every child had the disease and every child (except the one referred to above) in each family recovered. These two are the last children I have lost of diphtheria.

When epidemic commenced last November the Chairman of the Board of Education wrote to all the medical men in town requesting their opinion of the necessity of closing the public schools; all but one dissuaded them from closing. It was the mildest and the widest spread epidemic of diphtheria I ever saw. Still, there is enough diphtheria in every case, to kill, if neglected. I always grow poor in flesh when treating diphtheria. A a gargle for children who are exposed to contagion or infection, a four per cent. solution of carbolic acid, thoroughly mixed with cold strained tea, either gargled, or better yet, mopped deep in the throat every four hours; or if the disease has invaded the nostrils, or nares, or if it is threatening them, the same wash sent through a two or three drachm glass syringe with a somewhat forcible jet; a small cork being fitted to the nostril of the child with an aperture through the cork to fit the nozzle of the syringe and the child always held perpendicular. If the disease has invaded the throat, (as it usually has), then more earnest means must be used there; of twelve parts by measure,

One part is to be carbolic acid.
Three parts are to be sulphurous acid.
Four parts are to be glycerine.
Four parts are to be mur. tincture of iron.

The throat to be swabbed or mopped deep with this solution every two, three or four hours. They must eat and they must sleep, and here comes in the tact and discretion of a good nurse, and all you possess of these qualities you will find available. Intubation is a more respectable apology than laryngotomy, but the latter is merely a bloody excuse for early neglect. *Arrest* the disease at the earliest moment and save from its terrible alternatives—asphyxia or septicæmia. If your patient resists you, swathe him or her tightly from the chin to the toes, and get the mouth open by the help of a soft pine wedge; they will not resist you if their throats have been properly educated.

As to the cause of diphtheria we do not

*Read before the Nebraska State Medical

possess much more accurate information than we do of the cause of small pox, or scarlatina, or the epizootic. We hear that the latter disease has struck our Eastern coast and we know that in about so many days it will show itself in our stables, though the wind may blow a gale from the west all the intervening time. Diphtheria is surely "a pestilence that walketh in darkness." Belknap says in his history of New Hampshire that a visitation of what was probably (from the description) diphtheria first visited our country in 1735. Of the first forty who were attacked, none recovered.

In the parish of Hampton Falls, twenty-seven persons died in five families and one-sixth of the population died in thirteen months, and twenty families buried all their children. We may have reason to fear (for we have seen a similar error committed in our day) that some physicians may have depleted for the wretched fever which accompanies the disease, forgetting that it is adynamic in its character. Belknap says of the Boston visitation at this period, "The physicians having by desire of the selectmen held a consultation, published their opinion that it proceeded entirely from some *occult quality in the air*." Can their successors of the fourth generation give a more definite answer with assurance? And at what earlier day did an American town institute *scientific inquiries* as the basis of sanitary measures? I cannot look upon diphtheria, even in our present ignorance of its prime cause as one of the opprobria medicorum, but as a disease to be met earnestly and in a hopeful mood.

ON CERTAIN DIURETIC DRUGS.

Speaking of dropsy, Dr. Haig (*Lancet*, July 9th) says: All drugs that hinder the solubility of uric acid and clear it out of the blood relax the arterioles and cause diuresis, and indeed not a few drugs whose diuretic action is well known owe their property entirely to their action on uric acid and so indirectly on the arterioles. Thus opium, mercury, iodide of potassium and other iodides, salicylate of soda, caffeine and lithia salts, all produce more or less diuresis and diaphoresis, and all have this also in common—that they clear the blood of uric acid. Opium is often used, either alone or in combination, for its diuretic or diaphoretic properties. I have shown that it raises the acidity, diminishes the excretion of uric acid, and clears the blood of it. A good deal has been written about the diuresis produced by mercury and I have shown that it forms an insoluble compound with uric acid, clears it out of the blood and relaxes the arterioles. Iodides also are fairly well known as diuretics, and my researches show that at the time they cause diuresis they diminish the excretion of uric acid and clear it out of the blood, thus allowing the arterioles to relax. Further, the uric acid thus held back passes through the blood when the drug is let off, causing contracted arterioles, headache and scanty urine; in fact, a rebound, just such as is met with after opium, mercury, iron, lead, lithia, or any other members of this group. A good deal also has been written about the diuresis produced by salicylate of soda, but its effects in this direction are entirely dependent on the fact that it clears the blood of uric acid. Unlike the drugs I have already mentioned, it clears the blood of uric acid, not by rendering it insoluble and retaining it, but by rendering it soluble and producing its elimination by the kidney, and a knowledge of this fact gives us the explanation of an important point in which the diuresis produced by a salicylate differs from that produced by the before-mentioned drugs. Take a dose of opium, mercury or an iodide, the diuresis they produce comes quickly, within a few hours of swallowing the dose—*i. e.*, they quickly clear the blood of uric acid and relax the arterioles; but with a dose of salicylate this is not so. Take fifteen grains of salicylate of soda three or four times in one day, the urine will not be at all profuse; on the contrary, it will be rather scanty. Continue the same dose next day and towards the end of the second twenty-four hours there may be a marked diuresis.

Now, the explanation of this is simple. On the first day of its action the salicylate meets with a large amount of uric acid and passes a great deal of it through the blood and out by the kidney. The arterioles are consequently contracted and there is no diuresis. On the second day, however, the immediately available supplies of urate run short and excretion falls down almost to the level of formation. There is but little urate in the blood, the arterioles can relax and diuresis results. If a

patient has a large amount of urate in store the diuresis with salicylates may not occur till the third day, but in my own case it comes almost invariably about the end of the first thirty-six hours. It is evident, then, that the diuresis produced by a salicylate is not due to its direct action on the arterioles, but to its direct action on the amount of urate contained in the blood, and varies in accordance with the amount of this substance that it meets with. Precisely the same thing holds with the alkalies, soda and potash. Caffeine is well known to cause diuresis. I have pointed out that it diminishes the excretion of urates and relaxes the arterioles, and is well known to be useful in conditions of migraine and depression, no doubt from its action on the urates in the blood. Salts of lithia, again, produce a marked diuresis and this diuresis comes quickly, resembling that produced by opium, mercury and the iodides and differing from that produced by salicylates. But lithia salts act as alkalies, increasing the alkalinity of the blood and diminishing the acidity of the urine, and we have just seen that the alkalies (soda and potash) increase the secretion of urates and diminish the urinary water. Here again, as in the case of salicylates, we have the most absolute proof that the scanty urine or diuresis produced by drugs is due not to their action on the vessels, but solely to their influence on the solubility and excretion of urates, which have a powerful influence on the vessels. What is the action of lithia salts on the excretion of uric acid? They greatly diminish the excretion of uric acid, clearing it out of the blood and relaxing the arterioles; hence they produce diuresis. Soda and potash increase the uric acid and diminish the water.

EXCORIATIONS IN INFANTS.

Dr. Floyd M. Crandall, in an interesting article on the management of the newborn infant, states that he has obtained better results from an oily preparation than from powders, where excoriations are severe. He recommends the following, proposed by Fox:

℞

Acid Salicylici	gr. x.
Bismuthi subnit.	ʒ ii.
Amyli	ʒ iss.
Ung. aq. rosa ad.	ʒ i.

—*N. Y. Med. Jour.*

THE CARE OF THE NASAL PASSAGES DURING CHILDHOOD.

Dr. W. F. Strangways, in an article in *Physician and Surgeon*, calls attention to the care and treatment of diseases of the nasal passages, during early childhood. While great results are being achieved by preventative medicines, there are some fields sadly neglected, one of which is nasal affections and acute colds.

Between the months of November and May, every general practitioner sees many children suffering from cold in the head, little or no attention is paid to it. He regards it as a law, that every cold has a tendency to leave some chronic inflammation, which if kept up, will develop some form of rhinitis.

A large part of the catarrhal troubles of adult life, are directly traceable to the carelessness of both parents and physician, who allow colds in the head to pass by untreated in early life of the patient.

The first step, toward curing catarrhal troubles, in the nasal passages is to gain good vigorous health. Constitutional treatment is of great importance, cold baths, short exposure to cold air, frequent frictions and wearing woolen clothing are measures of first importance. Special attention should also be given to the child's feet. The medicinal treatment should require care and thought. Every physician has his own method of managing a cold: during the first stages, the general rule seems to be, to let it alone. So doing, they allow chronic rhinitis to develop. He recommends warm alkaline solutions, and medicines to restore heat and sweating, during the first stages Bicarbonate of soda and biborate of soda, thirty grains of each, in one pint of hot water, likewise solution of boric acid, are good during first stages. The main thing is to keep the nasal passages clear and prevent the discharge from being retained. For infants, the best way to use a detergent is to pour it into the nostrils, with a teaspoon; the medicament should be warm, mild, and only a few drops used at a time. An atomizer may be used with older children. Parents should be taught to look for, and remove any hard crusts which may form, and if the child is subject to repeated colds, it should have a careful rhinoscopic examination followed by proper treatment.

REPORT OF CASE OF IMPACTED CERUMEN AND ITS RESULTS.

Mr. B., aged 22; Seigel St., Brooklyn, came to my clinic at the Central Throat Hospital and Polyclinic Dispensary of Brooklyn for the treatment of a slight conjunctivitis.

I noticed that the patient was extremely emaciated and pale, seemed very weak and had frequent spells of coughing. Upon inquiry I ascertained that the patient had been under the treatment of various physicians and that almost all had given a diagnosis of "Incipient Tuberculosis." I learned that the patient had daily rise of temperature, night sweats and frequent spells of coughing followed by some expectoration. He had had one slight hæmorrhage and complained of pain in the lower part of thorax.

The patient having noticed me treating several ear cases, remarked that one of his ears troubled him and that he would like to have it examined. I found his hearing for the watch in right ear normal but in left ear only by contact. The tuning fork was heard best in front of right ear, but in the left it was heard only on application to the mastoid. When placed on the teeth or frontal bone the sound was positively referred to the left ear. This, of course, proved that there existed some occlusion of the auditory canal or a disease of the middle ear. Upon introducing an ear speculum I found a dense black mass of impacted cerumen, and it was one of the densest and hardest masses of cerumen I had ever been called upon to extract and I only succeeded after repeated syringing with a Pomeroy syringe and warm water.

After removal of the cerumen I found the tympanum thickened and very red and without the brilliant polish usual to that membrane and no light spot. The patient could now hear the watch at a distance of three inches.

I introduced a small piece of borated cotton in the auricular canal to exclude the cold air, from this, but lately covered drum, and directed the patient to call again. I did not see him again for two weeks, and on his return, I with difficulty recognized him. He said his cough had almost entirely ceased, that he had no more night sweats, no pain in the thorax, slept well, temperature normal and, as he declared, had a most glorious appetite. He had gained about ten pounds in weight. This most unexpected change in the patient's condition, of course, interested me greatly and as I found that he still expectorated slightly I secured some of the sputa and had it examined for tubercular bacilli. The results of the examination were negative.

I saw the patient four weeks afterward and he had rapidly gained flesh, his cough had entirely ceased and all other general symptoms had disappeared. He said he felt entirely well and was soon to go to work. Upon examination the ear showed an almost healthy drum membrane slightly sunken. The light spot had returned but slightly out of position and diminished in size. Hearing for watch in this ear was good at four feet.

The pressure and irritation of the impacted cerumen upon the tympanum causing reflex cough had evidently given rise to the patient's general symptoms. The incessant coughing caused a laryngitis and bronchitis, and to them were due the rise of temperature and general debility; and the great strain upon the diaphragm and thoracic muscles, accounted for the thoracic pain.

This was in the months of February and March. I saw the patient the last time on the second of July and he appeared in perfect health and weighed about 155 or 160 pounds. When I first saw him he only weighed at the best 105 pounds.

Although these cases are exceedingly rare, there being only one or two on record, yet this one case, showing such a fearful result from such an obscure cause, and one which, as shown in this case, is so readily overlooked, may prove of some interest and value to the general profession. —*Miss. Med. Monthly.*

TREATMENT OF VOMITING OF PREGNANCY.

Routh states that in seven years' practice he has always been able to arrest the vomiting of pregnancy by brushing the cervix and lower cervical canal with a mixture of equal parts of iodine, iodide of potassium, spirits of wine and water.

In general the vomiting ceases immediately after the application. If the vomiting should recur, the cervix should again be brushed. Generally after this the vomiting will be permanently relieved.—*Therap. Gazette.*

Selected Formulæ.

COD LIVER OIL EMULSION.

℞
Cod liver oil.....8 fl. oz.
Yolks of eggs.....2.
Tragacanth in powder.....16 grains.
Tincture of benzoin.....1 fl. dram.
Spirit of chloroform.....4 fl. drams.
Essential oil bitter almond.....8 minims.
Water to make.....16 fl. oz.

Sig.—Rub the tragacanth with a small quantity of the oil, then add the egg, and with constant trituration water and oil alternately and the flavoring ingredients until the emulsion is completed. About two fluid ounces of water will be needed.

—*Br. and Col. Druggist.*

DIPSOMANIA.

Alexander gives the following as a good remedy to enable drunkards to resist the drink crave:

℞
Tinct. capsici.....M x.
Sodii bromidi.....gr. x.
Spirits ammoniæ.....℥ i.

Sig.—Give at a dose several times daily.

—*N. Y. Med. Jour.*

ANTISEPTIC POWDER, IMPROVED.

Cheap but reliable substitutes for these expensive proprietary preparations, as well as for iodoform, however, are always in demand. The following formula is used largely in the hospital wards of a city institution in the treatment of chronic ulcers, suppurating sores, and generally as an iodoform substitute:

℞
Salol, powdered.....℥j.
Sulphite of zinc, powered.....℥iss.
Benzoin, powdered.....℥ss.
Purified talcum.....℥ij.
Oil of fennel.....M xx.

M. et. sig.

—*American Druggist.*

CHRONIC DIARRHŒA WITH INTESTINAL FERMENTATION.

℞
Salol.....3 parts.
Castor oil.....15 "
Rhubarb.....30 "
Gum arabic.....10 "
Water.....120 "

Mix. A tablespoonful every hour till the bowels move.

—*Le Prog. Med.*

GONORRHŒAL ERECTIONS.

PILLS.

℞
Camphor.....2 grammes.
Opium extract.....0.2 gramme.

For 20 pills; 4 pills to be taken at night—1 every 15 minutes.

—*Jour. des Mal. Cut. et Syp.*

CHRONIC RHINITIS.

In the remedial treatment, the following has proven of service, used with the atomizer twice or thrice daily. If used as a douche, dilute with two or three parts water. Note: The iodine is decolorized in preparation, a clear solution of light amber color resulting.

℞
Sodii boras.....½ drachm.
Sodii bicarb.....1 drachm.
Aquæ puræ.....2 ounces.

Dissolve and add

Acid carbol.....15 grains.
Tinct. iodi.....3 drachms.
Listerine.....q. s ft..4 ounces.

Mix.

—*Med. Brief.*

The following may be given with benefit to allay the craving for alcohol, and to some extent take its place:

℞
Spt. ammon. aromat.....℥ii.
Tinct cinchonæ.....℥iiss.
Tinct. capsici.....℥iii.

Sig. A large teaspoonful in half a tumblerful of effervescing potash water every hour.

—*Whitla's Dictionary of Treatment.*

ANTISEPTIC MOUTH WASH.

Muller advises:

℞
Acid thymic.....gr. iv.
Acid benzoic.....ʒ ii.
Tinct. eucalypti.....℥ ss.
Spt. vini. rect.....℥ iii.
Ess. menth. pip.....gtt. x.

Sig.—Drop enough into a glass of water to cause turbidity, and rinse the mouth morning and night.

—*Med. Rec.*

THE PREVENTION OF OPHTHALMIA NEONATORUM.

The New York Legislature passed the following act, to take effect on the first day of September, 1890: Sec. 1. Should any midwife or nurse having charge of an infant in this state notice that one or both eyes of such infant are reddened or inflamed at any time within two weeks after its birth, it shall be the duty of such midwife or nurse having charge of such infant, to report the fact in writing within six hours to the health officer or some equally qualified practitioner of medicine of the city, town or district in which the parents of the child reside. Sec. 2. Any failure to comply with the provisions of this act shall be punished by a fine not exceeding one hundred dollars, or imprisonment not exceeding six months, or both. If the provisions of this act are enforced a very marked reduction of the blind will result.—*Boston Medical and Surgical Journal.*

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY, NOVEMBER 12TH, 1892.

THE PRACTICAL VIEW OF ECTOPIC PREGNANCY.

Theory and practice go hand in hand in the general application of medicine and surgery in the ordinary routine of the physician only so far as is best for the ultimate good of the patient. This is another way of saying that if theory cannot promise better results than tried and therefore applied therapeutics or surgery, these latter are to have the preference, and the problematical remedy is to be left for a less urgent occasion where no life is involved. For the every-day practitioner, and for him especially who is alone, and must rest his case on his own ability to rise equal to any emergency, and where the possibility of so doing depends entirely on his previous experience, reading, and natural bent, the question of speedy resort to surgical interference in ectopic gestation where the symptoms are urgent, is always a matter for grave consideration. This grave accident in the childbearing woman, may from its incipiency be ever on the verge of disastrous rupture, and on the other hand may rupture without accident, and the fœtus die or go on to full term. With these facts before him what is the obstetrician in general practice to do. It is easy enough in a large medical centre like Philadelphia, where a score of men ready to operate are always at hand, to make a speedy resort to surgery, without delay, with a fair chance of saving the patient. It is first imperative to understand what the common symptoms of ectopic gestation are, in order to be on the lookout for it. In the first place it is to be thought of in conception after long sterility; it is to be kept in mind in sudden accident in those who are illegitimately pregnant. It is to be considered as a possible contingency in those women who have a longstanding pelvic inflammation with a more or less extended period of sterility. The pathology of these conditions as related to the condition of pregnancy will not be here discussed. Sudden attacks of pain in pregnancy after or in any of these conditions, ought to be regarded with concern. Examination carefully made, after the occurrence of pain, may reveal the presence of an unatural swelling in relation with the uterus, and if along with this, there are present symptoms of pregnancy, the patient ought to be dealt with as a suspect, and her condition determined, by careful consultation. This early done will give her the benefit of any doubt, will antedate probably any dangerous period in pelvic inflammatory disease apart from ectopic, and anticipate all complications arising therefrom. This rule will apply in the non-fulminant ruptures of the ectopic sac. In these latter there is no time left in which to seek consultation. The woman is found in collapse, pulseless,

and suffering excruciating pain, or with a history of it.

There is no time left for delay. The delay that falters is the same that kills, and speedy aid must be afforded. To have success in these cases must not be considered certain by the casual operator. We read too often that the cases when operated on are sure of recovery. This means in surgical hands, in clean hands, in expert hands, that can open the abdomen, tie off the bleeding vessels, wash out the masses of clot and debris, without delaying to be clean, or to get clean, or to stop and wonder along the road of operation.

Unless a man can do all this, his patient has about as good a chance of getting well without surgical interference as with it, and this is saying very little.

The surgery that gives success equally in all hands has not yet been discovered. Good result and bad will always be had in every department of the art where the skill is variable. The safeguard of every community, no matter how situated, is to see to it that it has and encourages some man by its support to devote himself sufficiently to such study and investigation as will enable him to rise equal to an emergency of this order with good hope of success. To know the best and speediest way of controlling the hæmorrhage of ectopic gestation is one thing; successfully to accomplish this is another, so far as after-results are concerned.

The main point is, in this as in all other delicate surgery of the abdomen, to know how to be clean. To be clean physically, not to trust to chemicals. The man who is dirty till he is disinfected with sulphur, chlorine and carbolic acid, will be essentially dirty after he is through with all these. Like seeks like, and if he is not by habit clean he will do a dirty operation. In all obstetric and gynecological surgery the road to success lies by the way of clean body, clean clothes, clean instruments, clean beds, and clean patients and nurses. The man who has not these, and is not all of this, in his ideas and requirements, has only luck if his results are good, and his desserts if they are bad.

A MIGHTY BAD RISK.

He was a man well along in middle age and was willing to be insured. The agent had prepared his "application," and turned him over to the searching scrutiny of the accomplished medical examiner. "I might as well tell you, doctor, to begin with, that ours has been a family of fatalities and sudden death," said the applicant. The examiner looked serious as he replied: "Why, you seem to be in excellent physical condition. What did your father die of?" "Heart disease." "That's bad. How old was he?" "Ninety-two." "Um! And your mother?" "She's gone too. Killed at a crossing." "And her age?" "Mother was a little over 79." "Do you know the age, and cause of your grandfathers' deaths?" continued the examiner. "Yes, indeed. Father's father died just a week after his 90th birthday. They say he used too much tobacco. Mother's father was only 88. Falling down stairs finished him." "And your grandmothers?" "One of 'm had consumption at 86, and died of it in no time. The other was nipped by a sunstroke at 84. Oh! they all went quick." The examiner did not seem so grave as he asked: "Have you any brothers or sisters?" "One sister and two brothers," was the answer. "John went out into the mining country when he was 72, got into trouble there, called a drunken man a liar, and was shot. Henry was drowned at 69, trying to help save two young fellows that couldn't swim. Sister's alive. She's awfully careless; eat a lot of green stuff the day of her golden wedding, then danced in the evening with all the old fellows on the lawn, even after it was raining; took her two days to get over it. She'll go in a hurry like the rest some of these times.'

"Well," said the medical gentlem smiling, "Think I'll chance you, and don't believe your application will be 'turned down' at home office. Only you must look out for yourself. Be careful about catching hard colds after you are 80 years old."—*Chicago Post.*

Book Reviews.

A Manual of Medical Jurisprudence and Toxicology, by Henry C. Chapman, M. D., Professor of Institute of Medicine and Medical Jurisprudence, in the Jefferson Medical College, Philadelphia, with thirty-six illustrations. W. B. Saunders, 913 Walnut Street, Philadelphia, Pa. Price $1.25 net.

It is very necessary that every physician should have some knowledge of Medical Jurisprudence. The physician should know what the commonwealth expects and demands of him in his professional capacity, as well as to know his own rights as a medical expert. The author has written a plain, concise work, setting forth the leading facts, without going into lengthy discussions. We recommend the book to any one desiring more knowledge on Forensic Medicine.

Disease of the Kidney and Bladder, A Text-Book for Students of Medicine, by W. F. McNutt, M. D. etc., Professor of the Principles and Practice of Medicine, University of California. J. B. Lippincott Co., Philadelphia, Pa. Price $2.50.

This work is based upon a series of lectures delivered in the University of California. The nomenclature of kidney diseases is considerably simplified, especially of the inflammatory varieties.

A commendable feature of the work is the part devoted to the anatomy and physiology of the kidneys. The author very rightly says, a thorough knowledge of the anatomy, physiology and histology of the kidney is indispensable to the proper understanding of the etiology and symptoms of its pathological conditions.

BLACK EYE.

There is nothing to compare with a tincture or a strong infusion of capsicum annuum, mixed with an equal bulk of mucilage or gum arabic, and with the addition of a few drops of glycerine. This should be painted all over the bruised surface with a camel's hair pencil, and allowed to dry on, a second or third coating being applied as soon as the first is dry. If done as soon as the injury is inflicted, the treatment will invariably prevent the blackening of the bruised tissue. The same remedy has no equal in rheumatic, sore or stiff neck.—*Medical Times.*

Correspondence.

QUACKS.

Editor of MED. AND SURG. REPORTER.—In the last few months I have quite frequently happened to pass or to wait near an old Indian doctor who stands leaning against one of the stalls in a public market. His clothes are dilapidated and his dark face is shaded by a well worn broad-rimmed, chip hat. The only thing about him that would suggest his vocation is a black leather case, containing a number of small vials and a package of carefully cherished printed sheets, announcing the virtues of his vegetable remedies. Two or three times I have seen some one stop and ask him questions about his medicine, but as yet I have failed to see a sale accomplished.

Within half a mile of this camp-follower of our profession are two or three other doctors, occupying commodious and comfortable buildings, employing a staff of physicians and a corps of clerks and servants to flood the country with literature (pardon the word) announcing to the people at large, that the medical men of that particular institution have, in some manner not very clearly explained, gained a better knowledge of disease and a greater skill in its cure than ordinary physicians and surgeons who have yet to learn the value of a proper combination of paper and printers' ink. The men in charge of these institutions are well-dressed and prosperous; they and their assistants are graduates of medical colleges, and conform to the letter of the laws regulating medical practice. By the laity they are looked upon as desirable citizens, their social status is good and they may even take an active part in church work.

Here are the extreme phases of irregular practice, the one such as to excite our ridicule and pity, the other holding out, with the apparent frankness of methods customary and legitimate in ordinary business, the hope of speedy and certain cure and by a combination of some degree of medical knowledge, of fraudulent generalizations as to its abilities, and a shrewd commercial spirit, this caricature of our profession has established itself too firmly to call forth an expression of mirth. There is a short, crisp word which we could apply with impunity to the Indian

doctor, but it would be a dangerous, perhaps a costly experiment to name by this word any of the better clothed and better housed advertising physicians. Any difference of opinion between the regular medical profession and other bodies of medical men ought to involve no condemnation nor hostility as long as those differences are held in good faith and do not apply to matters of integrity and decency of conduct; but if possible, there should be such a definition of the word *Quack* adopted by the medical profession that that word could be used when occasion requires with fixed meaning and without the risk of legal procedures. A physician's legitimacy depends upon two factors, first that he shall have been properly prepared for his work, secondly that he shall carry on his practice in a becoming manner. In the writer's opinion any one who departs seriously from either of these requisites should be denominated a quack. To be more explicit, the following definition is offered:

1. A quack is a person practicing medicine without having graduated from a genuine medical college (except a medical student practicing for the sake of experience or any one rendering temporary relief as a matter of charity.)

2. A quack is a person, whether regularly graduated or not, who advertises his medical qualifications in public prints, circulars or by any other means except the sign and office card employed in the manner established by custom. This statement should not be construed as offering any objection to a physician's becoming well-known socially or in any non-medical way unless his social, scientific or other pursuits are mere subterfuges to enable him to advertise himself as a doctor.

3. Qui quackit per alium quackit per se.

It is becoming altogether too frequent an occurrence that physicians connect themselves with some advertising institution (no allusion is intended to properly conducted and properly advertised hospitals and sanitaria) expecting ultimately to join the ranks of the regular profession which is quite too lenient with its pardon for these who are ready to abandon their sins against medical ethics and be received into the membership of a county society. Without exceptionally favorable opportunities, it requires considerable hardship and self-denial for a man to establish himself as a physician and it is by no means encouraging to one striving to be decent and "ethical" in the midst of such trials to see some one else take the easy but disreputable road around the difficulties of the first few years of medical practice and reach the same goal toward which he is himself struggling. Better failure than such success, for of the fifteen or twenty per cent. of medical graduates who abandon practice, more do so from lack of persistence or on account of better inducements in other fields of labor than from lack of ability.

I have known men to teach school, operate telegraph instruments, sell books, represent wholesale pharmacists, work in drug stores, manage Turkish baths, practice stenography, cut hair, sell tin-ware, wait at hotel tables, because they were not in circumstances to begin the practice of medicine for which they were prepared. For all these men I have had a wholesome respect. On the other hand, men better qualified intellectually than the majority of those referred to, men who previously supported themselves in other ways, have deliberately gone into advertising medical institutions, either with the intention of following such a life or as a make-shift till an opportunity for embarking in regular practice should present itself. A physician,* speaking with reference to the ingratitude of these men to their alma mater compared them to "foul birds which soil the nest in which they have been reared."

The writer has no personal motive in pronouncing an invective against this particular form of irregular practice nor does he consider it as a graver evil than those species of quackery whose symptoms are more striking. He simply wishes to call attention to it as an evil which has insidiously fastened itself upon the medical profession and of whose importance few are cognizant.

THERAPEUTICS.

THE TREATMENT OF SKIN DISEASES.

At the meeting of the American Dermatological Association, recently held in New London, Conn., Dr. Condict W. Cutler, of this city, read a very interesting paper on the treatment of certain skin diseases by the use of an irritant application composed of iodine, carbolic acid and chloral, in equal parts. He stated that perhaps in no branch of medicine has greater advancement been made than in dermatology, so far as the pathology and diagnosis are concerned, but that in the treatment of skin diseases, especially in the chronic forms, very little improvement is found. The trouble is that we are too apt to use bland and soothing applications, and the remark once made by a distinguished dermatologist that the "basis of all treatment of skin diseases is grease" still is true.

A slight, stinging pain is first produced, which is soon followed by a decided numbness of the skin over which the solution is painted. This solution possesses strong antiseptic, antiparasitic, antipruritic, antiphlogistic, analgistic, anæsthesic and absorption properties. It penetrates deeply into the tissues of the skin not only hastening the absorption of inflammatory products but being itself readily absorbed.

The chief therapeutical advantages of the mixture are due to its penetrating action into the tissues, its rapid destruction of all forms of micro-organisms, and its wonderful power in hastening the absorption of inflammatory products. He considers it especially serviceable in parasitic skin affections and in all forms of chronic skin diseases characterized by thickening and induration of the skin, accompanied by scaling and itching.—*Ex.*

DENTAL USES OF THYMOL.

In the *Deutsche Monatsschrift für Zahnheilkunde,* January and April issues for 1892, A. J. Hartmann calls attention to the value of thymol as a medicament in the treatment of acute pulpitis, claiming for it an antiseptic and germicidal action which is sufficient to arrest the inflammatory proeess resulting from microbic infection without exerting any escharotic effect upon the pulp-tissue. He cites cases of pulpitis with exposure successfully treated by thymol in substance, and recommends it as decidedly superior to carbolic acid as a preliminary treatment to the capping operation, which he asserts may be successfully performed after a sufficient treatment with thymol.

A limited series of experiments made with this drug fully substantiate the claims which Hartmann makes for it. The application may be made either by applying a small crystal or a powder of the pure drug directly to the pulp, and sealing it in under a suitable temporary stopping. A saturated solution of thymol in chloroform may be used on cotton, or the drug may be melted in a small capsule of metal or porcelain, and a pellet of cotton or small disk of blotting-paper dipped into the fluid thymol and applied. The drug possesses the peculiar property of remaining fluid long after its temperature has fallen below its fusing-point, which gives ample time to apply it to the pulp-exposure before solidification takes place. In every instance so far as tried, relief of pain instantly follows the application. In deep-seated caries with great sensitiveness of dentine where it is proposed to temporarily fill with gutta-percha, very satisfactory results have followed from touching the warmed and plastic gutta-percha to the surface of a thymol crystal, which slightly softens the surface of the gutta-percha by its solvent action, renders it adhesive as does chloroform or cajuput, and when inserted exerts an antiseptic and obtundent effect upon the dentine. Its use in this way suggests the possibility of its value as a component part of the gutta-percha temporary stopping material in the preliminary treatment of cavities with sensitive dentine.—Edward C. Kirk, in *Dental Cosmos.*

ALCOHOLISM AND ITS TREATMENT BY STRYCHNINE.

In a pamphlet recently published in Tena, G. Beldau discusses all the papers, hitherto published in Russia and France, on strychnine treatment of alcoholism. Of peculiar interest and importance are the animal experiments performed by S. W. Jaroschewski, which demonstrate that in dogs strychnine possesses the property of neutralizing the inebriating action of alcohol, and that dogs that are given

strychnine and alcohol at the same time, are under incomparably better vital conditions than dogs taking alcohol alone. The latter died spontaneously, without an exception, while the former (excepting one who died from strychnine poisoning) continued living.

The result of experiences in man is the following:

1. Strychnine is a physiologic antagonist of alcohol, and treatment of alcoholism by nitrate of strychnine gives more or less favorable results.

2. The best results are obtained in dipsomaniacs, less good results in chronic drinkers.

3. The higher the doses, and the longer the treatment is continued, the more satisfactory is the result. Luton administered grm. 0.005 subcutaneously, or grm. 0.03 internally, 3 times daily; Korona, grm. 0.005–0.01! once daily, and noticed gradual disappearance of the longing for alcohol after a few injections.

4. Alcoholics support disproportionately large doses of strychnine without secondary phenomena, without accumulative effects.

5. It appears that strychnine has the property of eliminating the craving for alcohol in the potatory.

The author engaged in experiments in the clinic of Tena abstains for the present from an expression of his own views on the value of the remedy, promising some early communications on the subject. — *Can. Lancet.*

SURGERY.

THE DIAGNOSIS OF HEAD INJURY FROM DRUNKENNESS.

Dr. L L. von Wedeking writing to the *Lancet* on this subject, makes the following interesting statement:

A cell, or even a police station, is not a good place to form a correct diagnosis, and the frequency with which one finds symptoms very much obscured by alcohol is well known to police surgeons. A method which I employed while engaged in a very active emergency service in New York City, and which to-day is in extensive use in this class of cases, answers every purpose desired, and is more easy of application and devoid of the danger attendant upon the inhalation of ammonia. By pressure upon the supraorbital notches, compressing the nerve, a diagnosis of alcoholism may with absolute certainty be made in a few seconds, thus differentiating on the spot between coma due to alcoholism, injury or disease. Where no result is obtained, one may, with almost positive certainty, look for some other cause of coma. In no case have I failed with this method, and so certain became I of its infallibility that, without waiting to further examine for head injury where no result was obtained, I took the patient to the hospital sure of a "case." A case of alcoholism pure and simple will, upon the application of this pressure, immediately show very evident signs of life, and, be the coma ever so deep, the effect of the alcohol will for a short time be sufficiently removed to permit a thorough and rapid examination. The absence of result from this method should at once cause great suspicion of some cerebral trouble due to injury or disease. I would add, that to quiet hysterical convulsions, in hiccough, in alcoholic mania and for the detection of malingerers, there is, to my mind, nothing superior.

HOW TO POULTICE THE EAR.

Poulticing an ear may seem to be a simple operation, but there is nevertheless a right and a wrong way of doing it, and it appears that the wrong way is the one usually adopted. At least, so says Dr. Alfred H. Buck, of New York, in an article on aural therapeutics in the March number of the new *International Medical Magazine.* Dr. Buck says that while heat is one of the best remedies in painful inflammations of the middle ear, and the poultice is one of the best methods of applying heat, as usually put on the poultice has little effect. What should be done, he says, is first to fill the external auditory canal with lukewarm water, the head resting on the unaffected side upon the pillow. Then a large flaxseed poultice is applied over the ear as hot as it can be borne. The column of water is thus kept warm and acts as a conductor of heat between the poultice and the inflamed surface.

EVILS OF CATGUT.

Some interesting experiments have been made by Klemm (*Bull. Gen. de Therapeut.*) in which was demonstrated from an aseptic standpoint the superiority of silk over catgut for suturing wounds. When

catgut is employed in surgery, suppuration occurs in spite of all precaution. This led Klemm to suppose that the catgut, itself sterile, afforded a favorable culture medium for the development of such germs as get into a wound during an operation. To ascertain the correctness of his views, he made a number of comparative experiments on cats and rabbits with silk and catgut, with results as above indicated. The gut, after being used, and then placed upon a gelatine culture medium, developed as many as 2,500 colonies, while silk, similarly treated, showed only seventy-five. He, therefore, concludes that catgut, notwithstanding the thorough method of sterilization, as employed by such men as Riverdin and Brunner, is unfit for employment in surgery.

MEDICINE.

TREATMENT OF VOMITING.

Dr. H. B. Lowry says (Kansas City *Med. Index*) that for vomiting, arising from various causes, but especially that of gastritis, pregnancy and phthisis, the remedy par excellence, the action of which, when all others have failed, is indeed most gratifying, is tincture of iodine, ten drops to be taken in water, in divided doses after meals. In the graver lesions of the stomach, such as dilatation, gastric ulcer, cancer, etc., there is much minutia in the treatment, as regards diet, drugs, their methods of administration, and the position the patient should assume under certain conditions, to which the conscientious practitioner must give due diligence. He also calls attention to the discussion that has been going on of late in regard to internal antisepsis, the opinion of the German physicians being that it is very doubtful whether antiseptics given by the mouth ever reach the intestine; they are probably absorbed in the stomach; however, calomel given with this view, where the trouble was not serious, has been thought to be beneficial. In several severe cases of dysentery in a London hospital, after utter failure with the use of opium, lead, ipecacuanha and bismuth, there was tried an enema of alum—half an ounce to the pint of water, twice daily, and in each instance complete recovery resulted. In one instance the disease had been of many years standing, but the result was equally gratifying.

THE DISEASES AND ACCIDENTS OF GREAT CROWDS.

The medical history of the great Columbian celebration, which produced so much enthusiasm in this city last week, deserves some attention, and if it could be completely written would prove most interesting. There were probably four hundred thousand or five hundred thousand visitors during the week and perhaps a quarter of a million persons crowded the streets along which the parades were held. It is estimated that two hundred persons were more or less hurt or taken ill. The census as gathered by newspaper reporters from the police reports and hospitals makes the number about one hundred. Our readers will be interested in the list, as showing the accidents and diseases of great crowds. It is as follows:

Fainting, 35; hysterical seizures, 3; epileptic fits, 11; sprains, 3; run over, 3; fractures, 10—1 of the arm, 2 of the skull, 7 of the legs; falls, 11; cramps, 1; dislocation, 1; burned, mortally, 1; struck by a brick, 1; "taken sick," 13. Total, 94.

This shows that fainting is the most frequent pathological phenomenon, that crowds are bad for epileptics, that falls and fractures are numerous, and that delicate people are liable to be "taken sick." On the whole, the record is not a bad one, considering the enormous congregation of people. The reports also show that the sick and injured were promptly and efficiently cared for and our much abused ambulance service evidently did yeoman's duty on the occasion.—*N. Y. Med. Rec.*

NEURALGIA OF THE TOE.

A neuralgic pain, more or less severe, at the base of the fourth toe is not uncommon, but has attracted medical attention only within recent years. Dr. Morton of Philadelphia, in 1876, was the first to describe it, and to report a number of cases. He had himself suffered a great deal from it.

The attacks always come on suddenly. He was often obliged to remove his boot, sometimes when walking in the street, sometines when riding in his carriage, and sometimes even when in company. When on horseback he has been compelled to dismount, tie his horse to a tree, and lie on the grass, unable to proceed further.

He found the affection much more fre-

quent in women than in men—a result, no doubt, of the greater delicacy of women's feet and of their wearing tight shoes.

Dr. Bradford, to whose paper on the subject, read before the Suffolk Medical Society, we are indebted for our facts, says that his own investigations in respect to this ailment accord exactly with those of Dr. Morton; that the symptoms were the same, and the proportion of male and female patients about the same.

One of Dr. Bradford's case was that of a young lady obliged to stand all day. She was in excellent health, but for years had suffered from pain in her right foot, radiating from the base of the fourth toe. Her shoes were made with great care, but she suffered all the time, and sometimes the pain was so intolerable that she would willingly have submitted to a surgical operation for relief. She was relieved by treatment and properly constructed shoes.

The following is, in brief, an explanation of this metatarsal neuralgia," or "Morton's affection of the foot." The base of the fifth, or little toe is in a line with the neck of the fourth toe's corresponding joint, and by becoming pressed against the nerves of the latter, it irritates and inflames them.

The pain which results is sometimes only of a dull character, but sometimes is severe and throbbing, and may extend above the ankle. As in other neuralgic pains, there is no inflammation to be seen nor any swelling.

In most cases protracted rest and the use of quite broad-soled shoes will effect a cure; but sometimes the excision of the head of the fourth metatarsal bone is necessary.—*American Analyst.*

TREATMENT OF DIPHTHERIA WITH ARSENITE OF COPPER.

Success in the treatment of diarrhœa and dysentery with arsenite of copper, at first recommended by Dr. Aulde, of Philadelphia, suggested the idea of its use in diphtheria, on the ground that it was the alimentary system that was involved in both cases. The first of October, 1891, an epidemic of modern severity made its appearance in this city, and lasted for several months. My cases, varying in age from one to ten years, were put upon the arsenite treatment, which was supplemented by small doses of calomel when it was needed on account of constipation. Inunction with sulphate of quinine suspended in glycerin was practised in all cases, usually repeated every four hours. How much quinine was absorbed I do not know, but the plan keeps the skin in good condition. Where there was much cough or hoarseness, equal parts of glycerin and any good wine were given with the arsenite, or, if that was not agreeable, one per cent. of benzoic acid, combined with powdered sugar, was dropped on the tongue and repeated as often as thought necessary. No local applications were made; the surroundings were looked after; and when (as happened in some of the cases) little food could be taken, an effort was made to induce them to take water freely, either plain or in the form of lemonade. None of these cases were malignant, none died, and none suffered from unpleasant sequelæ. Such a short experience in the treatment of such a disease ought not to count for much, but I feel certain that the plan will prove (to say the least) as successful as any, while its application will be more agreeable to all concerned.—*Indiana Medical Journal.*

OBSTETRICS.

THE PROPER METHOD OF APPLYING OBSTETRIC FORCEPS.

Dr. Henry D. Fry urges, as the only rational method, the application of the forceps to the sides of the head of the child without reference to its position in the pelvis. He refers to a former paper in which it was stated that fifty-one per cent. applied the blades in transverse diameter of the mother's pelvis without reference to the position of the head, and eleven per cent. observed no rule and followed either method. He admits that had the great body of the profession been consulted, the majority would be found to apply the forceps according to the German method, and also that in some cases it may be and is impossible to do otherwise. Certainly the difficulties of application are increased when the first method is chosen, and it would be better for a beginner to resort to the second until some facility is acquired. In France the practice to apply the forceps to the sides of the head even when transverse at the brim, and the ideal method of extraction is to apply the instruments in such a manner that during traction the

fetal head is free to execute all the movements that would occur were the labor normal. To accomplish this it is necessary: (1) To grasp the sides of the head with the blades. (2) To make traction in the axis of the pelvic canal. (4) To secure mobility of the head during its passage, by the use of Tarner forceps. The Hodge style of forceps should not be used when their application is made without reference to the child's head, and the Simpson style (Elliot) should not be used when their application is to be made to the side of the head. Dr. Fry's conclusionsa re: (1) Anæsthetize the patient and place her in proper position—buttocks well over the edge of the bed, and each limb supported by an assistant. (2) Ascertain the position of the head, introducing within the vagina two or three fingers, or if necessary, the whole hand. (3) Apply the blades of a Hodge type of forceps to the sides of the head, with the concave edge directed toward the occiput. If for any reason this cannot be accomplished, withdraw the instrument and substitute a Simpson (or Elliot) passing the blades to the side of the pelvis. While making traction with this method, watch for an terior rotation of the occiput, and encourage it in some cases by re-applying the blades to better advantage. (3) Make every effort to secure antiseptic condition during the operation. The fingers, hands and forearms of the operator, the external genitalia and vagina of the patient, the instruments and the hands of the assistants, should be clean and aseptic.—*Am. Jour. Obst.*

TREATMENT OF METRORRHAGIA.

In certain cases of obstinate metrorrhagia, ergotin, extractum hydrastis Canadensis, ice, and applications of tampons are alike incapable of arresting the hæmorrhage. In such cases a hypodermatic injection of sulphate of atropine has been recently recommended. It is given in doses of $\frac{1}{200}$ grain twice daily. In one case in which the hæmorrhage had existed for a fortnight, it was completely arrested after a fourth injection. In a second, when the patient was in a state of collapse, the first injection was followed by a return of the normal temperature and increase of the pulse-rate; after the second the hæmorrhage was diminished in a striking degree; after the third it entirely ceased. A moderate dilatation of the pupils was the only secondary effect observed.—*The Provincial Journal.*

HYGIENE.

SIMPLE TESTS FOR IMPURITIES IN WATER.

The following methods of determining the presencc of impurities in water are given by Walling: 1. For organic matter put a little of the sample into a beaker, add two or three drops of dilute sulphuric acid and color distinctly with a solution of permanganate of potassium. If much organic matter is present the color of permanganate becomes discharged almost immediately; if less or very little, it takes longer to decolorize. If the color has not changed in twenty-five or thirty minutes it is safe to assume that organic matter was not present. This is a tolerably reliable test. 2. For nitrites, a little sulphuric acid added to the water forms nitrous acid if nitrites are present, which is easily detected by its power of liberating iodine from iodide of potassium. A little starch paste is mixed with a small quantity of a solution of potassium iodide, and the mixture added to the suspected water containing the sulphuric acid. If nitrites are present the nitrous acid formed liberates the iodine from the iodide, which turns blue with starch. This indirect method is a ready means for detecting the nitrites if present in not too small a quantity. 3. Nitrates are detected by converting into nitric acid, which turns morphia red. A portion of water is evaporated to dryness, the residue treated with a drop of strong sulphuric acid (which makes nitric acid of the nitrate) and a portion of morphine added. If nitrate is present the morphine gives red color. 4. For ammonia, Nessler's reagent is by far the best test. It may be made by dissolving eighteen grains of oxide of potassium in a little water, adding solution of mercuric chloride until the red iodide of mercury first formed redissolves upon agitation. To this is added a solution of fifty grains caustic potassa and distilled water to make eight ounces. This reagent will detect 0.00375 of a grain in a pint of water by giving a yellow color. A

reddish color or precipitate forms with larger quantities of ammonia. 5. Albuminoid matter requires a more elaborated proceeding for its detection. If all of the above were found it is hardly necessary to go to the trouble of looking for albuminoids; the water would be unwholesome even if they were not present.—*Pharmaceutical Era.*

HOW LONG SHOULD A DIPHTHERIA CASE BE ISOLATED.

This most important question is discuosed by Dr. Prince, in the *Boston Medical and Surgical Journal:* It is a matter of vital importance, for Dr. Prince tells us of a case wherein the patient, supposed to be well, made visit to relations in Boston niue days from the date of his "getting up." One week after his arrival, a child in the family was attacked with diphtheria and died. An out-break of diphtheria, in a hotel at Nantucket, fallowed the arrival of a person just recovering from diphtheria, and pronounced well by the attending physician. One of these cases, when supposed to be well carried it to a hotel in town. Three cases of diphtheria in one family, closely followed the advent of a nurse who had just come from attendance on a fatal case.

Dr. Prince thinks that evidence goes to show that poison is retained in the mucous membrane longer than is generally considered to be the case. In lieu of definite knowledge he has adopted the arbitrary rule of advising quarantine precautions for one week after the patient appears to be perfectly free from disease. This seems to be a fairly safe rule and one that is desirable.—*Annals of Hygiene.*

NEWS AND MISCELLANY.

SOCIETY MEETINGS.

At the second annual meeting of the American Electro-Therapeutic Association, held in New York, October 4th, 5th, and 6th, the following officers were elected for the ensuing year: President Dr. Augustus H. Gœlet, of New York. Vice-Presidents Dr. William F. Hutchinson, of Providence, Rhode Island; Dr. W. J. Herdman, of Ann Arbor, Michigan. Secretary Dr. M. A. Cleaves, of New York. Treasurer Dr. R. J. Nunn, of Savannah, Georgia. Executive Committee: Dr. W. J. Morton, of New York, Dr. Robert Newman, of New York, Dr. G. Betton Massey, of Philadelphia, Dr. Chas. R. Dickson, of Toronto, Canada, Dr. J. H. Kellogg, of Battle Creek, Michigan. The next meeting is to be held September 12th, 13th, and 14th, 1893.

AN EXPLANATION.

A quack doctor stood on his wagon at the street corner selling his cure-all. A gronp of people gathered about him and he undertook to explain to them the an atomy of the throat. "My dear friends," he began) "perhaps you don't know it, but there are two passages that go from the back of the mouth to the stomach. One is called æsophagus and the other æsophagi. Now, the solid victuals go down the æsophagus and the liquids down æsophagi. Over the top of the holes is a cover with a hinge in the middle, and when you swallow beefsteak the little door over the æsophagus flies open, and the little door over the æsophagi drops down, and *vice versa* when you take a drink of coffee." This description proved too much for a farmer who stood on the edge of the crowd. Shaking with laughter; he remarked in a loud tone: "Gosh, but those doors must go flipper flopper when a fellow eats bread and milk."—*Youth's Companion.*

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY FROM OCTOBER 30, 1892, TO NOVEMBER 5, 1892.

The leave of absence granted Captain Henry P. Birmingham, Assistant Surgeon, U. S. Army, is hereby extended one month.

PROMOTION.—First Lieutenant Nathan S. Jarvis, Assistant Surgeon, U. S. Army, to be Assistant Surgeon, with rank of Captain, October 14, 1892, after five years service, in accordance with Act of June 23, 1874.

First Lieutenant Harlan E. McVay, Assistant Surgeon, U. S. Army, will proceed from Fort Wingate, New Mexico, to the camp south of Bisbee, A. T. and report to Lieutenant Colonel J. W. Barlow, corps of engineers, Commissioner of International Boundary line survey, for duty, relieving Captain E. A. Mearns, Assistant Surgeon, U. S. Army.

Pharmaceutical Products of the Farbenfabriken vorm Friedr Bayer & Co

Sulfonal-Bayer

induces sleep, free from narcosis, and sequelæ. It acts purely as a hypnotic and claims no analgic powers. Sulfonal is also of the highest value in the neuroses and is largely employed by neurologists. It is a safe remedy and its continuous use does not give rise to a drug habit. Sulfonal must be given according to directions. (*Supplied in ounces.*)

Salophen

is a new salicylo-phenolic derivative said to be so combined, chemically, as to constitute a safer and more effective remedy than either of its components, or any analagous preparation. The reports refer in the highest terms to its value in rheumatism and allied affections. Competent observers recommend it for extended trial. (*Supplied in ounces.*)

Europhen

is a complete substitute for iodoform and is a cicatrisant of special value in specific lesions, catarrhal and ulcerative diseases and all surgical conditions formerly treated by the latter preparation. It has five times the covering power of iodoform and forms an impervious coating over denuded tissues. Europhen has a faint, agreeable odor resembling that of saffron. (*Supplied in ounces.*)

Phenacetine-Bayer

continues to justify the high praise of physicians, and it may properly be considered as the best of the modern antipyretics and anodynes. In *la grippe,* rheumatism, migraine, neuralgia, etc., it is a prompt, safe and effective remedy. Phenacetine, unlike the secret mixtures announced as analgesics and antipyretics, is a true organic derivative. (*Supplied in ounces.*)

Aristol

is now widely used as an agreeable and effective dressing in all of the operations of major and minor surgery and in dentistry. It is invaluable in ulcerations of all kinds, and in burns, blisters and bed-sores. It adheres closely to mucous membranes and wound surfaces. (Aristol and "Europhen-Aristol," a combination of both remedies are supplied in ounces.)

OBJECT LESSONS IN GYNÆCOLOGY.

By W. H. LINK, A. M., M. D.,
PETERSBURGH, INDIANA.

II.

IMPORTANCE OF PRACTICAL INSTRUCTION IN GYNÆCOLOGY.

If correct theory leads to correct practice, it is no less true that a theory is often modified, if not wholly exploded, by the truthful lessons derived from an application of a false theory to a condition that repeats itself so often in the field of observation and experience that harmful results may be traced to their causes.

Errors in gynæcology have been perpetuated for lack of practical instruction. Teachers and text-books have accepted the errors of predecessors in the field and, as conservatism seldom disputes authority, it has always been much easier to teach false doctrines than to formulate, explain, and defend correct ones. The reverence for authority is always soothing to mediocrity, and falsehood lifts its hands in holy horror when its idols are rudely shattered by the advance of either truth or time.

Modern times have seen more than one "system" in gynæcology rise, blaze out and die away before the advance of clinical experience. The mechanical theory of Hewitt, which explained every ill that female flesh is heir to by displacement, had its counterpart in Hodge, who furnished a pessary by which every ill was cured. The theory of ulceration armed every physician in Christendom with a stick of caustic and a bunch of cotton, and what one put in another wiped away. "Congestion, or pelvic engorgement," charmed dreaming students on the benches for many a day, and some old drone whose back has furnished a harvest for many generations of pewees, may yet be heard putting young men to sleep, crooning out the same old drivel. On such a teacher's table, the glycerine tampon and the wad of cotton lie lovingly beside the rusty old sound and the Ferguson speculum, quaint mementoes of the Dark Ages in gynæcology and universal accompaniments of the so-called conservatism. Cellulitis, leading to, or ending in, a condition in which nature is supposed to make a plaster-cast of all the internal pelvic organs by pouring into the interstices of connective tissue, liquid cement, which hardening, holds as in a vise, the organs which it surrounds; cellulitis yet furnishes wonderful triumphs to the old conservative, who whiles away many a profitable hour by squirting hot water against the vaginal vault to soften and dissipate the offending masses. All these theories were taught to class after class of students in our medical schools, sending them forth to freshen their memories along the same line, by a peep into their teachers' text-books, should they by chance let slip any one of the three or four things learned during the course, or should they by any mishap, have forgotten some one or two of the half dozen remedies that their teachers had tried to impress upon their minds as curative in these same three or four conditions. We have all seen laceration of the cervix raised almost to the dignity of a universal cause, and the operation for its relief hailed and heralded as a cure for evils that have since been found to lie far above the cervix. Stenoses and flexions had their day when dysmenorrhœa and leucorrhœa were explained by their presence, and cured by splitting or divulsing. Thus, while one camp stretched or split the cervix for a host of evils, the other wrought cures in the same cast of troubles, by stitching up a cervix that nature had lacerated in completing a physi-

ological act. These different theories have served their day. We now have a more modern fad, which has taken possession of the imaginations of men. That is, Electricity. There is one great advantage about this agent and its votaries which no other system ever possessed. It is independent of pathology, and diagnosis is superfluous. Pain is relieved, no matter to what it is due. Hæmorrhages are controlled, inflammations subdued, discharges dried up, solid tumors resolved, fluid collections dissipated, adhesions melted away, stenoses dilated, dilatations contracted, fungosities destroyed, secretion regulated, excretion promoted, nutrition favored, anæmia abolished, plethora cured. All that is necessary is that the condition or disease attacked must be hid, either in the general abdominal cavity, or in the pelvis. The agent is too modest to work where its results and processes can be seen. The thick abdominal walls furnishing a cover, miracles can be performed with as much facility as the East Indian juggler by his manipulations beneath a piece of cloth causes a mango plant to spring up in a few moments.

None of these many theories have been entirely false nor absolutely without value. Looking back at them now, we eagerly ask ourselves for an explanation of the long continued existence of the many harmful methods and instruments which hung about the practice of gynæcology, even after experience had exploded the theory upon which they were based. The answer at once suggests itself. The absence of anything like practical teaching.

In nine-tenths of the medical schools of this country, the teaching of gynæcology is the emptiest and most ludicrous thing imaginable. In the first place the chair of diseases of women is generally filled by a man, whose chief qualification is "inflooence." He has been able to lay pipe successfully, or he has served as an assistant to the man who has just become emeritus, thus perpetuating all the hobbies of his predecessors, or worse still, he is the son of his father.

> "Thus error's triumph once begun,
> Bequeathed from dirty sire to dirtier son,
> Though ever lost, is often won."

He contents himself with what is taught in the text-book and dares not differ from his favorite authority on anything, because his own experience is a safe one only when he keeps close to the shore where the fathers have the territory well marked off in their charts. His lectures are mere paraphrases of text-books, changed enough to prevent a too ready recognition by the students, and his power of independent thought and action are limited by that great badge of mental slavery, *conservatism*. Everything not laid down in the books, is reckless daring, or conscienceless mutilation; while everything endorsed by the authority of worm-eaten, moth-inhabited, and dust-covered text-books, is denominated conservative. Students are constantly warned against the evils of attempting anything of magnitude for a long time after going into practice. In a public discussion at the meeting of one of our important societies not long since, one of the speakers, a teacher in a medical college, said that he told his students not to buy a sound for three years after beginning practice, when it would probably be safe in their hands. How much better would it have been, had he taught them the practical and safe use of the instrument, before turning them loose upon a confiding and helpless community.

A large number of the colleges teach only didactically, while a few have what they dignify by the name of clinic, which consists of bringing a patient about once a week into a large amphitheater, exhibiting a breech presentation to an admiring class at long range, while the old professor stands by with a large buttonhole bouquet pinned to his lapel and, as his assistants or internes turn the revolving table with the patient on it so that every one in the room can see, he eloquently descants on some excrescence of the vulva, or a urethral caruncle. A lot of instruments are shown to kill the rest of the hour, when every man, after taking copious notes, rushes to the next clinic. Other schools, a little further advanced, have material enough, and variety, to spare; but some old fogy occupies the teacher's chair and nullifies the efforts of patient and student alike. His armamentarium consists of the inevitable sound, its twin brother, the old cylindrical Ferguson's speculum, a bunch of cotton, a bottle of glycerine, a bottle of iodine, and a box of vaseline. The patient is put on the table, the old reliable Ferguson is introduced, then the boys to the

number of thirty to fifty are passed around the lower end of the table, and, as they pass by in solemn Indian file, each turns his head and takes a peep. He looks down into that old Ferguson and sees bottom. He does not know what it is, but he is soon enlightened by the old professor, who informs him that she has had a vaginal catarrh, complicated with an erosion of the cervix, or a swollen condition of the cervical glands. The vault is mopped with iodine, and she is told to come again. After a student has seen bottom at the end of that old Ferguson a few times, has seen the changes rung on cotton and glycerine, iodine and glycerine as often, the science of gynæcology begins to have a sameness about it that fails to satisfy an inquiring mind, and he goes away to some other clinic, where a better teacher holds forth on some other branch of medicine, thoroughly convinced that no one knows much about the diseases peculiar to women, or that the science of gynæcology is very simple indeed.

I am told by reliable persons that in one of the most respectable medical schools in a large western city, the chair of gynæcology is occupied, (not filled), by an old medical ante-diluvian, who has never done a surgical operation of any kind, either plastic or otherwise, in all his life. Such a man, no doubt, thinks that the whole science of medicine in his specialty consists in whitewashing the vagina once a day with carbolic acid and glycerine, and looking wise in the presence of his students when he meets a case that refuses to yield to the whitewash system of therapy, and who, when a case so plainly surgical that it can not be ignored, comes before him, excuses his cowardice and ignorance to himself and class by naming it conservatism. There are some schools in this country where a system of practical instruction is attempted with the graduating class, and where the student has opportunities for personal examination and treatment, and may witness an application of the necessary surgical means of relief. But these schools are the exception to a very general rule, and may be justly looked upon as harbingers only of a brighter day.

Coming home with such a mental picture before him as every student must bring from such teaching as I have attempted to describe, is it any wonder that he soon becomes wind-skaken in doctrine, sun-cracked in knowledge, worm-eaten in method, and moss-backed in practice? The literature, current and otherwise, of the day only deepens his despair when perchance he rouses from his lethargy and seeks for light. He is constantly told by the great host of conservatives that it is only given to an inspired few to do anything like surgical work. That he, being a country doctor, living close to the gum-wax tree, must send for of those great men who have drunk deep and often at the great German fountains of surgical knowledge, to do all his important work for him. He is told by some of our text-books and men who fill most of the space in our special journals, that foreign cattle all wear long horns, and that unless a man lives *am Rhein Fluss*, and bears the mellifluous name of Klopstock, Kruminshingle, or Pullminoseoff, "his name is Dennis," so far as any excellence, surgical or otherwise, is concerned. Well, the average country doctor, being limited in means as well as time, looks at the map and sees that Germania lies beyond the sea; and, knowing that a course in one of her favored hospitals is beyond his means, he settle down to the inevitable, and contents himself with becoming a feeder for Gotham or some other center, when his patients have money. When they have not and his efforts fail to relieve, they are in the hands of nature and must do the best they can.

What we country doctors ought to know, and what we are beginning to know, is that better surgery to-day is done right in the Mississippi Valley and in Philadelphia, than in Germania, or any other foreign land. That it costs nothing, or but little, to see the work. That, with proper observation, and a reasonable amount of study and preparation, within the reach of all, the country doctor has done, is now doing, and may still do anything which the exigencies of practice demand, and in as successful a manner as if he had filled his belly full of beer, and his head full of hobbies at Vienna.

The Polyclinic at Philadelphia gives good practical instruction at moderate prices to small classes, and is in the reach of all who desire a post-graduate course of instruction. There are several very eminent abdominal surgeons who are doing an enormous amount of work, and whose technique is faultless, whose results are comparable

to the best in the world, and whose doors swing open to visiting physicians at all times. Eastman, of Indianapolis, is an honor to American surgery, a bold and successful operator, has an international reputation, and is always ready to show his work to the earnest seekers for knowledge. McMurtry, of Louisville, has lately been appointed to a chair in the Hospital College in that city, and will, no doubt, draw about him a large clinic, where any attending doctor, country or otherwise, can get lessons in operative gynæcology at small cost to himself financially, and of a kind that will leave nothing to be desired, from a practical standpoint. Hall and Reed and Ricketts, of Cincinnati, are doing a large amount of the best work, which can be seen by visiting physicians whenever they apply. Sutton, of Pittsburgh, has a large Sanitarium, and does all kinds of abdominal and pelvic surgery, with results equal to the best, and, as he is proud of his work, there is no doubt that any visiting physician might profit by even a short observation of his methods. The Prices in Philadelphia are doing more abdominal surgery than any other men in this country, and publish the lowest mortality. They have a large clinic, where the daily attendance ranges from 50 to 100, and a large private hospital in which every phase of abdominal and pelvic surgery is illustrated during the year, by daily sections, on selected subjects. They are ready at all times to demonstrate to visitors the results of pelvic disease, and the marvelous results of the very highest type of American surgery. With all these opportunities, and many others not named, open to the ambitious and conscientious surgeon, there is no longer need to go abroad in order to receive practical instruction, and he, who lets his patients die for want of knowledge, has none but himself to blame for his ignorance. There is already too much abdominal work done by the few, and too little by the many.

Consumptive.—Yes, the doctor says I won't live six months if I stay here. Is your section of Florida healthy?

Florida Man.—Healthy? Half the people down there want to sell and come North.

Eh? Why?

Tired of life.—*Tid-Bits.*

CORNEAL ULCERATION AND ITS SEQUELÆ.

By ARTHUR D. MANSFIELD, M. D.,
ASSISTANT SURGEON PRESBYTERIAN EYE, EAR AND THROAT CHARITY HOSPITAL, BALTIMORE, MD.

The importance of ulcers of the corneal substance of the eye cannot be over-estimated, nor can too much stress be put upon the treatment or the early recognition of such destructive changes in the eye. No structure is at the same time so amenable to treatment and so capable of disastrous results following malpractice or tardy treatment as that seen in ulceration of the cornea.

The structure of the cornea is such that any changes whatever that affect its transparency (and all changes do impair the cornea to a greater or less extent) impairs naturally the vision of the eye affected.

The usual progress of an ordinary corneal ulcer is tolerably constant. Infiltration of the circum-corneal area followed by destruction of the laminæ of the cornea, with photophobia and injection of the conjunctival vessels and the deeper zone of vessels about the margin of the cornea, which is so characteristic of corneal troubles of all kinds—pain of the eye, both to light and touch, is always a symptom found in corneal troubles, and another annoying symptom which at this time may become very serious on account of the barrier it places to the proper treatment, is belpharospasm which is so grievous in some cases as to demand cauthotomy.

The diagnosis of a corneal ulcer is not always such an easy matter, especially in children on account of the inability of the examination to obtain a proper view of the cornea, and I would advised that the proper examination of the cornea be never neglected or thought of no consequence, for upon the proper or improper treatment is the future usefulness of the eye as a visual organ dependent. Many an ulcer of the cornea, has gone on to the complete destruction of an eye that could have been restrained had it been properly treated in the beginning. Let it always be remembered that in the treatment of an ulcer of the cornea, the first essential is to see whether an ulcer exists, its location, whether in the visual axis, i. e., before the pupil of the eye or whether peripheral,

the character of the ulcer whether deep or superficial. Often the proper view of the position of an ulcer will aid one in making a definite prognosis as to whether it will impair vision materially or not, which is a matter of extreme importance to the patient. When the efforts to open the eyelids prove futile by the ordinary means, then the use of a lid retractor will be of vast importance and considerable aid.

Is is not my intention to take up what is known as phlyctenular keratitis, which often simulates to a marked degree ulcers of the cornea, but to limit myself to the different forms of ulcers of the cornea, the treatment of the same and the effects of such ulcers when allowed full control of the organ.

Ulcers of the cornea, I take it, are classified into three chief groups which may be called superficial ulcers or those affecting the superficial laminæ only; second those penetrating deeper into the corneal substance and even through the membrane of Descemet with escape of the aqueous and hernia of iris or production of lenticular changes; third, serpiginous ulcers having a curved shape, often extending around the periphery of the cornea in such a manner as to give it the name of serpiginous.

Taking up the ulcers in the order in which I have divided them I will endeavor to give the history and treatment, reserving the sequelæ for my closing remarks.

(1.) Superficial ulcers are as a general rule very simple in their nature and very readily yield to treatment; the difficulty really lies in the fact of their recognition, often being very difficult to see by the ordinary means and in many cases requiring the use of a strong lens to throw oblique rays of light upon the cornea to detect their presence. I have often been struck with the different symptoms corneal ulcers of this character produce and have been at a loss to account for such manifestation of different symptoms from such simple ulcers. I say I have been at a loss to account for it upon other grounds than personal idiosyncrasy and predisposition. In some cases of superficial corneal ulcers there may be none of the usual symptoms, little or no pain, or photophobia, very small amount of lachrymation, eyes open, and, judging from the ulcer, more pronounced symptoms would be expected but few or no symptoms appear.

In another case the patient comes with head held down, eyes closed, complaining bitterly of the smallest ray of light, suffering severe neuralgic pains in and about the eye with profuse lachrymation, leading us to expect a severe and extended ulceration of the cornea when upon opening the eyelids forcibly we find only a small ulcer. It is these facts that lead one to rely only upon the ulcer "per se" in the diagnosis and prognosis of the case. Nothing I take it is more deceptive than a corneal ulcer when a diagnosis is made from the symptoms above without actual evidence of the ulcer itself. The diagnosis of the ulcer should then be made upon the evidences of proper inspection alone and when so made an intelligible prognosis and rational treatment given and followed. These superficial ulcers, may, as I have said, only affect the superficial layer of the cornea and do in point of fact, being occasioned usually from a traumatism of a slight nature such as a foreign body or blow in the eye which only wounds the cornea but does not penetrate its substance. Irritating substances often give rise to corneal ulcers of this character.

The treatment of these ulcers is simple in the extreme but simple as it is, may lead to very serious results if not followed out properly and early. I have found the use of eserine in this form of ulcers very good if much photophobia exists, if not the use of the yellow oxide of mercury salve in the proportion of four grains of the yellow oxide to one drachm of vaseline and making a delightful unguent as well as stimulant to the ulcerated parts, in connection with this the use of mercury drops, the corrosive sublimate being used in the proportion of 1:3000 to 1:5000. The drops to be used often during the day, perhaps every two or three hours, while the salve is to be used only upon retiring at night. Should much pain exist the compress and bandage will be found useful in allaying the irritation produced by the movement of the lids. Usually these ulcers yield readily to treatment and leave no opacity to mark their past presence. Sometimes when directly over the pupil they occasion considerable discomfort and dimness of vision.

When these superficial ulcers gain the advantage either from neglect on the part of the patient, or from ignorance on the part of the physician, they pass into the graver form, the deep ulcers which form

the second group of my classification. (2.) Deep ulcers of the cornea are the ulcers. These cause trouble both to the general practitioner and specialist. Deep ulcers are caused by the bursting of a phlycter on the cornea, by abrasions which penetrate the corneal substance, contused wounds, foreign bodies, etc. Deep ulcers are also seen following such diseases as small-pox, measles, etc. In paralysis of the fifth nerve we see occasionally ulceration of the cornea.

The appearance of a deep ulcer is characteristic, presenting a well-defined concavity with the edges opaque from the infiltration of the leucocytes, and in healing usually form scar tissue which is opaque and gives the typical cloud which is seen so frequently following corneal ulceration.

The symptoms of a deep ulcer are the same as those seen in a superficial ulcer but of greater severity, increased photophobia, copious and profuse lachrymation with pain more or less severe in and around the eye.

The ulcer may be large or small and may be situated about the periphery or may be over the papillary aperture and when so situated serious trouble will result as to future vision. The ulcerative process may extend so far that there is destruction of the corneal substance up to the membrane of Descemet and then we have a protrusion or hernia of the membrane which may or may not rupture and be followed by iritic hernia; this condition which I have seen not unfrequently is known as "keratocele." That which follows deep ulceration most frequently is opacity and of course varies in density and opacity with the amount of corneal substance affected by the inflammation. Omitting the treatment for a while we will pass to the next form of ulcers. (3.) Serpiginous ulcers usually occur in elderly persons and those advanced in years where the vitality of the structure is below par and especially the cornea, which shows this impairment of vitality by the "arcus senilis." This form of ulceration is mostly in a chronic form and advances slowly in a crescentic form which gradually cuts off the proper nutrition of the cornea and as a consequence sloughing, in long neglected cases followed most surely by pan-opthalmitis.

The acute symptoms of this form of ulceration are not always the most imperative and on this account the neglect is excusable on the part of the patient. The ulcer advances peripherally, destroying as it advances, and forming scar tissue in its trail.

Treatment when properly instituted and observed can check its progress and preserve the eye from its dire consequences, but the mal-nutrition of the parts as a general rule prevents any brilliant achievements.

To return now to the treatment of these ulcers of the cornea. We have at least six distinct objects to have in view in the treatment of ulcers in general be they superficial, deep or serpiginous.

1. Stimulate the ulcer to a normal and healthy condition.
2. To ease eye-pain and produce sleep when required.
3. To protect the ulcer from friction against the eyelid and from strong light.
4. To diminish intra-ocular tension when necessary.
5. To apply a seton or other counter-irritant when needed.
6. To improve the general constitution.

Taking these objects *ad seriatum*:

First.—The ulcer can be stimulated when stimulation is needed which is in chronic and indolent cases. If there is any one drug indicated in corneal troubles it is mercury in any of its various forms. The best mode of application of mercury in stimulating corneal ulcers is in the form of the yellow oxide of mercury ointment, the yellow oxide is used in preference to the red oxide because the former is less crystalline than the latter, and consequently less irritating to the eye. Calomel may be used as a powder, but it very often causes such intense pain that it must be discontinued. A very weak solution of eserine may be used with advantage in lessening the photophobia and at the same time stimulating the ulcer to renewed activity—warmth applied externally also aids materially in stimulating the ulcers.

Should these fail in stimulating sluggish ulcers into activity resort should be had to the use of the mitigated stick of silver nitrate or the galvano cautery or simply scraping the edges of the ulcer with a sharp instrument or small curette. Caution need hardly be enjoined upon any one using such severe means, and caution should be especially exercised in using the

cautery, for puncture of the cornea is not an infrequent sequence of such means.

SECOND.—To ease pain and produce sleep if necessary. The use of hot fomentations and warm compresses, the use of the Japanese hot box, warm applications of a solution of poppy-head tea, subcutaneous injections of morphia in the temporal and orbital regions give relief temporarily, the use of a solution of atropine in the eye also aids wonderfully in relieving pain.

THIRD.—To lessen the irritation caused by friction of the lids upon the inflamed and ulcerated part.

A large shade should be worn to protect the eye from light and thus alleviate the pain consequent upon such exposure. If this should fail then the eye should be bandaged up with a slight compress to hold the lids in position and prevent motion.

FOURTH.—To diminish intra-ocular pressure when necessary. This is indicated occasionally in deep ulcers when hernia of the iris and rupture of the membrane of Descemet, is only a matter of a short time anyhow. We can diminish intra-ocular pressure by the use of eserine which not only lessens intra-ocular pressure but stimulates the ulcer; in cases of hypopyon the use of eserine often acts very quickly. The second and sure method of diminishing intra-ocular pressure is by parcentesis of the anterior chamber, hernia of the iris and wounding of the lens is to be particularly avoided; should the hernia of the iris persist, iridectomy should be performed while the wound is open. In some cases the ordinary paracentesis is less preferable to Saemisch's operation which consists in passing an ordinary long Graefe cataract knife through the ulcer and the anterior chamber, to as great a length as the surrounding infiltration exists. Every twenty-four hours the wound should be opened so as to allow the escape of purulent matter from the anterior chamber and should be so opened until suppuration diminishes.

FIFTH.—Counter irritation is an extremely valuable adjunct in the practice of ophthalmology and I have seen the seton in the temple clear up a cornea that seemed so cloudy and vascular as to almost dishearten one of its ever regaining its transparency. I have in mind now distinctly two such cases of recent occurrence. The best seton is horse hair or stout thread, and can be inserted in the temple or in the nape of the neck and should remain for at least two weeks after the disappearance of all ulceration. Blisters can also be used though with less efficacy. Artificial leeching can also be used advantageously.

SIXTH.—In reference to the improvment of the general health of the patient I need say very little. Good food plenty of out-door exercise, hygienic surroundings, tonics, iron, quinine, strychnia, cod-liver oil, phosphorus, etc., such remedies as the nature of the case may demand. I have already taken up more of your time than I expected and will hasten to enumerate some of the sequelæ of ulcer of the cornea.

Perhaps the nost common sequel of corneal ulceration is opacity. If the opacity is dense and large nothing can be done for it other than making an artificial pupil if any clear cornea exists and if none exists then tattooing the cornea for cosmetic effect can be done. Should the cloud be small and not very dense, the continued use of calomel powder for a long time will clear the cornea but this can only be done in very pale opacities, and used for a long time. Keratocele is another sequel of deep ulcer of the cornea and may be followed by hernia of the iris or in the case of small children, especially in the ulceration of ophthalmia neonatorum, pyramidal cataracts may form from the contact of the lens with the ulcerated cornea. I cannot take your time to so describe all these changes and the treatment of the same, but must confine myself to the subject matter. Astigmatism may follow a corneal ulcer and the contour of the cornea may be changed as to make it very difficult to help by means of glasses.

Staphaloma anterior may follow from severe ulceration of the cornea when the eye is hopelessly lost. Hypopyon is seen very often following corneal ulcers, followed by iritis in some few cases, and sometimes by panophthalmitis. When such is the dire results of corneal ulcers little or no hope can be entertained for the restoration of the eye to its normal condition.

Summary: Corneal ulcers are to be treated by the use of mercurial ointment in connection with a weak solution of corrosive chloride of mercury. When sluggish and chronic the ulcer is to be stimulated by the various methods enumerated and remembering that in the vast majority of the cases the sequelæ are to be accounted for by some neglect either on the part of the patient or doctor; also that opacities the sooner seen the sooner helped.

GONORRHŒAL ARTHRITIS.

By PROFESSOR CHARLES CAREY, M. D.,
BUFFALO GENERAL HOSPITAL.

This patient was well till four years ago when he had inflammation of the bowels, from which he made a good recovery. Neither his occupation, that of a candy maker, his family history, nor his previous personal history—so far as it can be elicited—has any bearing on his present trouble. Two weeks ago he entered the hospital in a bad condition. His shoulders and hips had been swollen for a week and others joints became involved. His knees were enormously distended and too tender to admit of any manipulation. They were at least twice their present size and the diminution will undoubtedly continue. The disease has shown no tendency to fly rapidly from one joint to another, but rather to linger where it has once invaded. On making pressure on the patella, I can bring it with a click against the femur, showing that the swelling is beneath the patella and floating it forward. The sense of fluctuation, also, is distinct Both knees are affected and nearly equally. The ankles have been involved and on the dorsum of the hand there was a swelling running along the line of the tendon sheathes. The wrists are still a little sore. The patient cannot extend the arm at the shoulder but I can extend it for him without causing him pain. This implies that the trouble is in the tendon sheathes or bursæ lying between the muscles and not in the joint itself. I have seen similar cases in which the malady was limited entirely to the different bursæ, as the one beneath the tendo patellæ or at the point where the tendo Achillis rounds the heel. In other patients, a touch on the tip of the elbow would be very painful on account of the location of the bursa there. The urine is normal, in this case, except for the presence of a small amount of pus. There has been a urethral discharge which, the patient says, he did not notice until he entered the hospital. Venereal history is denied.

This is an illustration of a disease which is, fortunately, quite rare. It is a gonorrhœal infection of joints. When this boy of 20 entered the hospital, I was inclined to discredit his statement that he had not known of the presence of a urethritis for the discharge looked to me as if it had existed for some time. It had been present so long that it had involved the tissues outside the urethral canal in a prosthitis and a balanitis and the thickening was so great that the under surface of the inflamed prepuce and glans penis seemed, at first sight, to be covered with chancroidal sores. This external inflammation was, therefore, purely accidental and if the man had been careful and cleanly in his habits, it certainly would not have occurred. His own tendency to distribute the disease was also manifested by the fact that he had a bilateral gonorrhœal conjunctivitis, particularly marked in the right eye but not of severe grade in either. The right conjunctiva is still engorged and reddened but there is little purulent discharge. The very fact that this inflammation has not been more destructive leads me to believe that this man's gonorrhœa was old and had, in a measure, lost its virulence before he accidently inoculated his eyes. There is no type of conjunctivitis which compares in gravity with the acute gonorrhœal form for the sight is sometimes utterly destroyed within twenty-four hours after the first inoculation.

It was no trouble to stop the balanoprosthitis and the urethritis. The inflammation of the glans and prepuce subsided in a very hours and had entirely disappeared in the course of two days under the simple treatment of frequent irrigation and cleanliness aided by powdering iodoform between the glans and the foreskin. The epithelium of those parts tends to recover its normal condition for it is not nearly so sensitive as that of the urethral mucous membrane. Sometimes, on account of the thickening of the foreskin, if retracted beyond the glans, it will remain in the condition of paraphimosis and you must guard against adding this to the complications already existing.

I wish to call your attention particularly to the articular inflammation. This has been considered to be purely rheumatic but it is not so, for patients without any tendency to rheumatism will develop this arthritis almost immediately after contracting gonorrhœa. This patient has never had anything suggestive of rheumatism except that last winter he suffered occa-

sionally in the morning from a slight pain in the left knee. It has been observed that men after recovery from an attack of gonorrhœal arthritis will have a second attack precipitated by a subsequent urethritis. Furthermore, the frequency with which bursal and tendon sheaths are involved in arthritis following gonorrhœa, the relative absence of pain, the lack of sudden metastases, the comparatively low temperature—this patient's highest temperature has been only 102° in spite of the enormous swelling of the joints and finally the reluctance with which this trouble yields to treatment, established its claim to be ranked as a distinct form of joint affection. You need not be surprised if your patients become weary of your attempts at curing them and after you have seen two or three cases of gonorrhœal rheumatism, you will dread to see one enter your office again.

We may get a hint as to the pathology of this form of joint trouble by referring to a similar arthritis which sometimes follows scarlet-fever. It is not so very uncommon either, for articular inflammations to come along in connection with some others of the higher grade of infectious maladies. Such troubles, therefore, are rather analogous to pyæmic metastasis to joints although it is very rarely that the synovial inflammations assume a purulent form.

This man has not only had the synovial membranes affected of both knees, ankles, shoulders and many tendons but he has also had an endocarditis. This is, comparatively speaking, not an uncommon sequela of scarlatina but it is very rare to find such an illustration of the analogy to true rheumatism in gonorrhœal arthritis. When this patient entered the hospital he had quite a roughened first heart sound amounting to a murmur but, though still present, I am glad to say that it is diminished in intensity. This points to the fact that the structures in the heart which are analogous to the fibrous structures of joints are involved also.

What is the treatment to be carried out in these cases? The first step is to cure the urethral discharge and thus remove the source of the virus. This having been accomplished, you will find that the arthritic trouble is one of the most lingering and annoying, involving one joint after another in spite of the most careful observance of hygienic principles and of tonic and sustaining treatment. Although the disease is not absolutely incurable, it lasts till both yourself and the patient are tired of the treatment. Ricard, a venereal specialist who is much quoted to-day, said that he believed the infernal regions for doctors would be full of just such annoying cases. If these patients have a recurrence of the gonorrhœa—as such men are apt to have—the joint trouble is lighted up again and intensified. Another unfavorable circumstance is that these men do not want to acknowledge their trouble, they are not, as a rule, as sick as this patient has been and they are not compelled to give up, but they continue to walk about though lame; they become weak and anæmic but they keep going, this is one of the principal reasons for the chronicity of the malady. The chances of success are better if you can begin the treatment early and keep the patient in bed. Splinting the joints affected, secures local rest and some even recommend a plaster-of-Paris bandage, which is rather inconvenient and quite unnecessary. Although it is sometimes necessary to confine the limb in a fixed position, slightly flexed, it would have been impossible to do so in this case on account of the multiplicity of joints involved. The patient, however, has been lying quietly in bed and the inflammation has subsided rapidly.

If the disease is limited to a single articulation or to a few, mercurials may be applied locally. You will find slight use for alkaline salts except to secure one or two evacuations of the bowels daily, and for this purpose Rochelle salts may be employed. Salol will give as good results as any drug. This man was placed upon salol immediately after his admission to the hospital, being given two grains three times daily—rather small dosage. Recently we have also given him iron on account of his anæmia. Up to the present, the case has gone on very well and the degree of absorption from the knees is surprising. A latent lameness will, however, probably follow his recovery. In my opinion this is the worst of all the forms of venereal disease and I would rather see any one in whom I am interested, affected with several of the others than with this. The tendency manifested in this disease is liable to be seen in the symptoms of puru-

lent absorption from abscesses or ulcers wherever located and whenever pus may subsequently be formed. Women are not particularly subject to this disease because the mucous membrane of the vagina is not favorable to the absorption of the gonorrhœal virus and because the female urethra is much shorter than the male and lined with far less sensitive epithelium. The male urethra, too, has pockets well adapted to retaining for long periods the gonorrhœal disease. Even in men, however, gonorrhœal arthritis is not a common disease.

A CAUSE OF PROSTATITIS.

By J. W. IRWIN, M. D.,
LOUISVILLE, KY.

I do not intend to speak of the general causes of this disease; my remarks will only apply to prostatitis following bicycle riding.

Within the last eighteen months five cases of prostatitis have come to my notice, which could be traced directly to the pressure on the prostate gland by the saddle of the bicycle. Four of the subjects have passed the years of middle life, and one is in his teens. In all cases the phenomena presented by them were very similar in character, and a general description of the cases, will, I hope, suffice.

After riding the bicycle for a few hours, during the act of micturition a feeling as though the vesicle end of the urethra was raw, was experienced; then a full feeling behind the scrotum came on which was unattended by pain. Inordinate and persistent erections of the penis, coming on at short intervals and lasting three or four days was the most unpleasant feature observed.

The urethra during the act of micturition felt raw and tender under pressure; weight and some dull pain, was felt in the testicles. There was no discharge from the penis at first, but after two or three days a little moisture was observed coming from the meatus urinarius. The discharge seemed to be very thin and colorless. The desire to void the urine more frequently than normal was present while the trouble lasted.

The treatment advised was saline laxatives, and the free use of water internally. For the relief of troublesome erections of the penis, mono-bromide of camphor in large doses was advised. This course of treatment together with the removal of the cause, gave relief in from five to seven days.

In presenting this report for your consideration, I do so believing that others have observed similar phenomena following the use of the wheel-horse.

When time, which regulates the fashion of the hour, has been consulted, who knows but one of the most annoying troubles which the male subject has to bear, may be brought on prematurely by pressure of the bicycle saddle on the prostate gland? Certainly urethritis extending into the bladder has resulted from its use in the cases reported.

TREATMENT OF DIPHTHERIA.

By JAMES E. PRYOR, M. D.,
OCEAN CITY, N. J.

There are so many drugs employed in the treatment of this disease and so many opinions regarding it that the physician is often at loss to know just what course to pursue. Without going into the pathology and diagnosis of diphtheria I shall briefly give an outline of a plan of treatment, which I have found most rational and efficient. On discovery of a severe sore throat without waiting to make any fancy distinctions, I order a purge of calomel, from five to fifteen grains, to be repeated, if need be, until the stools are green. A good adjuvant is castor oil, containing twenty to thirty drops of turpentine. This active purgation, should not be repeated, as it does all the good it can do the first time. If it turns out that you have only a case of common sore throat no harm has been done. I treat all cases of sore throat exactly as I do diphtheria and have never regretted it.

After free purgation, I order the throat sprayed every half hour at first, with a solution of hypochlorous acid, made thus.

℞ Potasss chlorat ..... ʒ i
Acid muriat..... c. p.
Mix. Let stand 2 minutes then add
Aquæ Destillat..... ʒ vi
Mix. Sig. Spray:

If a gargle is desired, the same is used, diluted with an equal quantity of water.

Medicinally, I believe in, and have had best results in using tincture of iron in doses of ten to thirty drops every two hours, also one to two grains of quinine every three or four hours, with a milk diet, which on the whole, I think is the best, yet the patient may be allowed to drink strong lemonade, coffee, orange juice, or pineapple juice. The latter is said to contain a digestive ferment which attacks the membrane, this may or may not be true; but it certainly does no harm.

Locally, I order the throat enveloped in several layers of flannel, saturated with lard and turpentine, to be kept on. I strongly condemn the use of poultices, which so many are apt to apply, especially anxious friends.

Rather apply cold, as ice retards the growth of the bacilli. Heat favors them. Again, never give the patient a solution of chlorate of potash to drink. It is death to the kidneys.

I have found peroxide of hydrogen useful, especially when the disease invades the nasal passages. I have had excellent results from its use, under these circumstances, but have not much confidence in it as the main part of the treatment.

Whiskey and brandy should be reserved for the struggle, when the blood poisoning attacks the heart. It should then be used boldly and unsparingly.

Inasmuch as the membrane is a great source of danger by impeding respiration. We should always hold ourselves in readiness to perform tracheotomy.

We should not allowours e diphtheria and be deceived by favorable symptoms. The danger-line is very broad and extends far over into convalescence. Do not allow the patient to make any exertion that can possibly be avoided as the heart sometimes lets go all holds when the patient is to all appearances quite out of danger.

Right here let me say: Don't for any reason use antipyrin, acetanilid, phenacetin, or any other depressing drug. Save and cultivate every ounce of the patient's strength. If such drugs are used, you may as well hunt up the nearest undertaker.

I have said nothing about the hygienic surroundings and necessity for isolation of patient, taking it for granted that every physician is fully conversant with the fact.

MEDICAL LEGISLATION.*

By S. C. TOWLER, M.D.,
MARIONVILLE, PA.

The State Medical Society, has placed itself squarely, and earnestly in favor of a State Board of Medical Examiners, for Practitioners of Medicine, etc. It is pertinent, at this point. to inform laymen, and some doctors, what the State Medical Society is. It is the representative body, directly of,in round numbers,2500 doctors, composing the county societies, and indirectly, of 6000 regular physicians, in this State. Within its membership are found, the most eminent medical men of the Commonwealth, men of national reputation, and second to none in their profession. The State Society has been noted and indeed blamed, for its conservatism. It has been slow to move out of well-beaten paths, slow to give countenance to theories, doctrines or legislation, unless well-founded, proved and necessary. It does not lend its aid, or give its support to any man, or set of men, but has with dignity stood for the profession as a whole, regardless of faction. No man, be he ever so eminent, who appears before it, with theory or line of treatment, is above its kindly criticism, no man, in its ranks, so humble, but his ideas can have place, and respectful hearing. When such an organization places itself on record, in favor of an examining board, it means more than "something;" it means much. It seems that this learned and conservative body has been forced to the conclusion that the present law is not sufficient to protect the layman from incompetent and ignorant practitioners. When we consider, that, under the law of 1881, no person in 1892 can enter into and begin the practice of medicine without a diploma from a legally chartered college, the innovation must be startling to the uninitiated. For it means, not only as stated above, but also, that in the profession itself, diplomas are at a discount.

What a criticism on the profession! What a sarcasm on medical colleges! "What?" asks the layman, "Is the sacred sheepskin, that hangs in my family doctor's office, with all its glory of ribbon, and seal, and long list of professors' names, not evidence of his fitness for his profession." The State Society by its attitude answers,

*Read before the Butler County Medical Society.

"We do not know the merits of your particular doctor, nor do we condemn his diploma, but we do know, that as a rule diplomas are not sufficient evidence of medical education, nor a safe thing for a layman to tie to, and we cannot ask for a law that discriminates between colleges." All well-posted physicians know why the State Society has been forced into this position. It is because so many medical colleges, bid for students, by easy matriculation and graduation. It is merely a question of obtaining fees, in colleges of this class, not of turning out first-class workmen.

In spite of our democracy and republican form of government, Americans have a passion for titles. We have more Generals, Colonels, Majors and Captains, more Judges and Esquires, more Reverends and Doctors, and less plain Misters, I think, than any nation on earth. In this array of American titular gentlemen, "the Doctor," stands high, very high socially. In Great Britain and Europe, the physician stands about on a par with the tradesman, seldom among the gentry. Here there is no assembly, amongst high or low, to which "the Doctor" is not a welcome and invited guest. It is no wonder then, that the aspiring American seeks admission to its ranks, and in the seeking, in too many instances, the notoriety is what is aimed at, its almost divine mission, made a secondary consideration if indeed considered at all. The aim being selfish, it follows, that the aspirant seeks the mode most easy of access, and finds it in the college, that is willing to sell its honor and its name, for a price, regardless of consequences to society or the great wrong to a noble profession.

To this class of medical men, "the graveyard" is a joke, "buried his mistake" is funny, and "Who has been butchered now?" the essence of wit. Did the layman know the danger he is in, the narrow escape his children have made, aye, the pit of death into which his loved ones have fallen, through the ignorance of incompetent practitioners, he would not laugh at the doctor's mistakes, but would shudder in horror at the slaughter. Do I exaggerate? You who surround me to-day know I do not.

In this County of Butler I stood by the body of a woman, and as the post-mortem progressed, men turned pale, as that worthy surgeon, Dr. R. S. Wallace, exclaimed, "The scoundrel who did that ought to be hung." There before us, was a wound, from vagina to abdominal cavity, through which the hand could be thrust, telling an awful story, of shock, hæmorrhage and death. The practitioner who made that wound, had been trying to force a pair of placental forceps into the os uteri, and had madly and ignorantly pushed the instrument through the cul-de-sac above. He was not hung, indeed I believe he is practicing (?) yet.

My attention was called not so long ago to a case of severe aud protracted postpartum hæmorrhage accompanied by convulsions. The graduate in Medicine who was called, saw the stream of blood, so great that it soaked through the mattress, and trickled across the floor, he saw the clenched hand, and set teeth of the unconscious patient; and he remembered that somewhere he had read or heard of venesection in puerperal convulsions, and regardless of circumstances or condition, he opened a vein in the arm. Of course, death ended the scene, and yet the young husband, in relating the circumstances to me, said, "I suppose that all was done that could be done to save her life." It is not necessary for me to multiply cases, or enlarge on this point, cases more or less similar are familiar to you, to say nothing of the absurdly ignorant answers given by graduates of medicine before U. S. and State examining boards. It is a sad but important fact to note, that 20 per cent. of graduates are rejected by State Boards and 68 per cent. by the U. S. examining boards. Such results are a disgrace to the profession, and the issuing of diplomas to that class of graduates is dangerous to the community at large, and a direct blow and injury to the honest practitioner and student who has worked hard to earn his well merited degree. Besides this class, there are those who hold fraudulent diplomas of crank schools. I have here with me a copy taken from the records of Forest County, of a diploma of the "American Health College" of Cincinnati, O., legally chartered in 1874. This precious (?) document, not only constitutes the holder, a "Doctor of Medicine" according to the Vitapathic system, (whatever that may mean) but constitutes him a minister. It authorizes him to preach, solemnize marriage and attend funerals,

etc., etc. There are people, and not a few in number, who think that such a blanket diploma as that, "is great medicine."

All this is more than sufficient reason why the State Society has taken the stand it has for additional legislation. The form of bill as introduced in the Senate, and so ably advocated by our distinguished fellow member, Senator Showalter, is the style of bill approved by the State Society. This bill was so fair and honest, so just to all concerned, so free from sectarian bias, and so liberal in all its provisions, that no just reason has ever been given for either its amendment or mutilation in the House. The bill left the selection of members of the board to the common sense judgment of the Governor, and Senate. It asked for no favors for regulars, nor demanded discrimination against Homeopaths or Eclectics. It interfered with no existing practitioner who was legally registered under the Act of 1881. It simply threw a wall of protection about the future, and asked that the practitioner should be what he claimed to be, "competent to practice his profession," and nothing more. Could anything be more reasonable, should anything less be asked?

The objections to this bill came from various sources. First in order was that from the sectarians, *i. e.*, the Homeopaths and Eclectics. They demanded that they should be recognized on the Board. There was nothing in the bill to prevent their recognition, so the demand was a special plea for class legislation. Seemingly fearful that they might be ignored by the Governor in the appointments, they demanded that this recognition should be compulsory. What a position for medical men to take. The advocates of these schools appeared before the Committee of the House having the bill in charge, and boldly claimed the glory of all the advancement in medicine, and all the discoveries of modern therapeutics. Yet they sank themselves so low, as to seek to compel by legal enactment, the recognition they were fearful their boasted professional triumphs, would not accord them. In short they were afraid to stand on their merits alone. If any think this severe, let me remind them, that after the amendment of the bill, by placing (most unjustly) three Homeopaths, three Eclectics and three Regulars on the board; thus giving 1075 Homeopaths and Eclectics, six representatives, and 6240 Regular physicians only three representatives, that even then with all this advantage, the advocates of these schools, appeared on the floor of the House and lobbied against the bill. So their real position was against any examining board whatever, but if one must be had then compulsory recognition of their schools. I say again, that the situation proves, that they were not willing to stand on merit alone, nor subject their graduates to the same test applied to the regular. Let me here note that the word "Regular" is used only for distinction from the sectarian. The "Regular" is simply a physician. He claims no dogmatic distinction, is bound by no iron-clad theory, but is free to choose his remedy when and whence he will. Some of our own people do not seem to known that the appellation of "Allopathist" was an invention of Hahnemann, the Apostle of Homeopathy.

It may be argued that the sectarian physicians fought the examiners' bill in the interests of their own bill, known as the "Medical Educational Bill." Their position won't stand examination on that either. The Medical Educational Bill was referred in the House to the Committee of "Health and Sanitation." Of those members composing that committee ten were regular physicians, yet they gave the sectarians most respectful hearing and reported the bill promptly "as committed." It was in the power of these ten regulars to have juggled with, or even killed that bill in committee. On the contrary, these ten regulars, of whom I was one, assured the sectarian gentlemen, that the bill should have a fair show and open discussion in the House. It was read a first time and then its friends let it quietly drop. The entire history of Medical Legislation in the last session, shows on the part of the regulars, open and above board desire for discussion of these bills on their merits, and on the part of the sectarian, simply flat-footed opposition. The opposition in our own (Regular) ranks, was largely uncalled for. The principal objection was, that the professors in our colleges should be the most competent judges of the qualifications of the graduates, and the degree given should be sufficient evidence of ability. The answer is, no one questions that they should be, but the bald fact remains that they don't examine and there is no process to compel them to except in the legislation proposed.

If ignoramuses were not turned out by colleges, as graduates, then the State Society would never have asked for the legislation. Again, it was objected, "that midwives could still practice," Every country physician knows, that it would be a great wrong and hardship to the suffering woman in labor, to forbid the attention of another woman, when the nearest and perhaps only doctor lived miles away. Let it be remembered also, that a woman in confinement, is just as safe in the hands of a woman, who has had children and thus some practical experience, as she would be in the hands of that "Graduate," who answered that "the best way to facilitate the expulsion of the placenta, was to let the woman get up and walk about the house five minutes after the delivery." The fact is the scope and intention of the bill is not properly understood. It is not the neighbor who assists a wounded or sick man in an emergency; it is not the woman, assisting her sister woman in her pain and anguish; it is not the painstaking and honest practitioner even though he be somewhat behind the times, that the State Society is after, not at all. It is the man who claims to be, *what he is not*, the man whose qualifications for practice are simply on paper and nowhere else. The man who is dangerous, incompetent and unworthy, and yet who flaunts his diploma in the face of worthy practitioners and a confiding community, saying, "this is my authority, what are you going to do about it?" I have in my possession, specimen copies of the examination sheets for graduates asking admission to the Army and Navy. They cover the nine common branches, taught in our colleges, with an average of eight questions in each branch; with few exceptions the questions are plain and practical, yet sixty-eight per cent. of graduates fail to pass. If the diploma was sufficient evidence of qualification, the Army and Navy Board would not require the additional examination.

It is pertinent to here remark that the life of the civilian is just as valuable as that of the military, and as much to be protected. It is well to remind those in our own ranks, members of county societies, who opposed the bill, that their position is hardly fair to the majority. In a liberal profession like ours, we can cheerfully concede that no man is compelled to accept the opinion of another. That even majorities may be wrong and minorities right. Yet every man of common sense must acknowledge that as long as he is in the organization, it is his plain duty to submit to the majority and not join with its enemies in frustrating its purposes. The only exception to this rule is when majorities have been gained by fraud and misrepresentation.

The majority of the County Medical Societies, is undoubtedly represented by the majority in the State Society, and opposition to its plans by aiding those outside the organization, is little short of treason in the camp.

Now we come to the objections raised by members of the Legislature. First; "The profession is not united in asking for this legislation." The answer is, that it is impossible to not have, in 8,000 doctors in the State, some kickers—and some of them would kick at most anything. But the bill is not for the protection of Doctors, save incidentally, but for the public, and if good legislation should pass regardless of some Doctor's opposition. This leads us to the next objection, viz., "The public has not demanded this legislation." I can't repress a smile as I answer, that, if no legislation was considered but that demanded by the public, the General Assembly could meet, transact such business, and adjourn after a four weeks session. Legislation is called for, more often by leaders of thought than by public demand. There was no public demand for the law of '81, yet so far as it goes, it has popular approval, and is a good law. There was no public demand for the Pharmaceutical Examining Board, yet it has popular approval, and its work has been good and protective of life and health. "It is perfectly safe to say that no well posted layman will object to this law, for it is for his benefit and it would meet with almost universal commendation. The next objection was, "If the diploma is not evidence of ability why should the graduate be obliged to have one at all?" That is the hardest objection of any to answer. Having taken our position on the competency of the applicant as ascertained by the board and discounted his diploma in advance, to be consistent, we are compelled to admit that if an applicant can pass the examination before his diploma is presented, he should not be

compelled to have one at all. For instance, a member said to me, "Doctor, suppose a young fellow undertook to educate himself under a preceptor; he procures his books, studies hard and becomes able to pass the examination, why should he not have the chance?" I answer, "He should, that feature of the bill can be omitted if it was at all called for without prejudice to the essential parts of the bill." It would be very rare indeed that the board would be called upon to examine such an applicant, so rare indeed that save for the consistency the objection might go unanswered. On the other hand with that feature retained it compels colleges to see that students are capable of passing the examination. It strengthens, endorses and makes good the diploma of the applicant, and is a help to him in medical standing. So that while that feature might be omitted, it is very much better to retain it. On the same line is the objection that "The members of the Board should not be compelled to have diplomas." The answer is that while it is true diplomas are not sufficient evidence, yet it is part of the evidence needed to form a Board intelligently, it being the standard up to the time of the change. To it is added the requirement of ten years practice, a feature of much practical importance. It is to be remembered that the Governor is expected and would doubtless make careful inquiries before making appointments to the Board.

That brings us to another objection, that this ten year feature cuts out the younger graduates from appointment. Well! brethren there will be left more than 7550 to condole with you and it's hardly worth while kicking over a little matter like that. Another objection is, "That it will hurt the smaller colleges." I fail to see why. Every college professes to send out its students as "competent doctors." That is all this bill requires them to do. High or low, great or small, rich or poor, in person or college all this bill asks to know is this "Is he qualified?"

In order to effect this legislation, it is necessary that the profession be in accord and urge its enactment. It is necessary also that the public be informed of the true state of the matter. To this end not only the medical press, but the secular press as well, must be enlisted in this work. Few laymen see a medical journal and take no interest in it when they do. They can only be reached by the public press There are few papers but would be glad to have a letter on that subject from the leaders of thought in the profession. Let these leaders come boldly to the front and a revolution in sentiment will take place. The quack and charlatan use the public press, while the worthy men of the profession write an article on humbugs for a medical journal and then sit down and growl at the growing influence of the pretender. To educate the people, to show them "what they are at" we must use the means best adapted to that end and not travel only in paths they never follow.

I have gone into this subject somewhat exhaustively, for this society has not only the honor of having the only member of Senate or House, in the person of Dr. Showalter, who has succeeded in pushing such a bill through the body of which he was a member, but the State Society Legislative Committee has placed two of our members as its associates, viz., Dr. A. Lusk and myself, so it behooves us to keep up the society record in the good work. Finally as a means of success, bickerings and jealousies in our ranks must cease. Let us remember "whereunto we are called." Our solemn responsibilities not only as healers of diseases but educators in hygiene. For many of us, I know, the way is rough, the road hard to travel, with but here and there a flower, and there and here a resting place. Cruel injustice has wrung kindly hearts and base ingratitude has added its pang, yet he who loves his fellow man, ministering to his sufferings, is loved by his God and meets that God's reward.

A PRESCRIPTION FOR YOUNG PHYSICIANS.

According to the *British Medical Journal* a distinguished Vienna professor gives the following prescription to all young physicians who call to take leave of him before embarking on their professional career. R. Veritatis, humanitatis, fidelitatis, aa infinitum. Misce. Ft. elixir vitæ. Signa: To be used constantly throughout life. It is easy, perhaps for most men to start with a good stock of this spiritual elixir, but the difficulty is to find an apothecary who can dispense the prescription when the supply has run out.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting of November 3, 1892.

The First Vice-President, Dr. W. S. Stewart, in the chair.

Dr. Joseph Hoffman presented a paper on "The Questions and Lessons of Ectopic Pregnancy."

The doctor argued that electricity and the injection of lethal substances into the sac have no place in the treatment of this alarming condition and that surgical interference is the only rational mode of dealing with it. It should be treated as all other disease is treated which involves the presence of a foreign body—remove the offending portion, the earlier the better, before complications are present, and before the growth is dangerous by its invasion of other structures. As to the let alone doctrine of Freund, and those who say with him that ectopic pregnancy is a disease that very frequently cures itself: It is not worth while to dispute this. The same may be said of almost every disease, surgical or medical. The argument applied to the affairs of a business world would be received with ridicule—they are no less ridiculous in surgery. The surgical, practical and sensible view in which to consider ectopic gestation is to cut it short as early as may be, unless the child is viable. In the latter case the treatment which is most rational is that which would save the mother.

Experience has demonstrated that rupture may recur and its recurrence kille hence to say that rupture is not always fatal, is to agree to what we all know. What we all further know is that after on; rupture, the second or third may be fatal, and that is sufficient argument not to wait for a second or indeed to wait at all. In the direct treatment of this disease we have only one indication to meet, and that is the stoppage of hæmorrhage.

The essentials of the question under consideration are; its frequent fatality not its possible benignancy, and the absolute simplicity of its treatment when early undertaken by real surgery and surgeons; its curability even when the patient is in extremis; the complications and dangers of delay in those cases that get well without interference, and the uncertainty whether or not interference may at last be not necessary. These are the essential questions and they have their answer in the axioms of positive surgery, not in the calculation of chances.

DISCUSSION.

Dr. G. Betton Massey said that he did not know how many cases of extra-uterine pregnancy he had treated by electricity as he had not taken the trouble to operate to establish the diagnosis, but he had been able to diagnose with reasonable certainty three cases so treated. The use of this conservative agent is confined to very early discoveries of extra-uterine pregnancy prior to rupture, and those cases he believed could be invariably cured by it prior to the third or fourth month.

Dr. Joseph Price believed that primarily all these cases are tubal, that they rupture; and few, if any, ever go to four months or even three months without rupture. He has never seen one or known of one. There has been nothing in his surgical experience to correspond with that of Mr. Tait or Hart and Barbour, except that with Mr. Tait, he believed that they are all tubal and all rupture; but the remainder of his experience that they go into the broad ligament and go on to term, he is not willing to accept for a moment.

Dr. Massey speaks of the use of electricity at the third or fourth month. In all the cases that Dr. Price has seen, rupture has taken place long before the third month. If Dr. Massey will read Dr. Formad's experience, he will see that in thirty-five fatal cases, none was beyond the third month. Some had gone a week over time and some two weeks and all had died suddenly, except one in West Philadelphia. There was a chance of saving one out of thirty-five.

We still hear something about so-called pelvic hæmatocele. Those cases of so-called pelvic hæmatocele present precisely the same history as the cases we are constantly operating on for tubal pregnancy and finding the fœtus and quantities of blood, and removing the fœtal sac with a great hole in it.

Dr. Joseph Hoffman said he had hoped that the phase of the treatment of the child after viability or of allowing it to go on to viability would have received at-

tention. He did not believe in it, if by any means we can discover the pregnancy early. He would as soon think of allowing a tumor to grow in a woman's breast to see whether it was going to turn out malignant or benign before removing it, as to allow ectopic pregnancy to go on if he found it early. The point in reference to electricity in these cases is the diagnosis. Dr. Price has opened many abdomens expecting to find ectopic pregnancy but did not find it even after the symptoms of rupture. Even after the stoppage of the menstrual flow for some months, the presence of a large mass to one side, hæmorrhage, apparent discharge of membranes, the diagnosis can not be made positively. He questioned the ability to make a diagnosis because so often a mistake is made even when the abdomen is opened. The question of removing these masses in the early months is one that we deal with positively from a surgical standpoint. That is the safe time. The effect of electricity, it must be confessed is problematical. The current used is the Faradic, which has little or no electrolytic power. Why such a current will cause the fœtus to be dissolved or absorbed, is a question. Again, it must be remembered that the length of time required to destroy the fœtus is usually the time during which rupture occurs. The stimulation of the galvanic current may rupture the sac.

Dr. Joseph Price read a paper on "Ventral Hernia Following Abdominal Section." The subject, he said, is one of more than usual interest to the profession. It may be laid down as an axiom that these cases require skill and promptitude in dealing with them. They are not cases for experimentation—the apprentice has no business with them. In them, very little bungling will kill. Careful, expert surgery saves about all. The predisposing causes are: 1st. Too rapid, hasty and imperfect preparation of the patient for section. The bowels should be thoroughly evacuated and accumulated fecal matter freely discharged. Rapidity in operating is of vital importance; minimizing the quantity of ether—the exciting cause of persistent nausea which puts a constant and trying strain upon the healing incision. 2nd. Neglected or delayed operations in cases of emaciated and greatly exhausted patients. Those requiring heroic operations are most unfavorable without careful preparation and they are of the class where there is no time for preparation. They are difficult subjects for recovery, healthy union, consolidation and organization in the incision. Well placed dry dressing and a comfortably tight bandage on a dry wound will give about perfect results. Wounds uniting by first intention throughout, are rarely followed by hernia. Stitches placed too tight and too far apart should be avoided as favoring stitch hole suppuration. Multiple suturing of incision with imperfect material strongly predisposes te hernia. Nausea, too early feeding, restlessness and too much latitude to nurse and patient are also predisposing causes. Scrupulous cleanliness and the avoidance of irritating solutions are of paramount importance in all surgery, general and abdominal. There should always be the shortest possible incision, and least possible manipulation. But one set of hands—those clean—in contact with the wound. A thorough use of the douche and well placed small glass drain, vertical, never oblique, followed by perfect co-aptation of all divided structures by not less than three sutures to the inch.

The closing of a ventral hernia is interesting and instructive. It is not a simple operation but an important surgical procedure. The opening or removal of the sac is complicated by bowel and omental adhesions—all sequelæ of an imperfect operation. Many of these secondary operations are done for two purposes; 1st to cure the hernia, 2nd to free all adhesions—to relieve the patient from the pain due to anchored viscera and the risks of bowel obstruction, not uncommon in the presence of such adhesions.

DISCUSSION.

Dr. Charles P. Noble agreed with Dr. Price in regard to preparation for operation. He keeps the patient on her back for two weeks after the operation and thinks the practice of allowing her to roll about is a bad one; in the first place because the patient is more uncomfortable, and in the second place because the movement favors hernia. He did not agree with Dr. Price as to the method of suturing. Instead of passing the sutures

entirely through, he pushes the skin with the underlying connective tissue back and inserts the needle in the aponeurosis and passes it through the recti muscles and peritoneum. When tied it is a buried suture. In an incision two inches in length there would be five or six buried silk-worm gut sutures. By this method of suturing you can see that the edges of the aponeurosis are brought together, which makes stronger union. Like Dr. Price he had not been favorable to catgut and uses it but little. The longer patients stay in bed the better. He followed the rule of allowing them to get up in three weeks and thought, with the buried suture, that that was long enough.

In regard to operations upon hernia, the operation described by Dr. Price is undoubtedly a good one, otherwise it would not have given the good results that it has done. He thought the peritoneum should be divided and dissected loose from the muscles, the entire face of the muscles should be made raw, the edge of the aponeurosis dissected out for the length of the incision and the skin freed from the aponeuroses. The sac must be dissected out as Dr. Price described and the intraperitoneal treatment must be followed out as he directed. Having done that, he thought that it is better to sew up the peritoneum with a running catgut suture and put buried sutures of silk-worm gut through the aponeurosis of the recti.

Dr. G. Betton Massey said that this discussion emphasizes what he had so frequently said, that physicians should carefully consider the question of abdominal section, instead of entering into it blindly. Again, he would ask why Dr. Price does not apply the same methods to the original operation that are so successful in preventing the recurrence of the hernia.

Dr. John S. Miller had done this operation twice. After opening the abdomen, he felt for the margin of the recti muscles. After dissecting out the peritoneum, he incised the edge of the rectus muscle and threw the sheath back and did the same on the other side. All the through and through sutures were then inserted, and while an assistant brought the parts together, he stitched the peritoneum with a continuous catgut suture. Then with interrupted sutures of catgut, he brought together the two muscles, taking in the posterior sheath. The wound was then closed. So far the result has been good.

Dr. Joseph Hoffman said that if silk-worm gut can be left in permanently in an incision, and with any advantage, he did not see why we should not leave silver wire—the one is just as unabsorbable as the other. In several instances he had seen silk-worm gut accidently left in, but it has always a foreign body, not causing suppuration, but working its way out, as a tack or a pin or a bullet might do. He did not criticise the method described, but only questioned the advisability of leaving a number of sutures under the skin with knots like those of silk-worm gut. They become hard and unyielding and how they can remain under the skin without producing discomfort is a question to him.

In regard to the location of the incision, it has always seemed to him, apart from the matter of convenience, that those incisions where we have to go outside of the linea alba into the muscle, have been less likely to lead to hernia. When such an incision is closed, we have not simply fascia or aponeurosis, which do not unite very readily, making the union, but muscle itself; so that he was not sure but what cutting to one side, into the muscle itself, may not be the reason why hernia does not occur when the abdomen is closed carefully.

So far as the occurrence of hernia is concerned, it must happen in the practice of all, especially if patients are allowed to get up too soon, and especially, he believed, in fat women, for in fat women you have large quantities of omentum which gravitates into this region and the fat of women seems to be opposed to muscular tension. While he had no doubt that many will question the truth of this proposition, he thought the truth remains that in slender women we are less apt to have hernia than in the obese.

Dr. George I. McKelway did not think that Dr. Hoffman's comparison of a silk-worm gut suture, anchored to the aponeurosis, to a pin or a bullet is a fair one. In the one case the material is anchored, while in the other it is loose and the motion of the individual moves it so it sets up irritation and finds its way to the surface. As to the suggestion of cutting through the muscle, if we thought for a moment we should remember that the fibres of the recti muscles run in the wrong

direction for us to have any added strength from an incision made in the line of the muscular fibres. We all know how easy it is, after reaching the muscle, to separate the fibres with the finger or the handle of the scalpel. There seems to be little cohesion. He did not see how their healing will result in stronger union than before.

Dr. Joseph Price said that the observations of the older ovariotomists verify the point made by Dr. Hoffman that no harm comes from splitting the recti muscles, and a number have gone on record with the observation that it does no harm and that union is usually stronger and better. Dr. Price aims at the white line but has repeatedly noticed that, where he has taken the opposite side and cut through the muscle, that no mischief has come and union is always complete, solid and perfect. These buried sutures do but little good, once the incision has united. They are loose in their entire circuit and do not act as splints. They will behave badly in time. Not only will cases come back with suture abscesses and not only will it be important to remove the sutures, but hernia will occur as often, in these cases, as where the sutures are removed.

Dr. Miller's operation is a perfect one but it takes too much time. The through and through suture will do the same thing as the terraced suture. The approximation is just as perfect. The overlapping and dove-tailing of aponeurosis is valuable. No harm comes of it. Aiming at a perfect coaptation of these two thin lines of divided aponeurosis is folly and avails nothing. He would rather have them overlap an inch than to be just in juxtaposition. Rest on the back is of vital importance. It is comfortable to the operator and also to the nurse as well as the patient. If you roll the patient as counselled by Greg Smith, and others, and allow her a little liberty, she will give you and the nurse great annoyance and anxiety.

Dr. Horace Fox presented a paper on "Some Obstetrical Experiences in the 'Slums.'"

The doctor stated that the most troublesome patients he had to deal with are the Russian Jews and it requires about twice or thrice as much work to bring such a case to a successful termination as any other class he has had occasion to treat. During his three years of service in connection with the Philadelphia Dispensary he had attended some hundreds of obstetrical cases, included septicæmia [infected before he took charge], eclampsia, peritonitis, hydatiform mole of uterus, erysipelas, and other affections, complicating the puerperal state, besides having used the forceps, performed version and craniotomy. The results have been good, he having lost but three cases. The first was a case of eclampsia of nephritic origin in her second pregnancy, having had almost fatal eclampsia in her previous confinement ten years before. The second was a case of pleuro-pneumonia in which he was not called to see the patient until she was moribund. The third was a case of heat exhaustion, occurring within eighteen hours after delivery and caused by excessive beer drinking.

The septicæmia cases can be saved by untiring attention to the patient even in surroundings which are filthy and totally unhygienic. The cause in two cases was decomposition of retained portions of the placenta; in the other, criminal negligence on the part of the graduate in attendance since he had not even washed his hands with soap and water. One case of eclampsia was epileptiform in character, the patient having had fits ever since she could remember. The doctor attended her in her third confinement and learned that she had had a convulsion in her first labor but none in the second. The fit occurred in the second stage, when the head was low down in the inferior strait and close to the perineum. The forceps were applied immediately on the stoppage of the convulsion. No other fit occurred during his attendance. The hydatiform mole is of comparatively rare occurrence.

The doctor stated that he met about a hundred physicians and students yearly in connection with his work and he is surprised at the lack of the fundimental principles of obstetrics that they manifest. He would urge necessity of earlier and better training and that the student be given more plain theoretical and practical work in obstetrics. Let him be more thoroughly quizzed, not only in the theory, but also in the practical work. Let him be disciplined in detecting, on the manikin, presentation and positions as they commonly occur, and urged to read and study

good standand works and not compends, etc.

DISCUSSION.

Dr. Joseph Price said that there had never been a premium upon skilled obstetrics. At one time it was done by vulgar, ignorant midwives and, in this city, out of 20,000 labors, 5,000 are reported by midwives. There are from 120 to 130 midwives practicing in this city. No woman should be attended by a midwife unless she bears a diploma from a good midwifery school where the theoretical and practical training is carried out as in Germany. We have no such school in this country. We have all felt the importance of early teaching and practical training of the student for practical work. Obstetrical instruction, unfortunately, begins with the second year and in some schools the student, for examination purposes, shirks obstetrics even in the second term, hoping to pass on every thing else, and thinking that he will have ample time to make it up in the last year. So much is this the case that Dr. Price thought that obstetrics ought to be taught during the first and second years, as this is one of the branches in which early practice can be had. More than half of the students do not own a classical work on obstetrics; they are living on compends and notes.

Dr. William S. Stewart presented a case of twin pregnancy of unusual interest.

Superfœtation in a bifid uterus was the anomaly he had the honor of reporting to the society. The patient was a primipara presenting no special symptoms during gestation. At the preliminary examination only one heart sound was audible. She was delivered after a long and difficult abor of an enormous child. On examining the abdomen with the intention of removing the placenta a hard resisting body was found in the right upper corner of the uterus which proved to be another, undeveloped, fœtus. The membranes were ruptured and the fœtus delivered. It proved to be an immature living fœtus of from six to seven months gestation. The child is still alive, nearly two months old.

DISCUSSION.

Dr. Joseph Price has seen several cases though not exactly like the one reported. In one case the woman was delivered of three children, the last quite macerated and dead for at least a month. Dr. Price afterwards got the history of a fall down stairs at the eighth month with quite free bleeding, and thought the child was killed at that time.

Dr. W. S. Stewart regretted that he ruptured the partition and did not let the second child go to full term. The lesson to be learned is not to be in a hurry to deliver where you find that the placenta is separate and the child is occupying a separate compartment of the uterus.

Elliston J. Morris, M. D.
Secretary.

MEDICO-CHIRURGICAL SOCIETY, OF LOUISVILLE.

Stated Meeting of October 14th, 1892.

Dr. F. C Simpson, President, in the Chair.

Dr. C. Skinner: I exhibit here a leg removed from a man seventy-two years of age, because of sarcoma. The man gives the history of having a fall during the month of February, 1892, spraining his knee. You will notice I made an incision just above the knee and a great quantity of very soft, friable tissue was removed. From the appearance at first it seemed to be a typical case of osteo-sarcoma, but the bone proved not to have been involved. Of course had it been osteo-sarcoma, the leg would have been removed at the hip, but as it was simple sarcoma, I amputated just above the middle third of the thigh. The man reacted well, pulse went down to about 40, but in an hour or so he had rallied and the pulse went up to 100. There was very little hæmorrhage during the operation except by oozing. This growth was first noticed in July last, and has developed very rapidly since; at the time of operation the tumor was enormous. The man has had no fever nor pain, excepting some slight shooting pains from the growth within the last few days. Operation done this morning at ten o'clock; he was doing well this afternoon.

Dr. T. S. Bullock: I have nothing to say concerning the case, except that the man had a very bad heart, irregular pulse and took chloroform rather badly. When Dr. Skinner first cut into the swelling,

there was such a gush of blood that I thought he had gotten into an aneurism sack. After the tourniquet was removed the oozing increased and for this reason the man was kept upon the table longer than he would have been under other circumstances. At one time I feared we would not get him off the table alive; he became pulseless at the wrist, but by elevating the foot of the table and giving a hypodermatic injection of ether and another of whisky, and using some nitrite of amyl he reacted very nicely.

Dr. J. W. Irwin: I think the operation is a very judicious one, and where it was done makes it about as safe as anything of the kind could be. I am inclined to the opinion that the man will live some time before he has a recurrence of this trouble.

Dr. W. L. Rodman. The case so far as I know is rather unusual. Sarcoma is apt to occur more frequently in the first half of life rather than in the last half. It is rather uncommon in a man seventy-two years of age, especially in this location. In my experience, I have only seen one sarcoma of the soft parts, and that was in the thigh of a man fifty-five years of age. Osteo-sarcoma occurs most frequently in patients from twenty-eight to thirty-two years of age. Of course they occasionally occur in older subjects, but the average is between the ages of twenty-eight to thirty-two. I would like to ask Dr. Skinner what variety of sarcoma this is.

Dr. C. Skinner: No microscopical examination has yet been made.

Dr. W. L. Rodman: I have here two specimens, one of which I showed a few evenings ago at a meeting of the Surgical Society. It is a small, imperfectly developed, retained testicle, removed from a young man twenty-six years of age, who is large and well developed, weighing 180 to 190 pounds, and yet he had this very small imperfect testicle. He was ruptured on the right side and had been wearing for six or seven years a double truss. This truss on the right side probably subjected the testicle to a great deal of pressure, as it was situated just to the left of the external abdominal ring. This may account for the cystic change in the testicle. The cord was very short and would not allow the testicle to be brought down into the scrotum, even if it had been a perfect organ. I believe that the majority of incarcerated testicles are imperfect organs, and functionally inactive, and the best thing to do is to remove them. However, when they are in the abdominal cavity, they may be functionally active, and their removal would not then be advisable. This operation was done about a week ago and the dressings were changed for the first time to-day. The wound was closed by continued buried sutures; the patient's temperature never went above normal; pulse never below 60, and there has not been a drop of pus.

No. 2.—This specimen is a penis removed from a man about seventy-three years of age, giving a history that nearly twenty months ago he noticed a small wart on the glans penis. The man was a patient of Dr. Peyton's, and I saw him for the first time in consultation two days ago and advised early amputation of the penis, which was done yesterday. You will notice quite a large wart right under the glans which was as hard as a rock when it was removed. There were also enlarged glands in either inguinal region, which were carefully dissected out. The penis was entirely covered by a flap of skin; it looks very much like the natural organ, except, of course, it is very short. I would like to ask Dr. Palmer if he would have advised amputation in spite of the fact that the man had excessively enlarged glands on both sides.

Dr. E. R. Palmer: A gentleman asked me to-day in my office if I had ever amputated a penis, and I said no. I suppose my experience is peculiar in that respect. A patient was brought to me some years ago by Dr. Dowry, of Shelbyville, suffering from cancer of the penis—at least that was the diagnosis. I could not see that it was cancerous at all. and disappointed the doctor as well as the patient by not amputating the organ. I am ready to confess that I have had no experience in the matter of cancer of the penis, or amputation of the organ.

Dr. C. Skinner: When did the glands begin to enlarge in the groin?

Dr. W. L. Rodman: It has been four or five months since he first noticed the enlargement; they have been growing very slowly.

Dr. C. Skinner: I think amputation of the organ entirely justifiable.

Dr. W. L. Rodman: I will simply state in closing that I thought possibly

there might be some criticism on the operation being done. I have seen one case in which there were excellent results following amputation of the penis, and there has been no recurrence of the growth notwithstanding the fact in that case as in this, the enlarged inguinal glands were on the left side. Operation was done eighteen months ago, and there has been no rucurrence.

Dr. J. W. Irwin read a paper on "A Cause of Prostatitis." (see page 806.)

DISCUSSION.

Dr. T. S. Bullock: I have heard some talk about urethritis and prostatitis resulting from bicycle riding, but I have never seen such a case myself.

Dr. E. R. Palmer: Within the next two or three years I believe we will see a great deal in the medical journals, editorial and otherwise, in reference to the effects of bicycle riding upen the sexual apparatus and sexual powers. Given a man with absolutely sound sexual organs, I can imagine that he might possibly withstand the injurious effects of bicycle riding. At the last meeting of State (Kentucky) Society, I cited three cases of prostatic trouble that I could not account for, except by referring to previous damage on one hand, and to the immediate injury of bicycle riding on the other. In that paper I made the statement that albuminuria as a cause for rejection for life insurance, was partly referable in these cases of bicycle riding. I believe that any man who has had an attack of gonorrhœa extending over a period of three or four months, with prostatic infection, the prostatic sinuses being involved, and then gets well, endangers himself by riding a bicycle. A gentleman weighing probably two hundred and thirty pounds consulted me within the last ten days, complaining of a peculiar burning sensation during the act of micturition, with also a slight discharge from the urethra, which I think was directly referable to bicycle riding, and this is only one of a number of cases of the same character that I have seen.

I think much of this trouble could be avoided if the bicycle saddles were properly made so as to relieve the pressure upon the prostate. They should be wider with a wider gap or slit in the middle. As you probably have observed, there has recently been a marked improvement in this direction.

Dr. C. Skinner: I think a great deal depends upon knowing how to ride a wheel. In my opinion these prostatic troubles will either be found to be old prostatic troubles re-excited, or else the riders are beginners. I would like to ask Dr. Irwin if he has any history as to the length of time these men had ridden the bicycle before they came to him as patients.

I do not see why, with the seat properly adjusted, there should be any pressure upon the prostate.

Dr. T. S. Bullock: I believe that Dr, Skinner is correct, if the saddle is properly pitched, we will not have any trouble; I do not deny that trouble will occur if the saddle is improperly placed.

Dr. H. A. Cottell: I am glad to see this subject brought before a Medical Society for discussion. We have heard for several years that bicycle riding produced albuminuria, but I have never seen anything like statistics or proof on the subject. However, I have been forcibly remainded of the fact by my experience recently. I have examined a great many young men for life insurance and have found a small amount of albumen in the urine, which could be attributable to no other cause than bicycle riding. I will mention one case in particular: A young man about twenty-five years of age came to me eight weeks ago to be examined for insurance; he went through with a perfectly straight record as to everything, but upon examination of his urine I was very much surprised to find as much as one-quarter per cent of albumen. I held this man up, did not immediately reject him and have kept him under observation since then, examining his urine from time to time. The quantity of albumen has diminished, but can still be detected by careful test. He is a great bicycle rider.

In the paper and remarks thus far albuminuria has been attributed to prostatic irritation, inflammation, or a re-lighting of an old prostatitis following gonorrhœa in many cases—I believe that we may perhaps find bicycle riding will account for it all. It would take a very considerable prostatitis to give one-fourth per cent albumen in the urine; there would have to be a very decided inflammation to produce that quantity of albumen.

Dr. J. W. Irwin: In answer to Dr.

Skinner as to the length of time my patients had been riding; two were beginners, and three had ridden for about a year. I do not intend to discuss the question of albuminuria in connection with the paper, but simply the question of "Prostatitis" and "Urethritis" as a result of riding the bicycle. I cannot see the difference whether a man has or has not had gonorrhœa in the extent of injury or trauma produced by the saddle of the bicycle. If a man has a damaged organ, certainly he would be more liable to suffer from pressure of the saddle than he would otherwise. Two of the cases I reported (the history of which I did not give in detail) were men who had gonorrhœa fifteen years ago; one of them had had gonorrhœa which lasted nine months, the other lasted seven or eight weeks; they assured me that they had no other attacks. The other two cases assured me that they never had had gonorrhœa. The fifth case, a young man eighteen years of age, had gonorrhœa of very recent origin, which lasted him only a very short time, and from which he was entirely cured as far as he knew. He had been riding the bicycle four weeks before he came to my notice suffering from this form of prostatitis or prostatic urethritis, accompanied by a slight colorless discharge. So far as the shape of the saddle of the bicycle is concerned—I do not see how that concerns us now; what we want to ascertain is the effect the saddles have on these parts, the remedy will be considered later. I do not know of anything that could be more likely to prove injurious to the prostate than the chafing and pressure from the bicycle saddle. In my experience extending over twenty years, I have never seen a man who had had prostatitis get entirely well; he will always have a tender prostate gland.

I think the subject is one of much importance, and I feel this more now since the discussion than when I prepared the paper presented.

Stenographically reported by C. C. MAPES.

IN Michigan they assess a dog $1 for being a dog. In Tennessee they assess a man fifty cents for being a doctor. It costs half a dollar more to be a dog in Michigan than a doctor in Tennessee. Don't be a dog.—*Battle Creek Moon.*

Correspondence.

AN EDUCATIONAL NEED.

II

Editor of MEDICAL AND SURGICAL REPORTER:—We are always breaking away from the old and seeking after something new—it is of our temper, a human impulse of impossible resistance. Yet we are not so ungrateful or irreverent as to ignore our heritage from noble ancestors whose wise endeavors have made our civilization all it is—something in which we have a well founded pride. Everywhere are the evidences of what the genius, patient toil and intelligent gardening of the past have done for us. We have no laugh for the circumstances under which our fathers lived—they laid for us the foundations of our better conditions—their sacrifices have made our victories possible. We can move on without desecrating their landmarks. We cannot remain satisfied with being simply legatees. We will not be laying ourselves open to the imputation of presumption or insolence if we say all we have is so much of grand material with which to work and build. Possibly the best lesson our ancestors have transmitted to us is the one that they were not idlers, but men with definite aims and great ambitions. They did not gain their results through some easy mechanical process, but by toil. Our aim may be somewhat ideal. It is the supremacy of our educational system over that of every other of our country, even over that of other countries—and this for the most potent of reasons, that it is our educational systems that give direction to the genius, talent and enterprise of our country; that mitigate and make more prosperous and hopeful human conditions. It would certainly be unwise to discourage the somewhat feverish desire and creditable impulse and eagerness of our community to lead in the excellence of our educational institutions. General public sentiment has much to do with the building up of the aims, character, conduct and practical working of our institutions. This sentiment is a matter of education. Popular interest is an outgrowth of popular need. A very important question is, do our schools of medicine and surgery fully answer many practical and acknowledged needs ?

Our medical colleges have always had the prestige of great names. Identified with them have been great teachers, men eminent in science and letters, matched to every responsibility of their exacting profession. This prestige must be sustained. Our institutions of the old East will have to struggle to keep pace with those of the new and enterprising West. All our advances will largely lie with the teachers in our colleges. And the first duty of the teacher is to advance the institution with which he is associated. This can best be done through scholarly scientific attainments, by grappling with the many problems acute minds have left unsolved. The men engaged in this work are devoted to the highest of human pursuits; investigating and stimulating investigation seeking for the valuable mysteries a searching Science alone can unfold for us. The very term "professor" has a marked significance. It implies learning, scholarship, manliness, a genuine dignity, unselfish devotion, a worthy jealously of individual repute, an ambition to advance academic education in quality and quantity; it makes lustrous the name of the college to which he belongs, in which he bears the most honorable and high of all commissions. Where the appellation, professor, is officially applied it should be seen to that all is represented that the term implies. Where all the dignity and high qualities of the title are impersonated, only from the vulgar will pass the rather irreverent greeting, "How are you, Jake?"

Our colleges are well equipped for good work,—eminent teachers with all the aptitudes of their calling, with every needed resource at command, large libraries, museums and laboratories with all modern appliances. To many of them the State has not been niggardly in its munificence. And they have not been overlooked in the matter of endowments.

There can be no objection to endowments.

They are essential to the adequate equipment of schools and colleges, for the supply of the most modern and improved apparatus for the teaching of the sciences and for making the very best every condition within their walls. And they serve a beneficient purpose in relieving many of a burden they cannot carry with them "over the Styx." They can be made to serve in improving environments. One of nature's methods ofdevelopment is through environment–men are trained by their surroundings and they should be the best that money, skill, labor and time can make them

Liberal, good-living salaries should be paid to teachers, from the teachers in our common schools to the highest professor in our colleges. They are not out in the manufacturing and commercial world making fortunes, but devoting time, culture, talent, energy and vitality, all that is best of their lives tothe advancement of science; all that betters, makes more healthful and happy human conditions. Salaries, however large, fall short of the full measurement of their service.

Society cannot overrate its debt to its teachers, it can only in part recognize and pay it by measurably reducing their labor, by furnishing them with every facility that will promote easy and successful service. The fact should be taken home that the tone of private and public morals goes out from their desks. The better-thinking public may have a taste for the humor that plays on high moral grounds, but have none for the low, gross jest, nor has it other than aversion for any one in the high calling of teacher or professor who utters that which does violence to moral sentiment. It will probably require a dozen or more milleniums to pass before some few,—luckily they are very few,—will reach a complete understanding of this fact.

Yet withal it isnot so much a pecuniary or property endowment that promotes the real wealth of the school or college as it is high educational aims, pure scientific teaching, having about school and college a clean, clear, moral and intellectual atmosphere. A devoted, tireless spirit of investigation and research constitute the genius of the successful college.

In my communication in your issue of the 29th ult., I endeavored to give a few practical suggestions bearing upon at least one of our needs. I may have been somewhat vague and indefinite, yet I hope I made myself sufficiently plain for the intelligent reader to get hold of my meaning. My suggestions as to hospital uses and the establishment of open and free clinics should recommend themselves as of a practical character. When general practitioners old and young, are coming to us from every section of the country for what our

schools and hospitals, physicians and surgeons can teach them, the question is raised, what method can best be adopted to serve their high purpose? Many of these men were educated in our own colleges and should by them be kept well armed, and directed along the advancing lines of the profession. Their names may not appear on a Philadelphia chart of pedigree but they carry a stalwart American manhood under their hats that settles upon them the title of the proudest peerages. They are not of "The royal lineage of our noble and gentle families," but are humble men without any ambition to date their ancestry back of that very conservative, easy-going old gentleman gardener, Adam.

They are a little ahead of those who, with something of an air of insolence claim to know more,—indeed to know it all. They realize the vastness of the things they do not know. There are things about which they have a sound sense of ignorance and they are zealous and patient in their endeavors to widen the fields of their science and general knowledge. They realize that their greater success is limited only by lack of knowledge of what to do, and when and how to do it. They are men eminently capable of intelligent appreciation of good work; they would improve their own methods of practice by the best evolved by pure science or by clinical study, research and result. They would widen the range of their general knowledge and equip themselves with modern weapons with which to grapple with modern conditions. All this from their love of and interest in their profession and for the better service of humanity. They worthily seek honorable eminence in their profession, local or general. It is true that it does not lie within the powers of any institution or within the possibility of any form of democracy to make all men equal, any more than it does to make all men's feet of the same size, or to reduce to a modest standard some men's egotism. But among our possibilities is that of making every man better, morally and intellectually; to better fit him for his work, offer him the instruments wherewith he can do it well. We have all the instruments, all the agencies and facilities for this work about the tables of our clinics and within our hospital walls. The oversensitiveness of the lay authorities of our hospitals to the clinical, the bedside use of patients, in the study and development of a growing science in which is wrapped up human weal, will give way before the nearing light of a new century. Hospitals should be added to and made part of the machinery of medical education. In them should be organized a system of clinical teaching in all lines, special and general and specialists should not be excluded from their staffs, as they are, under the pretext and sham of economy.

We hear of no objection offered in our private special hospitals to the presence of visiting practitioners and their profiting by the clinical use of cases; if there are any exceptions to this rule, they are as rare as they are discreditable. And the fact should be considered that the patients in these private hospitals usually pay their own way, while those in the public ones are the beneficiaries of public or private charity. We are not advocating any abuse of human decency—the exercise of arbitrary power over those who by the misfortunes of accident or disease are brought to the beds of our hospitals, but we are endeavoring to break down an unreasoning and unreasonable prejudice. The popular prejudice against such use will disappear with its adoption. Certainly there should be something reciprocal in this matter—a recognized debt due from those whose needs and sufferings communities care for—Christian charity ministers to. This debt can best be paid to those co-ordinate workers, Medical Science and Surgery, whose noble mission is to mitigate human suffering, prolong human life, and restore that strength to man and woman which will make happier their conditions enable them to work longer and better, and fill out their lives with usefulness.

Yours truly,

JOSEPH PRICE, M. D.

Preston Retreat.

Doctor, said the dying editor, I have one last favor to ask of you.

Name it, said the doctor.

I want you to attend the editor of the other paper!

HE FORGOT SOMETHING.—*Doctor*—I will leave you this medicine to take after each meal.

Mike—And will yez be koind enough to lave the meal, too, dochtor?—*Tid-Bits.*

THE

Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS:

Care P. O. Box 843, Philadelphia

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY NOVEMBER 19TH, 1862.

MAKING REPAIRS.

There are some practical suggestions in an excellent paper by Dr. Luther B. Grandy, of Atlanta, Ga., read before the Tri-State Medical Society of Georgia, Alabama and Tennessee, an analysis of which is given in the *Virginia Medical Monthly*. Without attempt at review we call the author's statements and pertinent criticism to the attention of the profession as worthy of thoughtful consideration. We regard them as having more than a local application. He gives the testimony of an eminent physician which is not without its application to our time and systems of medical education. Referring to the earlier systems he says they "now look back upon their medical college career as an unimportant epoch, and think of those days as a work of confusion. The instruction afforded by this system of medical education was hurried, superficial, and most inadequate to our wants, the course consisting rather in calling the attention of the student to the *art* of medicine, instead of teaching him the *sound principles* upon which is governed the great field of active practice." Again he says, "I attended the prescribed two courses of lectures in a medical college; each course lasted about five months, and was precisely the same. There was no laboratory course, and I began to attend clinical lectures the first day of the first course. One result of this, was that I had to learn chemical manipulation, the practical use of the microscope, etc, at a later period when it was much more difficult; in fact, I may say, that I have been studying ever since to repair the deficiencies in my medicial training, and have never been able to catch up." When our old, able, cultured and honored men, men whose professional lives are crowded full of the lessons of rich, varied and great experiences, tell us that they have been studying to repair the deficiencies in their medical training and have never been able to catch up, hooves us to look with very keen scrutiny for the defects in our existing systems. We never get out of school, but we do not want to have to go back to our primers in our old age,—to waste practical years in unlearning the lessons learned preparatory to our work. The hints of these men are invaluable. They direct us into better ways and teach the possibility of better things; they drive out many old conceits; they infuse into the profession a spirit that will ultimately crowd to the wall all coxcombs, charlatans and quacks, and give us something better than mere book-read and theory-stuffed men. It is true that time has taught the inefficiency of many old methods, and it is true that our methods will go on improving as science and better teaching continue revealing their incompleteness and adjusting

newly discovered principles to better understood facts and conditions of life. Our older institutions are historical in their growth; in spirit and effort they have kept step with ever changing conditions; they have not permitted modern demands far exceed their grasp.

Our old teachers cherished some delusions we do not, we cherish some they do not. Medicine has not reached the point of an exact science, and never will, but our advances in scientific knowledge will be steady and certain, and general practice will share in these advances. There is something of tremendous energy, of heroic temper in the efforts of our generation to advance the standard of education, both along professional and general lines. There is a current faith that while our educational systems serve a high purpose, it is within the possibilities for them to yet more efficiently serve a yet higher purpose; that while they are good they can be made better. The best method may be superseded by a better, the antiquated by the more modern, plain and simple. The modern educated physician and surgeon is inspired by a new pride in his profession, he feels the augmentation of his resources, he is drawing more and more freely from the exhaustless mines of pure science, and less and less from ancient mythology. He is leading a life of performance, proved not so much in his inheritance or special gifts, as in his attainments; he has, as a motive, something nobler than the rapid accumulation of wealth.

The chief stimulus and encouragement of the physician lies in the high aims and tendencies of the profession; in the manhood attracted to it, in the innate moral worth and high culture of its personnel, in the enlargement of the idea as to what constitutes medical education and makes up the highest and best professional character.

The weight carried by the profession, by which it is most burdened and which most retards its advances is made up of the men who will not break away from old traditions, who "have died before they expired," but from whom all ambition to move on, for work and growth, has passed; the ones who, satisfied with old and imperfect results, have no care for better ones; men who are contented with their little bundle of dusty experiences and deny the existence of better ones. Nothing would be so agonizing to these men as the puncture of their shams. Equally heavy to carry are those imponderable individuals the little cherubs who are complacently waiting the coming of their wings. Their diplomas procured, the measure of their ambition is filled out, and with them life is only a *waiting* from the date of their diplomas to the date of their funeral certificates. To this class such a thing as study, investigation, even thought—would be painful. Infinitely little units forming in the aggregate a massive burden.

Better material, more brains, and higher purpose would be introduced into the profession by broadening educational requirements for entrance into the medical college, by extending the terms of study and by making more rigid the examinations before granting certificates of graduation. Such a practice would not tend to deprive the farms and workshop of laborers, nor to deplete the ranks of shoemakers. In nearly all the mechanical trades an apprenticeship of from two to four years is required, years with fifty-two working weeks in them and with days of ten working hours, all this, perchance, to learn how to make or to repair a wagon. Yet we require an apprenticeship of only two or three years of five or six months each for the student of medicine to make himself familiar with all the minute parts of our complex human economy; with the inherent and essential laws of man's physical make up. Brief time in which to master the rudimentary elements of a science infinite in its reachings—a science

that involves spirit, mind and body in their inter-relations. Is this not rather turning loose a lot of experimenters to ply a trade on the ignorant and unfortunate. The army and naval authorities set a good example in this matter, the medical and surgical appointees in these branches of the public service are subjected to the most searching of examinations in every branch and detail of medical and surgical science, and only those pass muster who meet the rigid requirements. Dr. Towler says sixty-eight per cent. of the applicants fail to pass. And with these authorities it is not enough for a man to be filled with information, he must have the art to make its application to practical uses. He must be something more than a mere medical encyclopedia.

Too many enter the profession on a calculation of profits on a minimum amount of labor—the grave responsibilities are of secondary consideration. We need to have a very high ideal, and severely measure our actual by it. The physician should be greater than his profession—in him and not in his calling should be the elements of predominance. He must within himself be a master if he would be a master in his work. There is no profession, not even that associated with the science and art of war, in which every element of the heroic so largely enters.

The physician is representative of the very best interests of his community, moral, social, intellectual and physical. Knowledge of human physical disorders, is but part of the knowledge he should possess. There are moral and social disorders of which the physical are often the outgrowth—so one knows this fact better than the physician. He carries the secrets of half the families in the community in which he practices; knows something of the skeletons in their closets—has it in his power to destroy domestic happiness at the bidding of avarice, malice, or revenge for some real or imaginary wrong. Usually he is the practical humanitarian in the community in which his work locates him. And no class of men exercise as great an influence in breaking down the partitions of caste, and liberalizing social tendencies. The conscientious physician's life, from the time he passes without the college walls, is one of brave service and sacrifice. His life must be persevering, unselfish and generous, or he clouds his name and dwarfs his influence. He must have the nerve to move with an unwavering courage amid many shadows, carrying as his burden the unutterable doubts and woes of others, the fullness of his responsibilities known to Omniscience alone.

DIFFERENCES BETWEEN SOFT CHANCRE AND SYPHILIS.

Soft Chancre.	Syphilis.
1. Appears immediately after infection.	1. Does not appear for several weeks after infection.
2. Primary lesion soft and devoid of induration; suppurates.	2. Primary lesion hard, indurated, seldom suppurates.
3. Sore generally multiple.	3. Sore generally single.
4. Is auto-inoculable.	4. Not inoculable on the same subject.
5. Followed by suppurating bubo.	5. Followed by indurated bubo
6. Bubo single.	6. Buboes multiple.
7. Not followed by secondary or tertitary manifestations.	7. Generally succeeded by secondary and tertiary manifestations.
8. Constitution not contaminated—a local disease.	8. A constitutional disease.
9. Not capable of hereditary transmission.	9. Capable of hereditary transmission.
10. Does not require mercury for its cure.	10. Requires mercury for its cure.
11. Capable of being destroyed by caustics.	11. Not capable of being destroyed by caustics.
12. Does not protect from future attacks.	12. Protects from future attacks.

M. B. WERNER, M. D.
PHILADELPHIA, PA.

Treatment of syphilis by subcutaneous injections of a five per cent. solution of sublimate. (Wiener Klin, Woch., 1892). The happy results of Lassar and Oestricher following the use of injections of sublimate solution in 100 unselected cases, served as an impetus to the author of the present paper, W. Lukasiewiez to make further investigations. The solution used was as follows:

Sublimat., 0.5, sodium chlor., 0.5, aq. dest., 10.0, a syringeful of this injected weekly into the gluteal region. In the eleven patients under treatment Lukasiewiez, noticed a slight rise in the temperature after the first injection. Examination of the blood showed an increase of the red blood corpuscles, and a rise of its specific gravity; this was observed only during the first few days, proving a primary thickening of the blood. The number of injections varied in each individual case between 4–12. Considering, however, the rapid excretion of the mercurial salt the author thinks it best to give no less than six to eight injections to establish a cure. The results are usually prompt, improvement in the general health, the syphilitic manifestations disappear rapidly, even in cases which have failed to respond to other methods of treatment. It was the exception to have a slight infiltration follow the injections; these as a rule were not painful.

N. P. Krawkow (*Centralb f. Medizin., Wiss.*, No. 14, 1892) in his studies upon the origin of diabetes made upon the individual organs of dead subjects, arrived at the following conclusions:

1st. Carbo-hydrates could be produced in all the organs in considerable quantities—the liver, however, giving the least.

2d. The glycogen of the organs furnishes the sugar by a retrograde metamorphosis of its cells.

3d. There is a constant comparative fluctuation between the amount of glycogen and sugar.

4th. The distribution of glycogen among the organs deviates markedly from the normal when diabetes is present, and it is found in such organs where it is absent under normal conditions; for instance, in the brain.

5. The occurrence of glycogen in diabetes must not be placed in comparison to the inflammatory processes. Diabetes is recognized by the presence of glycogen as well as sugar.

6. The cartilaginous tissues of diabetics suffer marked changes in connection with the formation of the carbo-hydrates.

7. The increased production of sugar in diabetes, can be explained by the increased production of glycogen, and general reduction of strength in the organism, this latter resulting in a lack of appropriation of the produced glycogen.

8. The theory of carbo-hydrate atrophy of the tissues is the best one suited to explain the symptoms of diabetes.

H. Schlange: Irreducible luxation of the knee-joint (Deut. Med. Woch., No. 15, 1892). Patient, æt. 58, fell some distance and was caught by the right leg between two boards. Flexion or abduction as well as rotation of the leg, all showed a marked flattening of the right knee joint, due to an outward displacement of both tibia and fibula. The external condyle of the femur could be felt on the inner articulating surface of the tibia. The patella was also displaced outwardly. Varied efforts were made at reduction under narcosis, but without success. An incision over the prominent external condyle of the femur disclosed that bone tightly fixed in a rupture of the capsule near the head of the tibia; reposition became possible only after enlarging this tear. Both ligamentæ cruciata were torn, as was also a portion of the vastus externus muscle, one handsbreadth above the rupture of the capsule. This complication together with an extensive ulcerative eczema below the knee, made it necessary to tampon the wound and capsular tear, the external wound being only partially closed. The tampon was removed after 2 days and the entire wound closed. This resulted in an uninterrupted recovery, with a restoration of almost normal function. The author calls attention to an analogous case reported by Braun, in which, however, the rotation of the leg was inward. The treatment also consisted in the reduction by cutting operation, the wound was washed with a 3 per cent. sol. of acid carbol., and drained—healing was slow and unsatisfactory—followed by anchylosis. Schlange concludes by stating that progressive knowledge in surgery was the cause of his success.

Poppert: (Munich Med. Woch., 1892) reports a case of ileus induced by tubercular peritonitis and cured by abdominal section. Case, female, 11 years, was admitted to the surgical clinic at Giessen. The condition of the patient was so poor, that it was deemed best to make a fistulous opening into the small intestine, the numerous adhesions making it possible to extend operative procedure. The result was excellent, the symptoms of ileus at once disappeared, and in a few days a normal movement occurred and the intestinal fistula closed spontaneously.

V. Gross: A case of tubal pregnancy, internal hæmorrhage, death. (Corresp-blat. f. Shweitz Aerzte, 1892). Patient, æt. 38, enjoyed previous good health, was suddenly attacked with vomiting and faintness, pain in the left side of the abdomen, ringing in the ears, feeling of fear, and dyspnœa. Her condition was not recognized by her physician, who treated her for influenza of the abdomen. The treatment consists of hot poultices on the abdomen, injections of tincture of musk, champagne. Death occurred the same evening. Section revealed a ruptured tubal pregnancy.

APOSTOLI'S METHODS.

Apostoli's clinic, according to a contemporary, is daily overcrowded by patients and physicions, which evidences the fact that his results are satisfactory to those most interested. For this method of treatment it often requires much confidence and forbearance on the part of the patient, and patience on the physician's part. Apostoli's method of administering the treatment, especially taxes the good nature of his patients. He requires each one to make preparation by removing every article of clothing, except a loose wrapper, and places her on a high table, with the wrapper drawn over the breast, so as to expose her from the ribs down. She there receives an antiseptic vaginal douche, and his large, cold, clay electrode is then clapped suddenly on the sensitive abdomen. All this must be exceedingly trying to a patient, being performed in the presence of ten to fifteen strange physicians from all parts of the world. It is difficult enough for American patients to submit to the slight incidental pain, in a private office and no exposure of person.—*Med. Review.*

Abstracts.

A SUBSTITUTE FOR INTUBATION.

L. L. Palmer, M. D., in the Ontario Medical Journal, Oct. '92, says that from reports, one might conclude that intubation was short lived. He has observed that most criticism comes from those of little or no experience, or unable to perform intubation. He believes it has come to stay, and is more preferable than tracheotomy. But the majority of physicians are not equipped with O'Dwyer's tubes and many lives are lost that otherwise might be saved.

He says the indication for intubation is stenosis, due to two conditions. (1.) Inflammatory tumefaction. (2). Exudation: Both of which may combine to close the larynx, or either, predominating, may cause asphyxia and death. Tumefaction is not always the chief factor. The exudation may become so thick and extensive as to be the sole cause of dyspnœa, which if removed, almost normal respiration is restored.

For this purpose he has devised a fine brush, upon a bent platinum probe—hair pointing upward; so that it is easily introduced and offers greatest resistance on removal. The same probe may be used, wound around with absorbent cotton. This should be carefully introduced into the larynx, using no force.

Not more than five or six seconds, should be occupied in introducing and removing it. The child's body and head being held erect. The membrane is readily removed. If any remain, it is so loosened that it is brought up by the child's coughing.

This procedure should be used as often as necessary.

He concludes that no physician is justified in allowing a child to die asphyxiated, from diphtheritic membrane, without resorting to this simple expedient.

TREATMENT OF STRANGULATED HERNIA.

Dr. W. B. De Garmo, in the Post Graduate, says that there is no branch of surgery wherein so many lives have been needlessly sacrificed as in the treatment of strangulated hernia. The practitioners either do not recognize the grave condi-

tions, or else being unable to operate, waste precious time employing taxis, until it is too late to call a surgeon.

Delays are fatal. Too much time should not be spent in trying one after another of the many remedies recommended for this serious condition. Inasmuch as the trouble is a mechanical one, every physician should be competent and ready to operate at any time. The theory is untrue that muscular spasm is an active cause of strangulated hernia. It is a waste of words to name the different remedies. Opium has cost many a person his life; it quiets fever and pain, masks the symptoms, but the pathological changes are going on while both physician and patient are deceived. The means for relief before operating may be considered briefly as follows:

1. Morphia, hypodermically, for relief of pain only.
2. Sulphuric ether applied to tumor.
3. Taxis gently and intelligently applied.
4. Taxis under anæsthesia.

The early application of ice was for many years considered the safest procedure. To reduce the tumor, he prefers the application of ether, as being the best and safest.

Great injury is often done by rough manipulation, in trying to effect a reduction. The most extreme care and gentleness should be observed. If reduction does not follow taxis when ether is systematically used, then taxis should be employed under anæsthesia, which has the double advantage in case manipulation fails, then the patient is ready for operation which should be immediately done, every thing having been gotten ready beforehand.

The operation is not a difficult one, only requiring a steady hand and cool head. To those who have never operated the following conditions are pertinent:

1. Instruments necessary.
2. Asepsis and antisepsis,
   - a. Of operator and assistants.
   - b. Patient.
   - c. Instruments.
3. The incision.
4. Opening of sac.
5. Treatment of intestine.
6. Treatment of omentum.
7. Completion of operation.

Only few instruments are necessary, a scalpel, artery clamps, groove director, scissors, ligatures, sponges, needles, gauze, different kinds, and bandages. Make every thing aseptic, special care being paid to the nails of assistant physician. The primary incision should be made over the bulk of tumor reaching the neck of tumor as soon as possible. When the hernial sac is exposed, it serves as a guide to the opening through which it protrudes. Having found the seat of constriction, the question will arise, whether to cut this band and reduce the sac without seeing its contents. Opening the sac does not materially increase the risk of operation, if the operator is clean.

The bowel should be thoroughly examined and treated according to its condition; good surgery should be strictly carried out.

The next consideration is to complete the operation, giving the patient the best possible chance for a permanent cure. In order to do this the inguinal canal must be placed in as nearly a normal condition as possible. He practices cutting off the sac as near the inguinal ring as possible and then stitching up the canal with heavy braided silk, which is left in situ. The wound is properly closed and dressings are applied. Loops of intestine, having been subjected to pressure, are liable to partial paralysis. For this condition, he recommends giving a mild saline cathartic on second day. The use of opium is discouraged unless urgently demanded for the relief of pain.

AMPUTATION OF THIGH.

Dr. Nicholas Sinn, in a clinical lecture delivered at the annual meeting of the association of military surgeons, said that there are only a few essential principles that become necessary to memorize and to carry into effect in amputating through any part of the lower or upper extremities. If it is remembered to make the incision, so as to bring the resulting scar away from pressure in wearing an artificial limb. To preserve the periosteum, and to amputate the principal nerve trunks at least an inch above the level of the incision through the soft parts, which prevents a neuroma, and under all circumstances to secure complete hæmostasis.

He says, "that it makes his blood curdle and hair stand on end" when in this progressive time and age, men are held up in courts of justice, to answer a mal

practice suit, for having made a posterior long or lateral flap. Old text-books are still revered by lawyers, but are of little use to the surgeon. The proper plan is to take the flap from any region best adapted to serve as a covering for the stump.

Dr. Senn has discarded the use of the elastic bandage in rendering a limb avascular and empties the blood-vessels by simply elevating the member. He believes that the use of the elastic bandage is not only superfluous, but in all pathological conditions especially, is very dangerous, as its application from the distal part to and over the diseased point to the proximal side, may force the pathological process into the general circulation, which might be the cause of a dissemination of the process. When the limb is rendered avascular by elevation he interrupts the circulation at once by sudden proximal compression. He avoids linear compression by using a broad constrictor, and protects nerve structures by using a thick layer of gauze under the constrictor, when its superficial part cannot be avoided.

THE ETIOLOGY OF ATROPHIC RHINITIS.

Dr. W. B. McClure, in The American Practitioner and News, says that chronic hypertrophy of the nasal mucous membrane may ultimately result in atrophy of that membrane. After a long period of investigation and careful study of this disease, he arrives at the following conclusions:

(1) Atrophic rhinitis is the ultimate and logical result of neglected hypertrophy of the nasal mucous membrane and never occurs as a primary disease.

(2) Its chief cause is from lack of nutrition caused by cutting off its blood supply.

(3) The atrophic process is by desquamative inflammation.

(4) That the beginning of atrophy, is superinduced by hyperæmia of the membrane.

THE LOCAL USE OF PHENACETIN.

Dr. M. A. Lee, in the Memphis Medical Monthly, records another use for phenacetin.

Having a case of chronic ulcer of the leg, on which he had used all the local applications, commonly prescribed, for such conditions, without success; it occurred to him to try the use of phenacetin.

The sore was thoroughly cleansed and the drug, finely powdered, was dusted over the ulcer three times daily.

Improvement immediately followed. The treatment was continued, resulting in a complete cure.

Having a number of other cases, he pursued the same treatment, with most pleasing results.

In order to be effective the sore must be thoroughly cleansed and the patient placed on supportive treatment and good nourishing diet.

SCIENCE AND WOMEN.

Professor William James, of Harvard, announces that woman develops early and then ceases to grow mentally. Professor Crichton Browne finds that women's brains are smaller than men's, and their frontal lobes less richly supplied with blood, Professor Lombroso finds that women are less sensitive than men, and, as regards their receptive and perceptive organs, represent an incompletely developed type. Altogether, science is bearing down very hard on the ladies. Yet we do not learn that they are becoming any the less popular. The poet has said metrically that without them the extremes of life would be without solace and its middle without joy. The testimony of the poet will probably continue to be received by the mass of human kind, even if the greatest cranial circumference of the gentler sex never rises above fifty centimetres.

BOOKS RECEIVED.

Text-book of Ophthalmology. By Dr. Ernest Fuchs, Professor of Ophthalmology in the University of Vienna. Authorized translation from the second enlarged and improved German Edition, By A. Duane., M. D. Assistant surgeon Ophthalmic and Aural Institute, New York. New York: D. Appleton & Co., 1892.

A Handbook of Hygiene and Sanitary Science. By George Wilson, M. A., M. D., F. R. S. Edin., etc. Seventh Edition. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street, 1892. $3.25

Aene and Alopecia. By L. Duncan Bulkley, A. M,. M. D. The Physician's Leisure Library Series, 1892; George S. Davis, Detroit, Mich. 25 cents.

The Mastoid Operation, Including its History Anatomy and Pathology. By Samuel Ellsworth Allen, M. D. Cincinnati: Robert Clark & Co., 1892.

A Public Scandal: An Exposure. By Frank S. Billings, M. D. Printed and published at the expense of the author.

Souvenir of Asheville, or the Sky-Land. By Mrs Harriet Adams Swayer, St. Louis. Nixon-Jones Printing Co., 1892. Sent by Author on receipt of 75 cents.

Alaskana, or Alaska in Descriptive and Legendary Poems. By Prof. Bushrod W. James, A. M., M. D., Philadelphia: Porter & Coates, 1892.

Periscope.

THERAPEUTICS.

PHENACETINE.

Dr. John V. Shoemaker, in writing on the subject of the treatment of influenza, states that the aching pains yield most readily to phenacetine, given in doses of two or three grains, repeated at intervals of two hours, until the desired effect is obtained. From two to four doses have usually been sufficient. No ill effects usually result from the same dose of phenacetine. Some prefer to give larger doses of this drug at longer intervals. Others, again, praise a combination of phenacetine and salol, two or three grains of each repeated. Other antipyretics should be avoided, as phenacetine is by far the safest of the agents. Moreover, but few doses are usually required, when the drug can be replaced by tonics, especially small doses of strychnine or nux vomica. Phenacetine has also the advantage of acting upon the skin.—*Ont. Med. Jour.*

COCAINE ANTIDOTES.

S. Mitchell (*Medical Record*) has found that while ammonia, digitalis and brandy will relieve the milder toxic manifestations of cocaine poisoning, they signally fail when these symptoms are superseded by severe præcordial pain, weak and rapid pulse, sighing respiration, borborygmus and belching of wind, muscular rigidity, and, later, paralysis of the whole body except the brain, which is unnaturally active. In such a case he used a large teacupful of clear coffee, and has found it equally efficacious on subsequent occasions. It can be administered cold or hot. He makes no mention of amyl nitrite.

Gluck (*Ibid*) advocates dissolving the cocaine in a three per cent. solution of phenol. This, he claims, prevents the toxic effects of the former drug and renders the solution stable; as is well known, such solutions otherwise lose their anæsthesic effects after twenty-four hours. Phenol, besides, has a certain anæsthetic power of its own, forms a superficial eschar, which prevents absorption of the cocaine, destroys bacteria, fungi, etc., prevents decomposition in the solution, renders it aseptic, and wards off reactive congestion.

BISMUTH SUBNITRATE IN BURNS—NEW MODE OF EMPLOYMENT.

In burns, Dr. K. von Bardeleben, of the Friedrichshain Hospital, Berlin, employs tarlatan bandages impregnated with a mixture of equal parts of bismuth subnitrate and powdered starch. These bandages are applied directly to the affected parts, which are previously washed and disinfected with a three per cent. solution of carbolic acid or with a three-tenths per cent. solution of salicylic acid. The first dressing of this kind is left in place at least eight days, and if necessary, for two and even four weeks.

As can readily be seen, this dressing is not applicable to burns of the face, which we would be compelled simply to powder with bismuth—a procedure which the author regards as defective and slovenly, and one in which a considerable quantity of the medicament is wasted.

In burns occasioned by chemicals, it is deemed necessary, before applying the bismuth dressing, to neutralize the caustic which has penetrated the tissues, by means of washing with lime water if an acid was the escharotic, or with vinegar if the burn was produced by an alkali.—*Merck's Bulletin.*

SALOL IN GONORRHOEA.

Dr. E. C. Underwood says that salol can reduce the duration of gonorrhœa to the lowest limits. This method consists in the regular employment of from forty to sixty grains of salol through the day. "I order my patients to have four doses of from ten to fifteen grains each, taken immediately on rising in the morning, at 11 o'clock A. M., 4 o'clock P. M., and the last thing on retiring to bed. At first, I ordered it in powders or compressed tablets. But learning that many of these tablets passed through the intestinal canal without being absorbed, and in the form they were administered, I am now using the drug in powder form. It is tasteless and is not complained of by patients. The dose is begun, unless the patient shows that the drug disagrees with him, with sixty grains a day, and continued until the discharge has become very meager. Then it is gradually lessened." The author claims that better results follow this method than any other.—*Atlanta Medical Journal.*

ICE IN DYSENTERY.

In dysentery, when the lower part of the colon is affected, the local use of ice sometimes has an almost marvellous effect. H. C. Wood has seen the whole aspect of a very severe and alarming case, in which the symptoms indicated that the colon was affected high up, changed in a single hour by the continuous use of ice suppositories. While it is not necessary to have the pieces of ice entirely regular in shape, care should be exercised that no sharp edges are left. The suppositories should be rapidly used, one being put into the rectum every three to five minutes, so as to get, for at least half an hour to an hour, the effect of the continuous application of cold. When the tenesmus is very severe, iodoform suppositories are often much more efficient than opium in bringing relief.—*Memphis Med. Monthly.*

EUCALYPTOL BY INHALATION IN PULMONARY PHTHISIS.

Dr. Marche reports that he has for more than a year been treating all cases of pulmonary tuberculosis by means of inhalations of Eucalyptol, associated with creasote. Into a saucepan holding 1-2 liters [about 1-2 quarts] and filled with water, he pours per litre 1 or 2 spoonfuls of the following solution (*Med. Mod.*):

Eucalyptol	20 parts.
Creosote (Beech-wood)	8 "
Alcohol	72 "

The whole is made to boil over an ordinary oil-stove; when the saucepan is almost empty, it is refilled with water, the solution added, and the whole heated, as before. The patient should be placed in a pretty spacious but well-closed room, and remain there as long as possible.

This medication the author has continued uninterruptedly for several months without provoking the least sign of intolerance. It therefore appears worthy of a trial; but, of course, it is not destined to replace the hypodermic method of treating phthisis.—*Merck's Bulletin.*

ZINC OXIDE IN HYSTERO-EPILEPSY.

Only a very short time ago Dr. P. Cascini related the favorable results he had obtained from quinine in certain cases of hystero-epileptic convulsions of a periodic type (see August number of *Merck's Bulletin*, p. 450). Now Dr. Niermeyer of Amsterdam recommends against that same affection, so rebellious to therapeutic means, another medicament just as old, formerly often employed in the capacity of a nervine but at present more or less forsaken,—and that is zinc oxide. Of 20 cases of hystero-epilepsy that had resisted all other medicaments so far employed, the author obtained considerable improvement in 15, even in a few days, from the administration of zinc oxide in doses of 50 centigrammes [7½ grains] in the course of twenty-four hours (given with equal parts of powdered valerian or rhubarb). He therefore feels justified in recommending zinc oxide in the treatment of the convulsive paroxysms of hysteria.—*Merck's Bulletin*, October, 1892.

A TREATMENT OF SEBORRHOEA OF THE SCALP.

Dr. Saalfeld (*La Rif. Med.* No. 98, 1892), in cases of seborrhœa of the hairy scalp, with a tendency to alopecia, recommends the following method: At night scrub the roots of the hair energetically with an alkaline solution of green soap, and pour on a little tepid water to cause the soap to foam; leave this foam on the scalp for a few minutes; removing this with tepid water and then apply the following salve:

℞

Flowers of sulphur (grs. xlv-℥jss).	gms. 3-5
Lanoline (grs. xlv).	gms. 3
Benzoated lard (℥j).	gms. 30

This salve prevents the formation of crusts in excess. If the patient suffers from pruritus, which is often the case, then add thirty to fifty centigrammes (5 to 8 grains) of salicylic acid, previously dissolved in a slight quantity of rectified alcohol. Wash the hair and apply the salve, at first every day, and when results are obtained every eight to fifteen days.

SILVER NITRATE IN GONORRHOEAL EPIDIDYMITIS.

According to Dr. T. Trzcinski, physician to the Hospital Saint-Lazare at Warsaw, blennorrhagic orchi-epididymitis may be aborted in the beginning by means of local revulsion with a 1:10 ointment of silver nitrate. He completely envelops

the diseased testicle with a small linen compress spread with a pretty thick layer of this salve; then he places cotton over the compress, applies a suspensory, and leaves the dressing in situ for twenty-four hours, which the patient should pass in bed.

It is stated that the application of the ointment provokes an intense burning sensation, which, however, dies out in an hour or two; but, at the same time, the testicular pain considerably diminishes. Twenty-four hours afterward, when the dressing is removed, the scrotal skin is found partly colored black and partly red and moist, and it is observed that the testicle has become much less painful. A simple dressing of cotton is then applied for twenty-four hours, and after that the patient wears a padded suspensory.—*Merck's Bulletin*, October, 1892.

FROST BITES—(TREATMENT.)

[Paschkis—*Ther. Monatsh.*]

—LINIMENT.—

Tannic Acid..... 1 part.
Glycerin (or Camphor Spirit).....25 parts.
Externally!

or:

Tannic Acid..... 3 parts.
Alcohol..... 5 "
Collodion.....20 "
Benzoin Tincture..... 2 "

[Carrie.]

—OINTMENT.—

Powdered Camphor..... 3 grammes [45 grains].
Lanolin } of each, 15 " [½ ounce].
Vaselin }
Hydrochloric Acid..... 2 " [½ fl. dr.]
Rub-in at night!

[Rust.]

—PAINT.—

BLACKENING OF THE TEETH BY ANTIPYRINE.

It is asserted that the internal use of antipyrine blackens the teeth; this peculiarity should be generally known by the profession, and also among the laity, that objections may be made on this ground to taking it as a remedy. The blackening is the more intense, the more imperfect the enamel, but may be removed by attrition with dilute acid. The considerable use of antiprine for several years back, gives importance to this last observation.—*Ontario Medical Journal.*

EXOPHTHALMIC GOITRE.

Dr. Dieulafoy, writing in the *Bulletin Medical*, says that in cases of exophthalmic goitre the aim of treatment should be to lower the vascular excitement. He compares patients with this affection to those threatened with pulmonary hemorrhage, and treats them in the same way. He gives from four to six pills a day, made according to the following formula:

℞ Pulve. ipecac..... grs. vj.
Pulv. digitalis..... grs. iv.
Ext. opii..... grs. ss.
M. et. ft. pil. No. xij.

The only inconvenience of this medication is an occasional diarrhœa, which may be troublesome until a tolerance is established.

PERMANGANATE POTASSIUM IN THE TREATMENT OF DIPHTHERIA.

Bown reports (*Ex.*) several cases of diptheria in which most excellent results were obtained by the use of a solution of permanganate of potash of the strength of three grains to the ounce. Three or four applications an hour were made directly to the membrane with a large camel's-hair brush for eight or twelve hours. After this once every two to six hours is sufficient. In some cases a spray is a better method of application.—*Med. Review.*

SURGERY.

THE ANTISEPTIC TREATMENT OF GONORRHOEA.

Dr. Vatier (*La Rif. Med.* No. 100, 1892,) in order to avoid the the pain which corrosive sublimate produces when used as an injection strong enough te exercise an antiseptic effect in gonorrhœa, associates antipyrin with it in the following formula:

℞ Antipyrin..... gms. 5
(5jss).
Corrosive sublimate..... gms. 05
(gr. j).
Aqua..... O j.

This combination of remedies permits one to begin the treatment at any period

of the disease. It may also be used as a preventative. The solution should be allowed to remain not less than half an hour in the urethra. Inject three or four times a day. In general, inject as often as one urinates.

OPERATIONS ON THE NOSE.

Dr. Clarence C. Rice concludes (*Post-Graduate*) the only way to become skillful with instruments of examination and expert in diagnosis is to personally examine the upper respiratory tract of as many patients as possible. Cases for operation on the nose should be selected only after careful deliberation, and the relation in size between the obstruction and the total capacity of the nostril should be considered. When in doubt about the necessity for operation, try for a time treatment by topical application. There are many cases of so-called "hypertrophic rhinitis" where the apparent hypertrophies are nothing more than erectile tissues distended by blood or serum, and many of these do not require the application of any destructive agent. The effect of a weak solution of cocaine upon these will aid in their diagnosis. We do not find advanced hypertrophic changes in young people. The soft tissues are usually nearly normal, so it is not wise to injure physiological tissues by operative procedure. Deformities of the nasal septum are usually the first pathological condition to appear, and are the cause of the later changes in the soft structures of the nose. The removal of this septal lesion should first claim the attention of the operator. Do not produce by operative measures large ulcerations on the septum, if they can be avoided, as there may be present in the case some constitutional vice, and therefore the ulcerations will be healed with difficulty. Nothing is more efficacious in their treatment than the use of antiseptic washes and covering.

TTEATMENT OF APPENDICTIS.

Dr. Senn's conclusions are these, viz.: (1) All cases of catarrh and ulcerative appendicitis should be treated by laparotomy and excision of the appendix as soon as the lesion can be recognized. (2) Excision of the appendix in cases of simple, uncomplicated appendicitis is one of the easiest and safest of all intra-abdominal operations. (3) Excisions of the appendix in cases of appendicitis before perforation has occurred is both a curative and prophylactic measure. (4) The most constant and reliable symptoms indicating the existence of appendicitis are recurring pains and circumscribed tenderness in the region of the appendix. (4) All operations should be done through a straight incision; parallel to and directly over the cæcum. (6) The stump after excision of the appendix should be carefully disinfected, iodoformized, and covered with peritoneum by suturing the serous surface of the cæcum on each side over it with a number of Lembert stitches. (7) The abdominal incision should be closed by two rows of sutures, the first embracing the peritoneum, and the second the remaining structures of the margins of the wound. (8) Drainage in such cases is unnecessary, and should be dispensed with.—*Medical Progress.*

MEDICINE.

THE TREATMENT OF INSOMNIA.

Dr. Joseph Collins, of New York, in an interesting article on insomnia, published in the *Journal of Nervous and Mental Diseases*, contrasts the action of chloralamid and sulfonal in the treatment of insomnia, and arrives at the following conclusions:

1. Chloralamid is a safe and one of the most reliable hypnotics.

2 It is not ordinarily followed by distressing after-symptoms, particularly headache.

3. It is especially valuable as a hypnotic where pain is a prominent factor, but not violent.

4. In cases of insomnia, where there is excessive activity of the brain, it is also useful.

5. On account of its stimulating activity on the respiratory function, it is the hypnotic *par excellence* in nervous exhaustion, associated with an asthenic condition of respiration and symptom complex indirectly dependent on this, brought about by defective oxidation and the formation of unstable chemical compounds in the system.

6. On account of its very slight action in depressing the circulation, it can be given in diseases associated with a weak heart, with greater safety than most of the other

hypnotics, not excepting chloral itself.

7. It is conveniently administered in the shape of an elixir, and this overcomes the need of dissolving it.

8. Its dose is from one to three scruples, administered one hour before sleep is desired, and this should not be repeated within two hours, for occasionally the action of the drug is delayed.

Sulfonal is preferred when we wish to get very rapid action. It should be given dissolved in boiling water, taken as hot as possible. In this way it is at once absorbed, sleep frequently occurring in from fifteen to twenty minutes. The disadvantages of sulfonal are that the patient is liable to form the sulfonal habit, and that its effects last through part of the following day.—*West. Med. Reporter,* Oct. 1892.

MASSAGE.

The clinical results obtained by massage are as follows:

In simple contusions, it brings about the rapid disappearance of divers disturbances, especially pain.

In contusions of the joints, it dissipates the muscular reflex contractures or the pareses, but above all it prevents obstinate amyotrophy which is the most serious of complications.

Applied to sprains, it is remarkable for the rapidity of its good effects; the looked for result is obtained in three or four days.

In dislocations, recourse must be had to it as soon as the reduction is assured, as it reduces, in the shortest time the swelling, ecchymosis, and pain; it arouses the muscular fiber from that local stupor into which it is plunged by the traumatism, and it prevents atrophy and lingering stiffness.

Applied to juxta-articular fractures, it soon subdues both pain and swelling; if recourse is had to it after the removal of apparatuses, it limbers up the parts and dissipates the œdema. A simple fracture, without deformation of the lower end of the radius, is cured in a fortnight; whereas, at least, forty days are necessary when immobilization with plaster dressings is resorted to.

Against *acquired aymotrophy*, massage shows itself powerless; if applied in the earliest stages, it may prevent the further progress of the affection.

The clinical conclusions are based on the histological results; a wounded muscle to which massage is not applied presents a diffuse sclerosis, with hypertrophy of the adjoining connective tissue in the various parts, interstitial hæmorrhage, engorgement of bloodvessels, and hypertrophy of their outer coat; whereas a wounded muscle, treated with massage, offers a normal histology. This is *restitutio ad integrum.*

The bloodvessels are normal in the muscles to which massage has been applied; in the muscle not so treated, they present a hyperplasia of the external tunic. The nerve filaments, normal in the muscle to which massage has been applied, shows signs of perineuritis and interstitial neuritis in the muscle not treated with massage.

The lesion of the nerves is more marked than that of the bloodvessels.

Upon the whole, according to the researches made by the author, it is proven, *de visu*, that massage acts by deterging a part of the variously noxious substances which the traumatism has introduced, by bringing the affected part back to its normal state and by preventing the process of diffuse sclerosis which would otherwise result.—*Merck's Bulletin.*

HYGIENE.

WATER FOR BABES.

A physician of New York Nursery and Child's Hospital believes, from his practice, that infants generally, whether brought up at the breast or artificially, are not supplied with sufficient water, the fluid portion of their food, being quickly taken up, leaving the solid too thick to be easily digested, In warm, dry weather, healthy babies will take water every hour with advantage, and their frequent fretfulness and rise of temperature is often directly due to their not having it. A free supply of water, and restricting the frequency of nursing, has been found at the nursery to be a most effectual check in cases of incipient fever, a diminished rate of mortality and marked reduction in the number of gastric and intestinal complaints being attributed to this cause. In teeth cutting, the water softens the gums, and frequently stops the fretting and restlessness universal in children at this period.—*American Analyst.*

PURIFYING WATER.

Dr. Daremberg, writing in *La Med. Moderne* concerning the means of rendering a cholera-infected water innocuous, says that this end may be accomplished in one of three ways, viz., by filtering, by boiling, or by the addition of some chemical substance which will destroy the germs of the disease. The first of these methods is, as a rule, ineffective, and can be relied on only when every detail is most scrupulously attended to. The second is effective but troublesome, and cannot always be carried out, fire and a suitable vessel for boiling being indispensable. The third method is one which, he says, is equally effective with boiling, and which can be carried out anywhere and at any time. The purification of water has been effected through the addition of alum, but the author prefers the acidulation of the water, especially in the case of possible cholera infection. Citric acid may be added to the water in the proportion of sixty to eighty centigrammes to the litre. This method is inexpensive, does not impart any unpleasant taste or odor to the water, and can be done anywhere without the need of cumbersome or delicate apparatus. In place of citric acid, tartaric or hydrochloric acid may be used, if desired.—*N. Y. Med. Record.*

NEWS AND MISCELLANY.

A PAINFUL INCIDENT.

A correspondent of the Vienna *Abendblatt* is responsible for the following statement: One morning the medical superintendent of a large lunatic asylum requested an attendant to hand him a pair of scissors. Perceiving something unusual in the aspect and demeanor of his chief, the attention of one of the physicians was drawn to the circumstance, when he was both surprised and alarmed by the announcement from the lips of the superintendent that it was his intention to open the skulls of some of his patients in order to ascertain the exact condition of their cerebral development. It thus became evident that the brain which had been for so long responsible for the medical oversight of the afflicted inmates of his asylum had itself become deranged, a circumstance not unique in the history of neurological research.—*Lancet.*

GOOD BEDSIDE MANNERS.

The day has not disappeared far in the past, in fact, has not altogether disappeared when a good bedside manner was the great requisite for success. If the doctor was gentle to the women, and attractive to the children, his success was assured. This is true to a certain extent today, but it is disappearing at the approach of the dazzling light of modern research. The coming physician is the one who will demonstrate his ability to combat disease. The man who can prove by actual demonstration that he understands the *antitoxines* is the one who is coming to the front. An American surgeon of to-day who has astonished a world by his statistics, astonishes alike all those who see how easily he operates without display and with scarcely a handful of instruments. But his patients recover. We would not underrate the value of a good bedside manner; but the scholar is coming to the front. Brains are at a premium.—*National Med. Review.*

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY FROM NOVEMBER 6, 1892, TO NOVEMBER 12, 1892.

Leave of absence for four (4) months, with permission to apply for an extension of two months is granted Major Justus M. Brown, Surgeon, U. S. Army.

Captain Eugene L. Swift, Assistant Surgeon, U. S. Army, is granted leave of absence for one month, to take effect upon expiration of present sick leave.

ELEVENTH INTERNATIONAL MEDICAL CONGRESS.

(Rome, September 24th to October 1st, 1893.)

The American Sub-Committee has the following membership: W. T. Briggs, Nashville, Tenn; H. P. Bowditch, Boston, Mass; S. C. Busey, Washington, D. C.; C. Cushing, San Francisco, Cal.; N. S. Davis, Chicago, Ill.; A. Jacobi, New York, Chairman; Norman W. Kingsley, D. D. S., New York; Wm. Osler, Baltimore, Md.; Wm. Pepper, Philadelphia, Pa.; F. Peyre Porcher, Charleston, S. C.; Charles A. L. Reed, Cincinnati, O; D. B. St. John Roosa, New York; Alex. J. C. Skene, Brooklyn, N. Y., and James Stewart, Montreal, Can.

The Secretary General informs the Committee, that the French Railway Company has offered to the members of the Congress a reduction of fifty per cent. on its fare.

Galenical Preparations

MANUFACTURED BY

WILLIAM R. WARNER & CO.

MANUFACTURERS OF SOLUBLE COATED PILLS.

FOUNDED 1856

Standard and Officinal Preparations for Physicians Only.

Pil. Sumbul Comp.

(WM. R. WARNER & CO.)

DR. GOODELL.

℞ Ext. Sumbul . . 1 gr. | Ferri Sulph. Ext. . . 1 gr.
Assafœtida . . . 2 gr. | Ac. Arsenious . . 1-30 gr.

"I use this pill for nervous and hysterical women who need building up." This pill is used with advantage in neurasthenic conditions in conjunction with Warner & Co.'s Bromo-Soda, one or two pills taken three times a day.

Pil. Lady Webster.

(WM. R. WARNER & CO.)

℞ Pulv. Aloes . . 2 gr. | Pulv. Rose los . . . ½ gr.
" Mastic . . ½ gr. | M. ft. one pill.

Lady Webster Dinner Pills. This is an excellent combination officinally designated as Aloes and Mastich, U. S. P. We take very great pleasure in asking physicians to prescribe them more liberally, as they are very excellent as an aperient for persons of full habit or gouty tendency when taken in doses of one pill after dinner.

Pil. Digestiva.

(WM. R. WARNER & CO.)

A VALUABLE AID TO DIGESTION.

℞ Pepsin Conc't . 1 gr. | Gingerine . . . 1-16 gr.
Pv. Nux. Vom. ¼ gr. | Sulphur . . . . . ⅛ gr.

IN EACH PILL.

This combination is very useful in relieving various forms of Dyspepsia and Indigestion, and will afford permanent benefit in cases of enfeebled digestion, where the gastric juices are not properly secreted. As a dinner pill, Pil. Digestiva is unequalled, and may be taken in doses of a single pill either before or after eating.

Pil. Antiseptic Comp.

(WM. R. WARNER & CO.)

EACH PILL CONTAINS

Sulphite Soda . . . 1 gr. | Powd. Capsicum . 1-10 gr.
Salicylic Acid . . . 1 gr. | Concentrated Pepsin 1gr.
Ext. Nux Vomica . . ⅛ gr. | Dose—1 to 3 pills.

Pil. Antiseptic Comp. is prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food. TAKE NO SUBSTITUTES.

LITTELL'S LIVING AGE

1844.

1893.

In **1893** will enter its **YEAR OF JUBILEE,** hence a retrospective glance at its history may be now appropriately taken.

In establishing this magazine its founder sought to present in convenient form a history of the world's progress, by selecting from the whole wide field of European Periodical Literature, the best articles by the most eminent writers in every department, Biography, History, Literature, Travels, Science, Politics, Art, Criticism, in a word, "*de omnibus rebus,*" including Fiction and Poetry.

The plan thus originally proposed has been faithfully followed during the forty-nine years of its existence, with what measure of success the uniformly high character of the articles presented to its readers for 2530 Consecutive Weeks and the contents of its 195 Octavo Volumes sufficiently attest.

A. D. 1844.

"I have never seen any similar publication of equal merit."—GEORGE TICKNOR, *August, 1844.*

A. D. 1869.

"Still as fresh, as racy, as enchanting, and full to the brim of scientific value, as when it rejoiced in its first year." ALFRED B. STREET, in *Albany Evening Journal, Nov., 1869.*

A. D. 1892.

"Only the best has ever filled its pages; the best thought, rendered in the purest English. Nothing poor or unworthy has ever appeared in the columns of *The Living Age.*"—THE PRESBYTERIAN, *Philadelphia, 13th April, 1892.*

In the coming year THE LIVING AGE will continue to be

THE REFLEX OF THE AGE IN WHICH IT LIVES.

Fiction will still occupy its accustomed place in the magazine and the exquisite short stories which appear in every number and which have been so well received during the past year will remain a prominent feature of this department.

OBSERVE! THE LIVING AGE is a *Weekly Magazine of sixty-four pages,* giving more than

THREE AND A QUARTER THOUSAND

double column octavo pages of reading matter yearly, forming four large volumes, thus presenting a mass of matter

UNEQUALLED IN QUALITY AND QUANTITY

by any other publication in the country.

The Boston TRANSCRIPT *of Sept. 5, 1892, says of* THE LIVING AGE: "*No well-ordered and intelligent household should be without this publication.*"

That every such household may be induced to subscribe for the magazine, extend its sphere of usefulness and double its circulation during the coming year, the publishers make the following

OFFERS EQUAL TO THE BEST EVER PRESENTED

for the considerasion of an intelligent and cultured class of American readers. *These splendid offers are open to all subscribers, old and new alike.*

Offer No. 1. $12.00 { Littell's Living Age, one year, postpaid . . . . . $8.00 / Ridpath's History of the U. S of America . . . . . 4.00 } For $8.50

Offer No. 2. $15.50 { Littell's Living Age, one year, postpaid . . . . . $8.00 / The Wonderful Story of Old . . . . . 7.50 } For $9.00

Offer No. 3. $19.50 { Littell's Living Age, one year, postpaid . . . . . $8.00 / Ridpath's History of the U. S. of America . . . . 4 00 / The Wonderful Story of Old . . . . . 7.50 } For $10.50

No one should delay in at onee taking advantage of the remarkable opportunities thus presented of obtaining this large amount of the most valuable reading matter at a nominal price.

Offer No. 4. { We will send RIDPATH'S HISTORY *free* to anyone sending us two *new* subscribers to *The Living Age,* and the subscription price, $16.00; or we will send a set of "The Wonderful Story of Old," for a list of three *new* subscribers and $24.00.

"RIDPATH'S HISTORY OF THE UNITED STATES,"

by JOHN CLARK RIDPATH, LL. D., author of the "History of the World," etc., has received the emphatic endorsement of leading educators and of the press of America. REV. CHAS. W. BENNETT, D. D., *Professor of History, Syracuse University,* says" Whether judged by the thoroughness of research, the accuracy of statement, or the purity of style it occupies a foremost place among United States Histories."

A SPECIAL EDITION of this great work is being prepared for our use. Send for descriptive circulars.

"THE WONDERFUL STORY OF OLD,"

by MARCUS WILSON, author of "Wilson's Historical Series," "Philosophy of History," etc., etc., is a description of the Scenes, Incidents and Events recorded in the Holy Bible, to which is added much valuable matter; the whole enriched with poetical gems, and the best thoughts of Biblical scholars and critics.

This splendid work, richly illustrated after the great masters, is pub ished in two volumes, beautifully printed on the best book paper, and handsomely bound in heavy cloth. Vol. I., 660 pages. Vol. II., 626 pages

The prices given in the above "OFFERS" *include postage on* THE LIVING AGE *only. The books must be sent at the subscriber's expense.*

THE LIVING AGE is published weekly at $8.00 a year, free of postage.

☞ **TO NEW SUBSCRIBERS for the year 1893,** remitting before Jan. 1, will be sent *gratis* the two October issues containing a powerful story by Frank Harris, *editor of* THE FORTNIGHTLY REVIEW, *entitled* PROFIT AND LOSS, and also the numbers of 1892 published after the receipt of their subscriptions.

☞ The publishers continue their popular clubbing arrangements whereby one or more other periodicals may be obtained at greatly reduced prices. **They will send THE LIVING AGE and the MEDICAL and SURGICAL REPORTER, each one year, postpaid for $11 25.**

☞ Clubbing rates and circulars more fully describing the above named works will be sent on application. Sample copies of LIVING AGE 15 cents each.

Address **LITTELL & CO., 31 Bedford St., Boston.**

THE
MEDICAL AND SURGICAL REPORTER.

No. 1865. PHILADELPHIA, NOVEMBER 26, 1892. Vol. LXVII—No. 22.

PURPURA FULMINANS IN CHILDREN.*

By CLARA T. DERCUM, M. D.,
PHILADELPHIA.

Purpura was first described by Werlhof, in 1775,and is known as Morbus Maculosis Werlhofi, or Werlhof's disease. The mild forms of this affection are known as Purpura Simplex, and the more severe forms as Purpura Hæmorrhagica. When, together with other phenomena, effusions of blood into the serous membranes of the joints occur, it is known as Purpura Rheumatica. Another form of purpura, the subject of this paper, which is as a rule rapidly fatal, was described by Henoch under the name of "Purpura Fulminans," and by Hervé as "Purpura Fondroyant," so as to express more fully the overwhelming action of this form of purpura upon the system and its almost hopeless termination.

Scarcely any reference is made in our text-books to this fulminant variety of purpura, although, in looking over the literature of the disease, which is extremely rich, I found many interesting cases recorded by American, German, French, English, Italian and Scandinavian authors.

The prodromal symptoms of all forms of purpura are generally those of malaise, with chilly sensations and a slight rise of temperature; however, the disease may be ushered in suddenly without any initial symptoms. The characteristic phenomena of this affection are the hæmorrhages which take place into the sub-cutaneous tissues, the serous cavities, the joints, the internal organs and from the mucous membranes.

*Read before the Alumnæ Association of the Woman's Medical College of Pennsylvania, May 11,1892.

In connection with the case of which I have made notes I have collected a number of others, and shall briefly report them, limiting myself, with one exception, to the cases as they occur in childhood. Some of the cases were recorded as early as 1858, before the different forms of purpura had been as clearly classified as they are now, but from the symptoms and termination, I would consider them as belonging to the fulminant variety.

Case I. On February 11, 1892, I was hastily called to see a child whom the father reported as probably dying. Their family physician, a homeopath, had been sent for, but the father was afraid the little one would die before his arrival. Upon reaching the house, the patient, a boy, four years old, was found in articulo mortis. The following conditions were noted: The face was drawn and wore an anxious, restless, distressed expression, it was so white that it could scarcely be distinguished from the pillow upon which the head rested, the lips, tongue, pharynx and buccal membranes were almost as white as the skin. There was marked retraction of the supra- and infra-clavical spaces, of the supra-sternal and epigastric regions, also of the intercostal spaces. The respirations were hurried and gasping, in fact, the appearance of the child suggested what the Germans call "luft-hunger." The pulse was rapid and thready, but not irregular. The mind was perfectly clear. The mother drew my attention to a condition which I had never seen before; the whole left leg from the knee to the toes was of a dark, uniform, blue-black color; the right thigh in its entire circumference, from the knee to the groin, was of the same dark hue; a purpuric patch about the size of a silver quarter of a dollar was also seen on the outer side of the middle of the right leg. The skin felt cold and slightly infiltrated in the purpuric areas. The

hæmorrhages must have been enormous as not a patch of normal skin was visible in the whole extent of surface described. The conditions indicated that gangrene must have supervened had the child survived. The little one died forty-five minutes after it was seen. No treatment was instituted other than a little whisky administered every few minutes.

A few days after the death of the child the following history was obtained from the mother: L. W., aged four years, American of German and English parentage. Surroundings hygienic, clothing and food good, nervous temperament, had never been a very robust child. During the night of Feb. 3d, he complained of feeling sick, shortly after this he vomited, a bowel movement quickly followed, a faint scarlet rash was observed on the trunk, the throat was slightly sore and the glands on both sides of the neck were somewhat enlarged; however, no subsequent desquamation followed, and at no time did he seem seriously ill, only very weak; he had not been confined to bed, but was dressed and allowed to play in a room. On the morning of the eleventh, while dressing him, the mother noticed that he was extremely pale and apparently very feeble, she also observed a patch of purpura, about the size of his own hand, on the outer side of his right thigh. Becoming alarmed at this discovery she sent for the doctor, who made light of it and told her to wrap the thigh in cloth saturated with sweet oil and lime water. The child was then dressed and brought down stairs and placed in a little chair, where he remained all day refusing to eat or play, but otherwise he did not complain. At ten a. m., while attending to the dressiug, the mother noticed that the patch on the thigh was increasing in size and that another one, about the size of a cent, had appeared on the outer side of the left leg. During the day these patches of purpura steadily increased in size until at nine p. m. they had covered the areas described. Slight epistaxis occurred in the afternoon, with this exception there were no hæmorrhages from any of the mucous membranes.

The character of the affection which preceded the purpura cannot, from the symptoms, be determined with any degree of certainty. This case occurred during the epidemic of influenza, a fact which must also be considered. It might be well to mention that two brothers of the child, aged respectively ten and thirteen years, had fever with sore throat, but no rash, during the period of the child's illness.

Case II. (Butler, *Buffalo Med. Jour.*, 1858–'59, xiv, 592.) A brawny eruption observed early in January between the shoulders. On January 15th, the same eruption, scarlet in appearance and inclined to bleed, appeared on the neck. On January 20th, large bruises were noticed on both sides of the head and occiput, these were attributed to a fall from the bed; however, closer inspection of the child revealed small purpuric spots on the extremities. No hæmorrhage from the mucous membranes. Death occurred on the fourth day after the discovery of the purpura. Autopsy revealed the kidneys congested but all the other organs anæmic.

Case III. (Zuelschaur, *Klin., Wchnsch., Berlin*, 1869, vi, 176.) Girl, aged two years of good health, whose surroundings were unhygienic and dwelling damp. Vomiting and diarrhœa suddenly set in after a few hours of restlessness and fever purpuric patches appeared simultaneously upon the face, back and nates; no hæmorrhages from the mucous membranes. Death in less than twenty-four hours.

Case IV. (*Ibid.*). Girl, two and a half years old of delicate health, whose surroundings where hygienic with the exception of a damp dwelling, and whose parents were healthy. She had suffered from three or four attacks of pneumonia since birth, and a bronchitis directly preceded the outbreak of purpura; she was taken sick suddenly at night with vomiting and purging. When she was seen at seven a. m. her face was extremely pale with a dark red patch on her chin; smaller spots were observed on her cheeks, neck, breast, back, abdomen, legs and thighs. Her pulse was rapid and her respiration hurried and gasping. No hæmorrhages from the mucous membranes. Death occurred at eleven a. m. of the same day.

Case V. (Appenrodt, *Med. Wchnsch.*, 1876, 11, 439.) Child, one year old, was attacked with gastro-enteritis on the fourteenth of August; purpuric spots were noticed on the twenty-fifth of August; these continued to appear until the fifth of September. No hæmorrhages from the mucous membranes. The child was extremely ill, but recovered in three weeks.

Case IV. (*Ibid.*). Child, nine months

old. Previous history; had whooping cough at two weeks of age, the disease ran its course in fifteen weeks and was followed by recovery. At nine months of age it was well nourished, although the mother stated that it suffered from "inward spasms." One day hæmorrhages suddenly occurred from the nose and stomach, these were quickly followed by the appearance of purpuric spots which rapidly spread over the trunk, extremities, pharynx and buccal mucous membrane. Death on the fourth day. Autopsy negative.

Case VII. (Ström, *Eira Göteborg*, 1887, xi, 136). A child, two and a half years old, was seized with purpura a few days after recovery from scarlatina. There was œdema of one leg with pain, bloody mucous discharge from the nose, albumen in urine, pulse weak. Gangrene of legs ensued and death occurred on the third day.

Case VIII. (Arctänder, *Hosp. Tid. Kjobenth*, 1887, 3 R. V. 227–229). Child, four years old. Purpura suddenly appeared on one leg, and then on the other one, it spread rapidly until large surfaces were covered; the legs were cold, swollen, and tender to the touch. Intense thirst and restlessness prevailed. Effusions of blood occurred into the superficial layers of the skin forming large bullæ. There were no hæmorrhages from the mucous membranes or albumen in the urine. Death on the third day of the disease. The character of the lesions before death indicated that gangrene would have supervened had the child lived.

Case IX. (Henoch, *Prag. Med. Wchnsch.*, 1886, iv.) Boy, five years old, was attacked Oct. 4th, by a frank pneumonia, which involved the base of the left lung. Ten days later he complained of pain in the left leg. This was quickly followed by the appearance of large and purpuric patches which rapidly increased in size and became confluent so that in a short time the whole body was of a blue black color. No hæmorrhages from the mucous membranes. Death in thirty-six hours.

Case X. (*Ibid.*). Girl, two and a half years old. A few weeks after recovery from scarlatina large purpuric patches suddenly appeared on her legs, they spread rapidly and became confluent so that in a few hours the whole body was a dark blue color, and large bullæ were seen on the surface. No hæmorrhages from the mucous membranes. Death in seven hours.

Case XI. (Jackson, *Archives of Pediatrics*, 1890, vii). Male, five years old, whose previous health and hygienic surroundings were good, had had a mild attack of measels in the latter part of May. On June 10th, he becames peevish and fretful and continued so until the thirteenth when small hæmorrhagic spots were observed on his back and extremities. Hæmorrhages suddenly occurred from the nose, stomach, bladder and bowels, which were so profuse that, to use the author's expression, the room was literally covered with blood. Death on the fourth day.

Case XII. (Collie, *Lancet*, London, 1891, 1). Male, aged nine years. Three weeks after an attack of scarlatina large purpuric spots appeared on arms and legs, they continued to increase in size until large surfaces were involved. The face was pale and pinched, the mind clear and distressed. No hæmorrhages from the mucous membranes. Death in forty-eight hours. Rigor-mortis marked. No hæmorrhagic patches found in any of the internal organs; there was intense anæmia of the heart, lungs, liver, spleen, intestines and kidney. The fluids in the ventricles of the brain, pericardium, pleura and peritoneum were clear. Hæmorrhages into the subcutaneous tissue only.

Case XIII. Herve, *Rev. Mens. de mal de l'enfance*, 1888, vi, 170–172.) Infant, three months old. Poor surroundings; peevish and fretful for twenty-four hours, when hæmorrhagic patches, the size of a dime, were observed on the abdomen and extremities, they rapidly increased in size and number. The face was pale and anxious, the respiration frequent and the pulse rapid. No hæmorrhages from the mucous membranes. Death in nine hours.

Case XIV. (Rinonapoli, *Archiv. itat. di pediat Napoli.*, vii. 92-95). Child, two and a half years old. A patch of purpura about the size of a quarter of a dollar, suddenly appeared below the left buttock after a short period of malaise. A closer examination revealed quite a number of petechiæ covering the surface of the body; they increased rapidly in size. No hæmorrhages from the mucous membranes. No sugar or albumen in the urine. Death on the third day.

Case XV. (Gibbons, *Med. Times and*

Gazette, London, 1885, 1. 2. 5.) Boy, three years old, suffered from chronic enteritis for one year previous to his death, and in consequence thereof had been kept on the most careful diet, when suddenly a large bruise appeared on the sacrum and on the inner side of each knee. No petechiæ present. A violent hæmorrhage from the stomach and a profuse epistaxis caused a fatal termination in a few hours. The mother discovered, just previous to the outbreak of purpura, that the cow, from which the child received its milk, had an abscess of the udder. The pus was noticed in the milk and the child was fed on other food.

Case XVI. (Lanneau, *New Orleans Med. and Surg. Jour.*, 1886, vii., N. S. xvi, 245, 249). Girl four years old, no prodromata. Purpuric spots first appeared on the leg, they rapidly increased in number until the body was covered. Severe pain was present. Bloody movements of bowels. No rise of temperature. Seriously ill for two weeks; recovery.

Case XVII. (Martin de Gimard, *France. Med.*, 1887, 11, 1557, 1569, 1581, 1593). Boy, eight years old. Purpura suddenly appeared without any initial symptoms. No hæmorrhage from the mucous membranes. Gangrene occurred in some portions of the body. Recovery after a protracted illness of months.

Case XVIII. (*Ibid.*). Boy, fourteen years old, had a severe hæmorrhage into the skin followed by gangrene. Death in four weeks. A micrococcus was obtained from pure cultures from the affected tissues of the body, which reproduced the disease in rabbits.

Case XIX. (Tizzoni and Giovannini, *Beitrage zur path. Anat. und Allgemeine Pathologie,* vi). Boy, aged four years, a strong, vigorous child had impetigo. On the tenth day of this disease he had a chill, his face became œdematous and a profuse hæmorrhage from one ear occurred. At the same time purpuric spots appeared upon the healthy skin and hæmorrhagic areas around the impetigo pustules. Urine deminished in amount, albumen and casts present. Hæmorrhages from the ears increased, and a blood tumor formed on the left side of the neck. Anorexia and vomiting. Death occurred on the fourteenth day after the appearance of the impetigo, and four days after the supervention of the purpura.

Case XX. (*Ibid.*). Girl, six years old, sister of the above case, slept in bed with her brother until three days before his death. Five days after the appearance of the disease in the brother, it manifested itself in the sister and spread rapidly; a week later she suffered from malaise which was followed by fever and successive chills; she vomited frequently and complained of pain in the epigastrium; her head, face, neck and hands were œdematous. Hæmorrhages occurred from her nose, ears, stomach and bowels, and a blood tumor appeared on the left side of her neck and upper part of her back. Death on the thirteenth day of the disease and on the fourth day after purpura showed itself.

It would be interesting to mention in connection with the above cases, that another child in the same family, a boy, nineteen months old, had impetigo a little later. The infections had been recognized by this time, and antiseptic washes and ointments fully used. Purpura did not supervene and the child convalesced rapidly.

Case XXI. (Hanot et Luzet, *Archiv. de Med. et d'Anat. Path.*, 1890, 11). A woman, near the end of her pregnancy, although she had been well up to that time, suddenly complained of trouble with her eyesight, and malaise. No attention was paid to this and she slept well the whole of the following night. Nevertheless, the next morning she quite unexpectedly became comatose, purpuric spots making their appearance at the same time. During the night following, her child was born dead, it was a full term baby and but little macerated. The mother died on the third day of the disease, without having regained consciousness. Autopsy on the mother, purpuric spots on the skin, confluent in some portions; heart pale, liver and spleen enlarged, more especially the liver, in which hæmorrhagic extravasations were also found, lungs and kidneys congested; uterus revealed nothing abnormal. On removing the skull cap, the dura mater was found intensely congested, also tense from the underlying liquid; the pia was also congested and its veins, gorged with blood; purulent liquid was discovered under the arachnoid. Brain adherent in patches to pia mater, no marked congestion of the brain substance present, however, there were three or four small clots of blood in each hemisphere. Autopsy on

the child: slight maceration, putrefaction not advanced, no purpuric patches on the skin. The fluids in the serous cavities were slightly tinged with blood without odor or flakes of fibrin. There were hæmorrhagic extravasations into the thymus, liver, heart, lungs and pleura. No lesions were observed in the spleen, stomach, intestines or peritoneum. The brain was soft and congested, no pus was present. A streptococcus was obtained from pure cultures from specimens taken from the mother and child which reproduced the disease in rabbits. Of late years investigations into the etiology of purpupa have been made by various French, German and Italian pathologists. Letzerich in a monograph (*Untersuchingen und Beobachtungen üeber die Aetiologie und die Kentnisse der Purpura*) and also in a subsequent paper (*Die Aetiologie und die Kentnisse der purpura nebst therapeutischen Bemerkungen. Zeitsch. fur Klin. Med., Leipzig, No. 5, W. O.*) gives most interesting results. This author has had six cases of purpura under his immediate care of which some recovered and some died. He succeeded in isolating a bacillus from pure cultures from these patients which when injected into rabbits caused purpura.

Letzerich divides purpura into acute, sub-acute and chronic forms. The inference is that by the acute he means the fulminant variety which is almost always fatal; sub-acute, purpura hæmorrhagica, which extends over a period of several weeks and which sometimes terminates in death but more often in recovery, and by chronic purpura, scorbutus, which several authors regard at the present day as purpura. While conducting his investigations Letzerich himself become infected with purpura in some unknown manner and had what he calls the sub-acute variety; he had three successive attacks all within one year each extending over a period of several weeks but each attack milder than the preceding one. During these attacks his liver increased rapidly in size and extended nearly to the crest of the ilium, a distinct enlargement of the spleen was noted. Hæmorrhages occurred from the pharynx, gums, nares, bronchial tubes and intestines. There were purpuric spots on the skin and buccal mucous membrane. He regards the liver as the breeding place of the bacilli on account of its enormous development. Blood obtained from the hæmorrhagic spots on the skin and buccal mucous membrane stained with methyl violet revealed the same bacillus obtained from the culture experiments. He also, in the three attacks from which he suffered, obtained pure cultures from the spots and reproduced purpura each time in rabbits. From the beginning to the end of an attack the bacillus does not always present the same morphological characters; he suggests that this may account for the various bacilli described by others investigators. He infers from his experiments that purpura in all its forms is due to this bacillus and that the different varieties of purpura depend upon the intensity of the poison and the resistance of the individual.

Very elaborate experiments have also been made in Bologna by Tizzoni und Giovannini (*Bakteriologische und experimentelle Untersuchungen ueber die hæmorhagischen Infection, Beitrage zur path. Anat. und Allgemeine Path.*, 1890). In their culture experiments from their cases of impetigo followed by purpura, they obtained the staphylococcus pyogenes aureus, a pus producing bacterium, and a bacillus that had not yet been described which reproduced the disease in the dog, rabbit and guinea pig but not in the pigeon or white mouse. In order to cause purpura in the animals mentioned the bacilli had to be injected into the subcutaneous tissue, no effect being produced when they were injected into the blood, stomach or serous cavities. They concluded that the children died of a mixed infection, impetigo upon which purpura supervened, the poison which produced the purpura finding its entrance into the system through the lesions produced by the impetigo.

Of the twenty cases reported six had no prodromata, one was preceded by malaise, two occurred during convalescence from pneumonia, three after attacks of scarlatina, one after measles, one after recovery from whooping cough, one during an attack of acute gastro-enteritis, one during the course of a chronic gastro-enteritis and two during attacks of impetigo. Three were followed by gangrene, of these two died and one recovered. Five cases were girls, eight were boys, and in seven the sex was not mentioned. Thirteen cases had hæmorrhages into the subcutaneous tissue only, seven had hæmorrhage both into the subcutaneous tissues and from the mucous

membranes. In three cases the hæmorrhages were most marked from the stomach, in two from the ear, in three from the bowels, and in the two from the nares, eleven of these cases died and three recovered.

INTESTINAL OBSTRUCTION.

By DR. S. N. WILEY,

NORRISTOWN, PA.

According to Dr. Hunter McGuire, "When a mechanical impediment to the passage of the contents of the bowel along the intestinal canal exists, the condition is known as intestinal obstruction."

The causes of this occurrence are numerous, the symptoms urgent, the diagnosis difficult, the treatment uncertain, and the termination, unless relieved by nature or art, speedily fatal. There is no class of cases to which the practitioner is called more important, or which demands on his part greater skill and judgment.

Most authorities agree in dividing the causes of obstruction of the bowels into two great classes—acute and chronic.

In acute cases the attack is sudden, the symptoms violent, and unless the cause is speedily removed, life ends in a few hours, or at most in a few days.

In chronic cases the causes act comparatively more slowly, the symptoms are chronic or less urgent, and the danger of death less imminent. In this class the cause is not uncommonly spontaneously relieved, and the individual restored to health without the aid of medicine or the surgeon's art. This result sometimes happens in apparently the most desperate cases.

This classification of acute and chronic obstruction is necessary for a proper clinical study of the subject, but it should be noted that in practice there will be found some cases which partake of many of the symptoms of both acute and chronic obstruction, making it difficult to determine to which division the class properly belongs. It may also occur that some, at first, well marked acute cases, subside and become chronic in character, also a chronic case sometimes changes its nature and becomes acute.

* Read before Montgomery Co. Medical Society, November 2, 1892.

As a rule the conditions which produce symptoms of acute obstruction are:

Congenital malformations.

Impaction of foreign bodies.

Twisting of the bowel—volvulus.

Internal strangulation by loops, bands, false membranes, diverticula, mesenteric pouches, slipping of a portion of the bowel into natural or unnatural openings, etc., and

Invagination.

And as a rule the causes which produce symptoms of chronic obstruction are:

Constipation and fæcal accumulation.

Stricture of the bowel.

Compression of the bowel from abdominal tumors.

Contraction of the bowel from inflammatory changes, often tuberculous.

The statement was recently made before the society of a neighboring county that cases of intestinal obstruction averaged one to each practitioner during a lifetime. But an examination of some statistics would seem to prove otherwise.

Leichtenstern—Ziemssen, vol. 8—shows that external hernia and malignant tumor being excluded one death from intestinal obstruction takes place in every 300 to 500 deaths from all causes in hospital practice.

Hilton Fagge has shown from an examination of the records of 4,000 autopsies in Guy's hospital that fifty-four, or about a quarter of one per cent. were cases of intestinal obstruction.

Heusner from his own investigations maintains that annually out of every 100,000 individuals from five to ten suffer from this affection, and that one to every 300 to 500 deaths is due to this cause.

According to the mortuary records of England an average of one death from this cause is seen in every 260. Brinton reports one death in every 280. His statement is based on 12,000 promiscuous autopsis.

According to these statistics one death, at least occurs in Norristown each year. This number does not seem large, yet if this one should be from the family of any one of us, it would still be too large.

The symptoms which characterize acute obstruction are generally of a most severe nature, they are more or less sudden in their appearance, and they bear a close resemblance to those which denote the existence of a strangulation in hernia. The

individual may be in the most perfect health at the moment of their occurrence, or he may have been more or less unwell, although still able to attend to his accustomed business. The disease is usually ushered in by a pain in a particular portion of the abdomen, of a sickening, griping, colicky character, and soon followed by a decided nausea, and a sense of constriction in the situation of the strangulation. Prostration is an early symptom. The vital powers are depressed, as if the system had received a violent shock. Great restlessness exists. The patient is in great agony, tosses about in bed, his thirst is intense, his mental distress is equally great, and if old enough he is conscious of his danger, and is anxious and despondent. The vomiting increases in frequency, and the ejected matter consisting at first simply of ingesta or of bile and mucus, at length becomes stercoraceous; the abdomen is sensitive, so much so that the slightest pressure is almost intolerable; the bowels are tympanitic and obstinately constipated, the lower limbs are retracted to take off the weight and pressure of the abdominal muscles, the pulse is small, frequent and wiry; the features are pinched; the extremities are cold; often the mind wanders; the suffering is intense. And unless relief is speedily procured the patient dies, either from exhaustion or mortification of the bowel. The period at which this event occurs varies. It may be a few hours, it never is beyond a few days.

In chronic obstruction the symptoms are much less violent, than those that mark an acute attack. Their development is gradual. The chief trouble at first is constipation, with rumbling noises and frequent eructations, disordered appetite, more or less torpor of the liver, and progressive failure of the strength. Colicky pains are occasionally experienced, defecation is performed with much difficulty, and is accompanied with straining and tenesmus. After the case has proceeded in this manner for a variable period, it gradually or suddenly assumes a more serious character, evidently depending upon the occurrence of inflammation, which never fails to mark the close of the affection, whatever may be the nature of the exciting cause. From this out the case rapidly assumes the form of an acute attack.

A consideration of external hernia, is of course, not included in this paper, but it is a rule as old as it is important—always to make a careful examination of the different points at which hernia may occur in every patient who presents symptoms of intestinal obstruction.

The diagnosis of intestinal obstruction is always determined with difficulty—except when it depends upon disease of the rectum low down, or some foreign body known to have been swallowed, but not passed. In almost all other cases it must of necessity be obscure.

In the limited scope of this paper I shall not attempt a differential diagnosis—but refer you to any of the many good works on surgery, in most of which are found some valuable diagnostic hints.

What shall we do when confronted with this most grave and dangerous affection—for grave and dangerous it is, as all who have seen it must testify. There are few conditions of the body which cause the practitioner more anxiety and embarrassment than cases of intestinal obstruction, and when the precise seat and nature of the occlusion is not known, the treatment is almost entirely empirical.

The distinction, however, between acute and chronic cases, or of acute supervening upon chronic symptoms, can almost always be made, and a patient investigation of the history of the case, the mode of invasion, and a rigid analysis of all the symptoms presented will generally enable the attendant to come to some positive conclusions as to the cause of the occlusion. One fact in the treatment which cannot be too strongly impressed upon the mind, is not to use purgatives and irritant enemeta, formerly so much in vogue—in the hope of forcing a passage through the occluded bowel.

The patient is urgently solicitous for medicine which will open his bowels, but the use of purgatives to overcome intestinal strangulation is as senseless and hurtful as when used to overcome the constipation of external strangulated hernia. These agents only add to the nausea, vomiting, pain and peristalsis. The latter is often violent enough already to render coils of the intestine visible, and with every paroxysm may be adding to the entanglement and impermeability.

It is said that cathartics in some instances have unlocked the bowel in intestinal obstruction; these cases must be

exceptional and many of them were probably functional and not structural in character.

The great medicinal remedy in intestinal obstruction is *opium*—in small and repeated doses. Its use arrests the vomiting, stops the pain, and quiets the violent movements of the bowels. Very often by it the intestine is preserved and the life of the patient saved. No special dose can be prescribed, it should be administered until vomiting ceases and the pain is under control. Small doses of morphia given hypodermically, and quickly repeated is the best plan of exhibiting it. If for any reason its hypodermic use is impracticable, it had better be given by the rectum, for if given by the stomach it is apt to be rejected, or if retained, absorption goes on slowly or not at all. Opium lessens the danger of death by collapse; it gives nature an opportunity to untwist the gut in volvulus, or to unroll it in intussusception, or to cut off the invaginated part in gangrene; and internal hernia, morbid adhesions, strangulation by bands of lymph, stricture and other forms of obstruction, it diminishes violent peristaltic action, postpones inflammatory infiltration, fixation of the strangulated portion and keeps the parts in better condition for operative interference, which in many cases affords the only hope of relief.

To carry it further than slight narcosis and arrest of the most painful symptoms is an abuse of the remedy. By such abuse the symptoms will be masked and both patient and physician deceived.

When obstruction is due to fæcal impaction, or spasm, the opium treatment is often indicated. Not infrequently after pain and vomiting are relieved and slight narcosis is kept up for some hours, the bowels relax and spontaneous evacuation takes place. If not, discharge of the contents of the bowel should be assisted by the administration of castor oil, or calomel and soda in divided doses, or repeated enemeta of warm water.

These agents should be used, however, as long as there is pain, tenderness of the belly, or any evidence of peritonitis; but the opium treatment should be continued until all signs of inflammation have disappeared.

The local application of ice to the abdomen has been recommended; it is claimed by some that the danger of general peritonitis is lessened, and that strangulation itself has disappeared under the use of cold. In some cases the local application of heat will give a grateful sense of relief to the sufferer.

Abdominal taxis or massage has been recommended. It has been attempted while the patient was in a warm bath or under the influence of chloroform; but when the cause and the nature and the site of the disease are unknown, this, in my judgment, is to say the least, a doubtful procedure.

The injection of large quantities of warm water into the bowels to overcome obstruction should never be omitted before resorting to operative interference. This plan has been known to succeed after other measures had failed. In place of water the bowel may be inflated with air—as has been done with hydrogen gas. Senn reports a number of cases of rectal inflation with hydrogen gas, with good results, and no ill effects either immediate or remote. Care should be excised in the introduction of water, air or gas, as rupture of the intestine has taken place following their use.

Very decided relief may be given by irrigation of the stomach, by removing the contents of the stomach and intestines above the obstruction, but the danger incident to the employment of such a temporizing measure in acute obstruction lies in the fact that too much valuable time is lost before a curative treatment is adopted.

Patients suffering from acute obstruction should abstain from taking either food or drink,—as digestion and absorption are almost if not completely suspended—and the accumulation of fluids in the stomach and above the obstruction cannot fail to aggravate the symptoms. It exhausts the patient's strength, by causing persistent retching and vomiting; it is one of the causes which produce distension of the intestine; it favors fermentation and putrefactive changes and causes violent peristaltic action.

In cases of acute obstruction of the bowels from bands of lymph, diverticula, internal hernia, slipping of a portion of the gut into some opening, or twisting, when the treatment suggested has been faithfully tried and fails, the abdomen should be laid open, the cause of the obstruction should be carefully searched for,

and if possible removed.

I have been criticised for saying at the last meeting of this society that the patient suffering from acute intestinal obstruction, after proper medicinal means had been used for forty-eight hours and failed, should never be allowed to go longer without operative interference. I find that the most recent and reliable authorities agree that this should be the rule, while many claim that a few hours, at most one day, may be spent in trying medical means. After that time if the patient is not relieved, the sooner abdominal section is resorted to the better the chance to save life.

Acute internal strangulation of the bowel has the same symptoms, course and termination that acute external hernia has. It demands the same treatment—removal of the cause of the constriction. Delay in performing the operation in the former is as certain to be followed by peritonitis, gangrene and death as in the latter, and the medical attendant who hesitates to open the abdomen—or have it done and an attempt made to remove the constriction in case of acute obstruction—after a fair trial and failure of medicinal means, is as culpable as the one who delays the operation of herniotomy for unrelieved strangulated hernia. Senn says: "To let a patient die of the consequences of a removable cause of obstruction without an operation is a reflection upon the advances of modern aggressive surgery. Even should spontaneous recovery take place, or recovery after medicinal treatment, this does not insure immunity from future attacks."

The individual whose case I reported at our last meeting has suffered three attacks since the first of this year, from each of which he has narrowly escaped with his life, and now lives in daily dread of a return of his old enemy. Another patient in Norristown is reported to me, who has suffered from four violent attacks. The fact that these patients recovered, in the past is no evidence that they will do so in the future; while the fact that they have suffered repeated attacks would seem to indicate that there is some structural change.

To my knowledge within the past month one patient died in our community, in which the autopsy showed that life could have been saved by an operation. Another died in which no autopsy was made, hence it can never be known but that this life, too, might have been saved by surgical means.

As to the dangers of operative interference, I think I am safe in saying that we shall hear to-day that the danger of opening the abdominal cavity under proper precautions is so slight that patients suffering from ovarian tumors are encouraged to have them removed as soon as their presence can be diagnosticated, at a time when the general health remains unimpaired. The mortality following abdominal section for acute intestinal obstruction will be reduced to that of other intra-peritoneal operations as soon as the importance of an early operation is recognized; before the patient's strength has been wasted by the disease, and before the parts involved in the operation have undergone irreparable structural changes.

A CASE OF OVARIAN PREGNANCY —LAPAROTOMY—CURE.

By EMORY LANPHEAR, M. D.,
SURGEON TO ALL SAINTS HOSPITAL, ETC., KANSAS CITY, MO.

Many a woman has gone to the grave with a diagnosis of "pelvic hæmatocele," "peritonitis," "pelvic cellulitis," etc., when the real cause of death was extra-uterine pregnancy. Fortunately we are rapidly coming to the conclusion that (1) extra-uterine pregnancy is quite frequent; (2) that it may be recognized in many cases; (3) that in modern surgical methods we have a comparatively safe cure. As for the question of "pelvic hæmatocele," from an observation of a number of cases, I am almost convinced that in nearly every instance the trouble is ruptured tubal pregnancy.

It is now pretty generally conceded that all fecundation takes place either in the tubes or on the surface of the ovary, and the wonder has been that ectopic gestation is as rare as generally believed. I do not think it is very rare—in fact, it is of quite common occurrence; but because of unfavorable environments, early death and abortion of the product of conception occur in a large proportion of cases.

Lawson Tait has claimed that all extra-uterine pregnancy is tubal; in opposition to this Franklin Townsend, of Albany, before the American Association of Obstet-

ricians and Gynæcologists, 1888, presented an elaborate essay (which met general approval), in which the assertion is made that "extra-uterine fœtation can and does occur either in the Fallopian tube (a frequent form), in the ovary, upon the ovary, or in the peritoneal cavity." That true ovarian pregnancy does take place is proven by the following case:

CASE.—Mrs. John W., age 42 years, patient of Dr. T. Brown, of Hamilton, Mo.; two children—one 18 years and one 14 years of age; pregnant four years ago, but miscarried at four months; never well since; menstruating too freely and suffering from retroversion. Last menstruation occurred the last of May, 1892; some symptoms of pregnancy. August 2, was taken with hæmorrhage from uterus, accompanied by excruciating pains in left ovarian region, the bleeding stopped, but pain continued, with great collapse, and the abdomen became distended to its limit. Temperature has ranged from 99½° to 102°. In the night of August 15, I first saw her and examined her under chloroform. The whole pelvis was filled with a boggy mass, the lower part of the abdomen very full and a lump the size of a large orange easily made out in the left ovarian region. I therefore felt convinced of the accuracy of Dr. Brown's diagnosis of ruptured tubal pregnancy, and advised operation. On the morning of August 16, assisted by Drs. T. Brown and W. T. Lindley, I made abdominal section, and removed about one and a half gallons of fluid and of clotted blood; the left ovary was found to be the seat of pregnancy, its tube being whole and unaffected save the fimbriated extremity was bound down to the broad ligament by inflammatory action; to the ovary the placental attachment was plainly made out, and in its ruptured envelop the dead fœtus. A clamp was applied, and the broad ligament transfixed and tied with catgut, the tube, remnants of ovary and the baby cut away. The abdomen was then thoroughly irrigated with boiled hot water to the amount of about eight gallons, and the abdomen closed with catgut sutures, without drainage, with the usual dressings. Six hours later the temperature had dropped two degrees and the patient was free from pain for the first time in many days; but little shock. August 20, she was reported as free from pain, sleeping well and appetite returning; temperature normal and pulse 80. Recovery was uneventful, she being allowed to sit up in bed on the tenth day and to walk a little by the sixteenth.

Examinations of the specimen showed conclusively that this was a true ovarian pregnancy, the tube being as perfect as any I have ever seen, save at its extremity, as already mentioned.

The treatment usually advised for extra-uterine pregnancy is electricity, if a diagnosis has been made prior to rupture of the enveloping structures, the idea being to destroy the vitality of the impregnated ovum and allow its abortion. This I do not believe to be good treatment, for whenever pregnancy is sufficiently advanced to allow even a provisional diagnosis, the mass is already so large that it can only remain, and remaining be a constant menace to the life of the patient; for no woman with such a foreign body in the pelvis can be for one moment free from danger. Fatal inflammation is likely to be set up at any time, even years afterwards. And if a wrong diagnosis has been made, incalculable mischief may be done by the electric current; whereas, as Wathen says, "We find nothing against the knife, except that it is a surgical operation. No case of death has ever been reported as due to the knife. If a mistake in diagnosis has been made, no harm has been done, as the disease, whatever it is, will require the knife anyway." And, I may add, if the condition happens to be such that nothing has to be removed, exploratory laparotomy is an almost absolutely safe operation in clean and skilled hands; I have opened many bellies for exploration, and have never seen a symptom follow to cause regret. So I will say that whenever ectopic pregnancy is suspected, laparotomy is indicated, and urgently.

All authorities unite in advising abdominal section whenever rupture has occurred. That the operation may be done even a week or two after the accident is proven by the case here reported. But as a rule it may be said the earlier the surgical interference the better.

Clinical Lectures.

OSTEOCLASIS.*

BY PROFESSOR GRATTAN, M. D.
DUBLIN, IRELAND.

Professor Grattan was introduced to the class by Professor Sayre who stated that the distinguished visitor while in New York had consented to give a surgical clinic illustrating the operation of his instrument known as the "Grattan Osteoclast." Professor Grattan exhibited an instrument devised by himself for the purpose of fracturing the bones, particularly of the lower extremities, without resorting to compound fracture by the chisel and mallet. Hitherto it has been the custom in operating for the cure of "bow-legs" to first make an incision exposing the bone and then by a chisel cut part way through the bone which is then, by the application of force, fractured. This operation is attended with many dangers. First, we have the evils attendant on a compound fracture; second, a liability to septic infection; and third, the possibility of a fat

*Delivered at Bellevue Hospital, New York City, under the service of Professor Lewis A. Sayre.

embolus resulting from disintegration of the bone medullary substance. The "Osteoclast" is intended to overcome all these dangers. By it the soft tissues are not opened, the periosteum of the bone is not ruptured and the medullary substance is not disturbed. In operation it is extremely simple and the bone can be broken at any point desired. The instrument consists of two smooth, curved, parallel rods bent so as to encircle one-half the limb. These rods or arms are so arranged that by a screw they may be separated or brought together at will. By their straight end they are inserted into a plate through the upper part of which works a powerful screw. This screw points toward the curved arms and when the instrument is in operation the end of the screw plays in a wedge-shaped piece of steel that is placed against that portion of the limb that is required to be fractured. It is thus seen that the limb is between the curved arms of the instrument on one side and the wedge of steel on the other, and that by the screw this wedge can be forcibly brought to bear upon the bone and thus fracture it. To illustrate the *modus operandi* of the instrument a patient was brought before the students for operation. The patient, a girl, was seventeen years of age and of robust health excepting a deformity of the left thigh. This deformity consisted of a curving of the femur in its lower third. It existed from childhood and as she progressed in age and stature the deformity became more pronounced. At the time of the operation this left leg, due to the curve in the femur, was bent outward at an angle of seventy degrees. The patient being anæsthetized the "osteoclast" was applied to the limb at the point of deformity. The wedge was screwed slowly against the limb until the operator felt that two or three more turns of the screw would fracture the bone and then by making these last turns very quickly the bone was broken. After the removal of the instrument it was seen that, although great force was required to effect the fracture, the integument was not injured, and that it left the limb in a condition of simple fracture. The leg was now put up in a plaster of Paris cast, and when shown in the clinic two weeks after, was in a perfectly healthy condition—the patient having suffered no constitutional disturbances whatever.

Communications.

CROUP, DIPHTHERIA AND SCARLET FEVER.*

By F. LEONHARDI, M. D.,
DRESDEN, GER.

(*Continued from page 772.*)

During the epidemics of diphtheria the inflammation seen on the posterior fauces resembles often closely that which is seen in the initial stage of scarlet fever, thus often leading to mistakes in diagnosis, or named by some angina scarlatina sine exanthemata. But since the true specific bacillus of diphtheria has been found by Klebs and Lœffler, which is never present in scarlet fever, (in this latter one finds only cocci or streptococci), such mistakes cannot occur in the practice of the scientific physician. The comparison of the two diseases, however, still presents interesting points for further study.

The author's experience of Scarlet Fever dates as far back as the epidemic in 1843 at Leipsic, where he treated in private practice twenty-four cases, three of these ending fatally. During the years 1847 to 1856 he again had a series of seventeen cases, with three deaths—these belonged to the poorer classes. In private practice 1847 to 1892 he had 114 cases with eleven deaths, aside from these there were 120 treated at the Polyclinic. These, however, cannot be studied in their entirety since there are some discrepancies in the history.

The mortality of scarlet fever varies with the severity and gravity of the epidemic. The incubative period Leonhardi was able to observe in four cases with perfect certainty during the years 1872, 1875, 1884, 1889, and noted in each that it was five days. Prof. Cerutti in his lectures on special pathology (1843) also gives five days, while others Strumpell, Ziemssen, Thomas, etc., place the time from four to seven days. The natural course of Scarlatina is sudden in its onset with high temperature, marked increase in pulse rate, painful deglutition, redness of the fauces; vomiting may be present; appearance of rash either at end of first day or beginning of second. Fever either stationary or some increase up to third day together with

*Abstracted and translated for MEDICAL AND SURGICAL REPORTER by Marie B. Werner, M. D.

deepening in color and extension of the rash. A beginning decline of the fever on the fourth day until it reaches normal on the eighth or ninth day, the redness also gradually disappears and desquamation begins.

The description of this fever is quite similar to that found in uncomplicated (epidemics) of diphtheria, also of tonsillitis not due to scarlet fever, and not infrequently like some cases of non-suppurative erysipelas. The author's observations have led him to believe that when the thermometer registers in the first days 40°C. or more in the axilla, it is found chiefly in patients who have kept their skins active, promoting evaporation and perspiration, and that it was continued during the exanthematous stage. In these cases the desquamation period was satisfactory and unaccompanied by renal disturbance, the urine showed no albumen at any time during the daily examinations extending over three weeks. If the fauces and tonsils at first showed some whitish deposit and the tongue was thickly coated, they all disappeared promptly after the fever began to abate, so that at the end of the first week, tongue, fauces and tonsils presented a clean surface.

The treatment consisted in promoting the activity of the skin, by giving plenty of weak acid lemonade and tea from the linden blossom with milk. If the fever was high the following mixture was ordered: Sod. nitricum, Sod. bicarbonat. aa 2.5 to 4 grms., Aq. 180, Syr. Althea 20 grms. S. A dessertspoonful every two hours. Also a gargle consisting of lukewarm water holding in solution a small quantity either of Potass. chlor. or Sod. bicarbon.

In order to aid in lowering the mortality of scarlet fever it becomes important to begin in early life to promote a healthy action of the skin by regular baths followed by cooler douches. Undue exposure of arms and legs in children does not aid in this, but will harden the skin and reduce its functional activity, and children dressed in this manner are just as susceptible to catarrhal inflammations or enlarged glands; and the usual diseases of childhood are just as severe as in those whose blood is warmer.

In the irregular forms of scarlet fever the author noticed: First; coincident with the onset of the high fever there was congestion of the brain, unconsciousness and convulsions. Second; in other cases in which the fever was not high at the beginning and unaccompanied by the above named manifestations, it remained high beyond the stated time and even increased with the appearance of subsequent brain symptoms. The skin was harsh and dry and clearly was the cause of the hyperæmia of the rete malpighii. The author feels certain that in connection with the arrested function of the skin we have the beginning of hyperæmia of the inner organs, notably the kidneys. Third: The dangers of throat complications; this does not embrace the ordinary sore throat of scarlet fever, but considers such cases in which the poison has entered the deeper structures. Symptoms of this can be seen as early as the fourth or fifth day—are diphtheritic in character, coagulated necrosed tissue, gangrene, extension of inflammation into posterior nares, and mucous membrane of the nose, eustachian tube, middle ear, accompanied with lymphatic infiltration, about the neck and lower part of the jaw, with possible suppuration, septicæmia and pyæmia.

Of the seventeen deaths seen among one hundred and fifty-five scarlet fever cases three occurred in from two to four days. In ten cases death occurred between the fourth to ninth day, preceded by congestion of the brain, unconsciousness and cardiac paralysis. Four died after the second week due to renal complications.

Leonhardi has never shared the opinion of those who believe in the possibility of a mixed infection of scarlet fever and diphtheria, basing this diagnosis entirely upon the grave throat symptoms which are sometimes present in scarlet fever. The resemblance of symptoms objective and subjective can be explained by the absorption of infectious poisonous matter of scarlet fever. The author states further that he believes the tonsils and follicles in the pharynx offer a pregnant soil for certain germs and that is one of the principal mediums for infection of scarlet fever and explains to him the fact that persons exposed to the fever and who have previously had the fever often suffer from a more or less severe angina scarlatinosa sine exanthemata. In 1843 he saw two such cases which presented the complete picture of diphtheria; norash was present; thisappeared after exposure to scarlet fever. The elder

child made an uninterrupted recovery the youngest suffered from dyspnœa on the fifth day and was relieved by an emetic, which aided in expelling many shreds and an entire cast of the uvula the child recovered after fifteen days' illness. There is no doubt that those doubtful cases can easily give to those so disposed a bona fide attack of scarlet fever and cites a case which occurred in 1889, a child of five years had not left the house for two weeks owing to a cold and in consequence not come in contact with any person outside the family, she was suddenly taken ill with scarlet fever, it was found that the father had began to suffer five days previously from tonsilitis accompanied three days with fever, no rash. The child passed through a severe attack of scarlet fever lasting twenty-one days.

High temperature, congestion of the brain, unconsciousness and convulsions appearing in the early stages were treated by the old practitioners by local bloodletting at the temples or back of the ears; five to ten centigrams of calomel every hour or two, cold applications to the head. This has found favor with Leonhardi, who also uses baths when indicated, but speaks with greater satisfaction of the results gained by inunctions.

Hydrotherapy may be considered of value in grave cases to combat the excessive dryness of the integumental coverings to prevent a thickening of the epidermis and a consequent lack of proper exhalations. The patient is placed in a bath of 22° to 26° R. for five to eight minutes, giving cooled douches at the end of bath, in grave nerve symptoms they can be repeated two or three times daily. To this can be added the inunctions of fats two or three times daily, which the author believes to have diminished the number of renal complications. Internal medication consisted of acid muriát. dil. one to two grms. to aq. 150 to 180 grms., liberal internal use of water mixed with lemon, apple or raspberry juices.

English physicians recommended as a specific, in 1820, carbonate of ammonia, adding to this some camphor in case of cardiac failure. This will be found quite useful. In acute hæmorrhagic nephritis with diminished and concentrated urine, Leonhardi recommends first two to ten centigrams of calomel every two hours, followed by liq. potass. acetat., tartrate of soda, seltser water, with lemon juice or white wine. Even in profuse secretion of urine with albuminuria the vegetable acids will be of value so long as the urine is of an acid reaction. The mineral acids should be used when the urine is alkaline in reaction. In cases of heart failure camphor, ammonium preparations and musk will be found useful.

The severe throat complications of scarlet fever are best treated by the repeated injections in the mouth of a solution of alum or borax with potass. chl. honeyof roses and water. In addition to the lemonade and linden blossom tea the following mixture has been of service, nitrite of soda, bicarbonate of soda aa 2-r grms. aq., mucilage of acacia or syr. althea 200 grms. The treatment followed since 1863 to date has proved successful in all but four of seventy-one cases. One death was due to convulsions occurring on the ninth day. The other three caseswere first seen on the fourth day of the eruptive stage. So convinced is Leonhardi of the utility of the repeated local washings by injections and their beneficial results that he feels certain that Heubner of Leipzig has attained the last good results mainly by the use of his hourly lukewarm boric acid injections, rather than by his three per cent. carbolized injections into the tonsils.

A CLINICAL DESCRIPTION OF DYSENTERY AS IT OCCURS IN NICARAGUA.*

By JUDSON DALAND, M. D.

Three varieties of dysentery are met with in Nicaragua, namely, the malarial, the endemic, and the epidemic, and of these the malarial is by far the most common. The prodromal symptoms of malarial dysentery are malaise, pain in the back, in the head, and in the umbilical region extending toward the pubes. In association with the diarrhœa these pains are highly characteristic of this form of dysentery. Mild cases are marked by very slight febrile and circulatory disturbances; whereas in the more severe cases, we have a moderate elevation of temperature, varying between 102° and 104° F. The stools are at first composed almost entirely of pure mucus, are small in

*Read before Phila. Co. Med. Soc., October 26, 1892.

quantity, and are frequently attended by tenesmus; soon the mucus is streaked with blood. The pains are not usually severe during the act of defecation, but the pain in the head and back is excruciating. Liver complication are not infrequent, particularly acute hepatitis or acute hepatic engorgement, each of which is frequently associated with jaundice. Hepatic abscess is a rare complication and is usually secondary to the ulceration of the colon. At times the spleen becomes greatly engorged.

Changes in the urine, indicative of kidney disease, probably exist, but chemical and microscopical examinations are rarely made from lack of proper instruments and reagents. Many of these cases of malarial dysentery are followed by intense anæmia and debility, lasting for several months.

When cases are seen early and promptly treated, the prognosis is almost uniformly favorable, but when seen late they usually die. As post-mortem examinations are never permitted, no information exists regarding the morbid anatomy or pathology of this interesting disease. The amœba coli, if searched for, would be found in many of these cases.

The treatment found most successful by Dr. Bermudez, of Managua, Nicaragua, is as follows: To an adult is given six grains of quinine morning and evening, in conjunction with—

℞ Ammonium chloride.....gr. v.
Pulv. ipecac.....gr. v.
Tr. opii.....gtt. x-xv.
To be repeated every two hours.

The amount of laudanum is determined by the severity of the pain. When the pain is particularly severe and obstinate, morphine is superadded, and, in cases marked by debility, it is customary to substitute the carbonate for the chloride of ammonium in five-grain doses, every two hours, day and night.

In the way of food nothing is permitted except milk or milk and lime-water, to which sago may be added. The patient is allowed to drink freely of cool water, thus alleviating the intense thirst which is usually present. Ice-water is considered harmful.

The *second* variety, known as endemic dysentery, resembles the preceding, but is very much milder, and is usually unattended by the fever or the severe pains in the head, back, extremities, or abdomen that characterize the malarial form. The stools are composed of fæces mixed with mucus and blood; are less frequent, and the tormina and tenesmus are less severe.

The average duration of malarial dysentery is three weeks, but occasionally it has been known to last two months, while very mild cases run their course in two weeks.

The treatment for this variety is the same as for the malarial, with the exception that the quinine is omitted. Almost all cases recover, and complication or sequelæ are uncommon.

The *third* variety recognized is called epidemic dysentery, which, as a rule, comes on suddenly, with pains in the head, back, throat, and extremities, accompanied with severe abdominal pains, shooting in character and centering at or about the umbilicus. Headache is particularly complained of; and not infrequently nausea and the vomiting of bile are associated. From the first the discharges are bloody, frequent, and there is intense pain and tenesmus. There may be as many as one hundred and fifty evacuations in the twenty-four hours, and an ordinary case may average twenty-four in the twenty-four hours, or one hourly, day and night. The temperature is high, ranging from 104° to 106° F., with a morning remission of two degrees, at which time there may be moderate perspiration. Severe cases die in less than seven days, and favorable cases may recover in from two to three weeks.

The discharges from the intestines continue bloody throughout the disease, but change in color, becoming dark and sometimes black from decomposed blood-pigment, and frequently they are vicid and tenacious from admixture with mucus.

At times the patient becomes delirious, and occasionally coma supervenes. Children often develop twitching of the muscles, rolling of the eyes, and there is a tendency to bury the head in the pillow.

The complications usually noted are hepatitis, jaundice, and abscess of the liver. Usually so soon as hepatic complications occur the patient dies; in other cases epidemic dysentery is complicated by croupous pneumonia with rusty sputum, and it usually affects the base of the right lung. Now and then severe internal hæmorrhages occur, and such an accident explains the cause of sudden death which has been occasionally observed. In this form of dysentery the anæmia and debility

are more marked than in the malarial form, and is more persistent. Not infrequently the patient suffers from obstinate constipation, due to stricture resulting from the healing of large and deep ulcers in the colon.

The cases are best treated by the administration of from ten to twenty grains of quinine given three times daily, and in addition chloride of ammonium, five grains; pulverized ipecac, five grains; and tincture of opium, ten to fifteen drops, repeated every two hours. Frequently, however, there is so much gastric irritability that these remedies are not retained, and in such cases the quinine is continued, but the chloride of ammonium and ipecac mixture is omitted, and fifteen grains of bismuth or five grains of tannic acid, repeated every two hours, is substituted. When opium is indicated it is invariably administered in the form of the tincture, in doses of five to fifteen drops, repeated every two or three hours according to the severity of the case. At times nitrate of silver, in doses of one-sixth or one-eight of a grain in pill form, is given every three hours. If the astringents mentioned prove of no avail, recourse is had to the acetate of lead, in doses of two or three grains every three hours. Most cases require stimulants, and experience has shown that alcohol in the form of brandy or whisky is *inadvisable,* and that the best results are secured from the use of sherry, port, or any of the red or white wines, associated with the carbonate of ammonium, in ten-grain doses repeated every three hours.

The food is restricted to milk and lime-water, sago, and farina. Not infrequently Dr. Bermudez has seen as many as one hundred cases in two months with the mortality of but 2 per cent., and his father would probably see as many as two-hundred cases in the same length of time.

Dysentery is one of the most common diseases of Nicaragua, and typical examples of the disease may be seen any day in the year. Most cases of malarial dysentery are observed during December, January, and February, while the epidemic variety occurs more frequently during the months of March April, and May. Of course, endemic dysentery is always present, and, as would be naturally expected, is equally prevalent at all seasons. The malarial form prevails chiefly in low, marshy districts, during the hot months. It is well to remember that the dry season, which corresponds to our summer, begins in November and ends in April, the remaining months constituting the Nicaraguan winter, or wet season. The average maximum temperature in the dry season is from 95 to 98 degrees. There is a difference of at least ten degrees between the temperature of the day and that of the evening.

The contagiousness of epidemic dysentery is fully recognized, and all ordinary precautions are taken to prevent the spread of the disease. Isolation, the free use of carbolic acid, the burial of all discharges, especially fæcal and urinary; the burning of the linen soiled by the discharges; and in cases where the patient is too poor to submit to the destruction of clothing by burning, they are disinfected by boiling water.

In all of these cases no researches have been made regarding the presence of the amœba coli.

Nicaragua has excited much interest of late, particularly in view of the probability that in the near future the Nicaraguan canal will become a reality, which will bring it into intimate relations with the entire world. I have, therefore, ventured to record these observations regarding a disease which prevails constantly, and at times becomes contagious.

My thanks are due to my friend and student, Dr. Salvador Bermudez, and to his father, who has practised in Nicaragua for more than thirty-five years, for the description of dysentery as it appears in Nicaragua, and for the treatment which has given them the best results. The enormous experience of the physicians of Nicaragua has heretofore never been made known to the medical profession, in so much as they have no medical magazine to which they could report their observations; and, moreover, at no time has it been their custom to carefully note the cases under their care; so that this report is of particular value, and is, perhaps, the first of the kind published in the English language. It is especially worthy of note, that the greatest confidence is placed in the use of the chloride of ammonium, and that this is their uniform practice. I would, therefore, suggest that it be employed in the United States, especially in the Southern States, where the climate more nearly resembles that of Nicaragua.

ACUTE CEREBRAL MENINGITIS SUBSEQUENT TO SPONTANEOUS ABORTION.*

By H. A. ARNOLD, M. D.,
ARDMORE, PA.

A single case offered as the basis of an article presented for your consideration must possess features that are profitable, or at least unique, in order to merit such presentation.

The following is offered in the hope that it possesses these distinguishing qualities:

Mrs. J. B., twenty-two years of age, married, the mother of two children, presented herself at my office in May, 1891, suffering from onychia.

There was the customary history of insufficient and impoverished blood, debility, and loss of appetite that we usually find in these cases.

Under a suitable regimen, and the use of tonic-alterative treatment of a ferruginous character, she recovered her health perfectly, and remained so until August 8th, when she was "unwell" for a day or two.

On the evening of Saturday, August 15th, she suddenly began flooding, went to bed, and remained there until 10 o'clock the next morning.

Feeling well all day Sunday, she attended to her accustomed household duties, and on Monday morning did the family washing.

At 3 o'clock P. M. (Monday the 17th), she began flooding alarmingly. She did not know she was pregnant, and could not have been more than one and a half or two months.

The word brought me by the messenger, not being of a definite character, I did not go directly to the house, and on my arrival I found a neighboring physician extracting the last fragments of placenta.

The patient was pulseless, bloodless and collapsed.

I speedily gave her tincture of digitalis, m. xx, hypodermically, also one fluid drachm by the mouth, in conjunction with port wine, the only stimulant at hand.

Immediately after a hot douching with plain water, the pulse, which had begun to make its appearance at the wrist, failed again; she became unconscious, and while so, vomited portions of an undigested dinner, the dejecta being principally sugar corn and tomatoes.

Two succeeding attacks of nausea and vomiting relieved the stomach of the remainder of the dinner, and, after administering hourly doses of tincture of digitalis, m. x., I left her at 9 o'clock, P. M.

18th. No rest last night. General condition fairly good considering yesterday's experience. Urine passed at noon to-day; circulation improving, but still quite weak at times.

19th. Good rest last night; general improvement; slight headache; kidneys acting perfectly.

20th. Did not rest so well last night, but says, she "feels well enough to get up," only her head swims a little. Slight pain in vertex and occiput. Tires soon of conversation. At 8 o'clock, P. M., word reached me that she had had two convulsions. I found her with hot head and dry skin. Learned she had complained of feeling cold, and had a chill, followed by fever. Soon after my arrival she had a third convulsion. The eyes were frightfully congested, face flushed, head rolling from side to side, considerable muscular twitching, particularly of the forearm and hand. At frequent intervals she would give utterance to the piercing brain-cry, so diagnostic of meningeal trouble. The pupils were widely dilated; the expression vacant, indicating obliviousness to her surroundings.

After a hypodermic injection of morphia sulphate, grain, one-half, I gave her twenty grains of chloral hydrate, and directed ten grains to be given every hour, while not sleeping. I left her, at 10.30, P. M., resting quietly. A few minutes later she was aroused by a neighbor, who called to inquire as to her condition, and the hourly dose of chloral was administered.

21st. 8 A. M. Little, or no, rest last night. Delirious this morning rolling-head—eyes terribly swollen and reddened, head fiery hot and congested, skin dry and hot, and has a yellowish, waxy appearance,—pulse rapid and thready,—all the blood she has is seemingly in the brain—brain-cry almost constant—no response to questions.

I discontinued the chloral. *She has*

*Read before Norristown County Medical Society, November 2, 1892.

taken 170 grains in 17 hours. Ordered opium, grain one-half every two or three hours according to condition; bromide of potash, grain j every hour; magnesia sulphate one heaped teaspoonful; quinia sulphate, grains two every three hours, and blisters behind the ears.

I also cut off her hair, which was very thick and long and ordered ice to the entire head continually.

At 5 P. M. she was somewhat quieter—head not so hot—no movement of bowels yet—no discharge per vaginum; yet no significance is to be attached to this fact, as the uterus had been *entirely* emptied, and made aseptic by suitable douches, and nothing during the progress of the case gave indication of any trouble from this source.

At 8 P. M. she went into a sound sleep which lasted all night.

22nd. 8.30 A. M. She awoke this morning with consciousness greatly restored; answers questions but has no recollection of the events of the last few days; she realizes loss of hair, also the presence of blisters behind the ears. Pupils are normal in size—face not so flushed—head not so hot—skin slightly moist; no movement of the bowels as yet, even by enemata.

She now entered upon a convalescence which ended in complete recovery.

Now, as to the points of interest. This woman lost so much blood that she was practically exsanguine. In this anæmic condition, meningeal complications, in the nature of increased vascularity, would scarcely be deemed possible; and would tend to undermine the belief in the efficacy of depletion by vivisection, or other methods of blood-letting, should they occur.

When a school-girl, this patient struck her head while playing in a culvert. Following this injury, for several years she had mild seizures, apparently epileptiform in character. There is no cicatrix, cranial elevation or depression discernible to indicate the seat of injury, yet it may have some bearing on the case.

On the 17th, 18th and 19th, there were repeated attacks of cardiac weakness, with an extremely weak radial pulse; and yet on the 20th and 21st she took 170 grains of chloral hydrate in seventeen hours. The investigators, and men who write books do not strongly impress upon us the value of chloral as a heart tonic; and the depression of heart and respiration occasioned by it, would, I suppose, have been a contra-indication to its use. Nevertheless, my patient survived, and on April 1, 1892, she had another miscarriage, when the only trouble encountered was headache and sensorial hyperasthesia, affecting principally sight and hearing.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated meeting, Nov. 9, 1892.

[ABSTRACTS.]

Dr. Anna M. Fullerton presented a paper on "Obstetric Surgery, with the Report of a Porro Case."

There is no subject connected with the science of medicine of which the average general practitioner has probably so little knowledge as that of pelvimetry, and the many deviations from the normal condition of things pertaining either to the maternal or fœtal economy which serve to render labor a pathological rather than a physiological process. The unquestioning relegation of childbirth to the field of nature by popular opinion curiously exercises its influence upon the professional mind; hence, we find that almost any physician dares to practice midwifery, although he may stand conscientiously aloof from the management of less critical conditions belonging to other specialties, as ophthalmology, otology, laryngology, or general surgery. In face of these facts, it is not surprising that we should have such statistics of maternal mortality as those reported by Dr. John Shaw, obstetric physician to the Northwest London Hospital, in a work written as late as 1890. "Insurance reports show," says Dr. Shaw, "that all of the deaths occurring in women between the ages of nineteen and twenty-nine, over 18 per cent. are due to puerperal causes, and of the deaths registered between the ages of twenty-nine and thirty-nine years, over 13 per cent. arise from the same source; in other words, all the other diseases and accidents to which women are liable at the earlier age, are less than five times as fatal as childbearing, and, at the later period, when the

activity of the function is waning, childbirth is still responsible for nearly a seventh of the total mortality arising from 'all the ills that flesh is heir to.' To these appalling numbers," he continues, "must be added the vast army whose lives are enfeebled and whose usefulness is crippled by some malady dating from the period of maternity." The injunction laid by beneficial associations in this country upon the payment of "sick benefits" to their members when suffering from what they denominate "womb disease," shows that from a business point of view pelvic disorders are far too numerous to make any investment based upon the chances of their occurrence or cure a possible means of gain. Whatever the sum she may have paid into the society, or however ill she may be, a woman suffering from pelvic disorder can claim no aid. This fact points a moral in itself.

Nor is injury to the mother the only disastrous result of ignorance and negligence in the management of labor. Too often, alas! in the subsequent history of the child, should it survive, we find evidences of brain injury: a slow or deficient mental development, actual idiocy, or congenital paralysis—conditions more pitiful than death and more to be dreaded. In an article read before this Society by Dr. J. Madison Taylor last spring, entitled "An Inquiry into the Causes Producing Cerebral Injuries in the Newborn," we have the frequency of such sequelæ referred to as follows: "Those of us who see many cases of nervous disease constantly have our hearts cruelly pained by parents who present children of defective and irreparable minds and bodies whose hurt has come through the process of birth." With regard to his investigations Dr. Taylor states: Questions directed to men of large obstetric experience result in a pretty uniform statment that more harm is done to the cerebrum of the fœtus by delays in the second stage of labor than by the use of instruments to expedite it. Neurologists also generally hold this view. In support of this statement he quotes from Dr. Abraham Jacobi and Dr. Egbert H. Grandin, of New York; Dr. Jaggard, of Chicago; Dr. Morton, of Ann Arbor; Dr. Barton Cooke Hirst, Dr. Wharton Sinkler, Dr. Joseph Price, and Dr. Edward P. Davis, of this city. Among those who believe that instrumental injuries exceed those resulting from prolonged labor he mentions Dr. William Goodell and Dr. George A. Rex, and expresses his own belief that instruments ignorantly and often unnecessarily employed are productive of serious consequences in a large proportion of cases. It is universally conceded that cases of congenital brain trouble do exist, and that the exciting cause may often be traced to an abnormal birth. The investigations of Sachs and Peterson, referred to by Dr. Taylor, show that in a table of 140 cases of paralysis, among 105 hemiplegias, 22 were found to be congenital; of 24 cases of diplegia, 20 were congenital; and so were 7, or possibly 8, of the 11 cases of paraplegia. This table of causes in the congenital cases showed that in 33 per cent. there was some difficulty in labor—simple delay or instrumental delivery.

When we look into causes of difficult or delayed labor, we find that, as a rule, it results from disproportion between the size of the child and the maternal passages, or from want of power on the part of the mother. The difficulties arising from malpresentations and other pathological conditions are closely associated with these.

A very much larger proportion of cases of difficult labor arise from pelvic abnormalities than is generally supposed. The lack of attention to the subject of pelvimetry in this country has led to the belief that American women are comparatively exempt from pelvic abnormalities. The graver grades of deformity are, to be sure, seldom met with; thus, the osteomalacial pelvis is not known in this country. The contractions and deformities due to rickets, however, are not at all uncommon, especially among the colored population. Prof. Anna E. Broomall, whose obstetric experience is probabiy one of the largest in the country, considers the most common abnormalities, taking the population as a whole, to be as follows: Among American-born women, the simple flat pelvis of the first grade of contraction, the average shortening of the antero-posterior diameter of the inlet being but 1. cm. below normal. The next most frequent cause of trouble she attributes to exaggerated inclination of the pelvis. Among the colored race the generally contracted rhachitic pelvis is most common, and the generally contracted flat pelvis the next in frequency. Dr. Edward Rey-

nolds, in his work on *Practical Midwifery*, just issued, states that in a recent analysis of the percentage of contracted pelves among the native- and foreign-born women of the out-patient department of of the Boston Lying-in Hospital, it was found that two out of every hundred American-born women showed some evidences of contraction, though it was usually slight; while among the foreign-born women of the clinic the proportion of deformity reached nearly 6 per cent. My own observations in connection with the maternity work of the Woman's Hospital vary somewhat from these figures, owing perhaps to the fact that we have in Philadelphia a larger proportion of foreigners than are found in the Eastern States. Among 1000 cases of labor of which I have had supervision since my connection with the Hospital about 14 per cent. had contracted pelves. If we include among abnormal pelves those of faulty inclination the number reaches fully 20 per cent. Careful measurements are taken of all the cases confined in the maternity wards. The generally contracted pelves were thus found to almost double the number of simple flat pelves, owing to the large proportion of negroes and foreign-born patients treated. In the simple flat pelvis the conjugata vera ranged between 8 and 10 cm. In the generally contracted between 5½ and 10 cm. The average contraction is not of a high grade.

The diversified conditions to which the various species of the human race have been subjected during their development have served to produce peculiarities in structure which have come to be regarded as characteristic. In the most intellectual races the pelvis is found to be most fully developed in area—a difference which must in part be associated with the greater size of the children's heads. The development is greater in the Circassian race, and affects especially the transverse diameter, which is lengthened, and the sacrovertebral angle thrown forward, owing, perhaps, to early burden-bearing, improper dress, and other vices of living. The simple flat pelvis thus results. In the more savage races, as Negroes, Hottentots, Bushmen, and Australian aborigines, not only is the size somewhat less, but the pelvic brim is more rounded because of the relative smallness of the transverse diameter, and thus shows a greater resemblance to the type of the monkey's pelvis, in which the antero-posterior diameter is greater than the transverse. The angle of the pelvic arch is also generally less. The comparative ease with which labor is accomplished among these nations, notwithstanding the smaller size of the pelvis, is due to the relative smallness in size and greater compressibility of the fœtal head. An exceedingly important factor in the labor is thus found to exist in the fœtal head. In his *Descent of Man*, Darwin tells us: "The belief that there exists in man some close relation between the size of the brain and the development of tne intellectual faculties is supported by the comparison of the skulls of savage and civilized races of ancient and modern people, and by the analogy of the whole vertebrate series." Dr. J. Barnard Davis has found by many careful measurements that the mean internal capacity of the skull in Europeans is 92.3 cubic inches; in Americans, 87.5 cubic inches; in Asiatics, 87.1 cubic inches; and in Australians, only 81.9 cubic inches. Professor Broca found that the nineteenth-century skulls from graves in Paris were larger than those from vaults of the twelfth century, and that the increased size, as ascertained by measurements, was exclusively in the frontal part of the skull—the seat of the intellectual faculties. One element of difficulty in labor, therefore, arises as the inevitable consequence of civilization, particularly when associated with the inactivity and luxurious habits of women of the higher classes—an undue development of the child, with increased ossification of the skull being the result of such habits. It is this resistance of the fœtal head, which increases with the age of the mother, that produces a history of increasingly difficult labors in a parturient whose earlier labors may have been perfectly normal. Such a history should at once direct attention to the measurement of the pelvis.

Ahlfeld's rule of determining the duration of pregnancy by obtaining the long diameter of the fœtal ovoid, by means of Baudelocque's callipers, one arm of the instrument resting just above the pubic symphysis, and the other over the fundus of the uterus, is that generally employed, especially as an aid to the determination of the period for the induction of premature labor, The measurement thus obtained is supposed to repre-

sent just one-half the length of the child in the extended position. The stage of development of the child may be thus determined, and the probable size of the diameters of its head. This rule is of necessity inaccurate, as the size of the developing child varies considerably in different cases at the same stage of gestation. It serves, however, as a working basis for approximating the size of the fœtal head. In the slighter grades of contraction, particularly in the simple flat pelvis, if the head be of normal size and compressibility, the labor may proceed according to the normal mechanism. If the size of the head be disproportionate to the grade of contraction of the pelvis, the mechanism in a flat pelvis is affected by the inability of the head to adapt itself to the inlet in the ordinary way, its efforts to engage in the transverse diameter, the extension of the head thus brought about by the action of the uterine forces combined with the resistance offered at the inlet, until the bi-temporal diameter, being brought into relation with the true conjugate, the head may clear the superior strait. The labor after this progresses rapidly as a rule, particularly in multiparæ, there being no obstruction in the canal. The main peculiarity in the mechanism lies in the long delay of the head at the pelvic brim. Another difficulty offered by this class of pelves arises from the fixation of the posterior portion of the head upon the promontory; the action of the uterine forces are then brought to bear upon the anterior, freer portion of the head, causing it to dip down into the pelvis. The planes of the head thus lose their normal relation to the planes of the pelvis, and an exaggerated obliquity is produced, which is one of the most common causes of impaction of the head in the pelvis. This obliquity cannot be prevented from occurring, because the fault lies in the pelvis. An attempt may be made to correct it manually, and at times may be successful. More frequently this condition, when recognized, is itself an indication for early extraction, because if left to itself the obliquity will increase, and the condition becomes more unmanageable. It is in the abnormal relations of the head to the pelvis thus brought about that, I believe, the greatest danger arises from the misuse of forceps. When the blades of the forceps are applied obliquely or transversely on the child's head, instead of on its sides, an acute and unequally distributed pressure results, to which, doubtless, many cases of cerebral palsy are due. In the flat rhachitic pelvis the reduction in the antero-posterior diameter is greater, hence this type of pelvis is more difficult to manage than the simple flat. The nearer the period of puberty the disease has occurred the greater the deformity produced. There is nothing in the appearance of the patient to call attention to the existence of the simple flat pelvis, unless there be considerable reduction in the antero-posterior diameter, when the abdomen of the gravida will be pendulous, and there will be greater mobility of the uterus because of the absence of fixation of the fœtal head at the beginning of labor.

Too great inclination of the pelvis likewise presents an obstruction to the engagement of the presenting part by carrying it beyond the area of the superior strait. Exaggerated obliquity of the fœtal head, together with other errors in presentation, position, and variety, are thus brought about. A tedious first stage of labor is the rule. Positional treatment will often enable this difficulty to be overcome without further aid. The accoucheur may assist the engagement of the head by flexing strongly the spinal column upon the pelvis. Manual pressure above the symphysis pubis, by which the presenting part is carried backward and more directly over the inlet, is also often successful in overcoming the difficulty. In the equally contracted pelvis extreme flexion is essential to the engagement of the head, and an actual occipital presentation is thus brought about through long-continued compression. The labor goes on as in normal mechanism, except that there is delay, slow engagement, slow descent, and slow explusion.

In the generally contracted flat pelvis the mechanism approaches that of the simple flat, but the labor is much prolonged. Engagement occurs in the transverse diameters.

The rate of maternal mortality in contracted pelves has been estimated at five per cent. and the fœtal twenty-one per cent. This probably represents the results when operative procedure is delayed.

The asymmetrical pelves of this country are the oblique ovate resulting from scoliosis, coxalgia, luxation of hip-joint, other injuries serving to shorten one limb

during the formative period of the pelvis. If the existing obliquity is but slight, the labor may not be affected, the only modification being its lengthening. In high grades of deformity, however, the prognosis is very grave—75 per cent. of the children being lost, according to one authority. The mortality of the mother is represented as about half this. If there be room enough in the pelvis, the induction of premature labor is indicated if the patient be seen in time. Thus, if the antero-posterior diameter of the inlet be 8 cm., labor may be induced about the eighth month. If the diameter is below this, abdominal delivery is indicated. In the management of labor the accoucheur must be observant of the earliest symptoms of exhaustion on the part of mother or child, and prompt in tendering the required assistance before it is too late.

Among the thousand cases of labor occurring in the service of the Woman's Hospital in the past six years, 19 per cent. required operative interference at full term. There were 8 deaths among the women delivered—less than 1 per cent. All but two of these were due to constitutional disease complicating pregnancy. Two sudden deaths occurred—one from shock following rupture of the uterus in a neglected transverse presentation; the other from air in the heart after a delivery, complicated by the pressure of a large fibroid. The fœtal mortality was 4 3-10 per cent. from all causes. In 40 cases in which contracted pelvis existed, labor was induced prematurely without the loss of a single mother or child, and thus the complications which might have resulted at full term were averted. Among the other operations performed were 79 forceps applications at the brim and in the upper portion of the pelvic canal, due to difficulty in descent of the head; 75 forceps applications at the floor of the pelvis for uterine inertia and rigidity of the soft tissues; 11 cases of podalic presentation required assistance in the delivery; and 4 craniotomies were performed, all on dead children. One Cæsarean section, one Porro operation, and one symphyseotomy were also done. Inclusive of the induced labors, the percentage of deliveries requiring artificial aid was 23.

The obstetrical resources for overcoming the mechanical obstacles afforded by moderate degrees of contraction are the induction of premature labor, craniotomy, forceps, version, and symphyseotomy, or pubeotomy. Undoubtedly the management, *par excellence*, of moderately contracted pelves is the induction of premature labor; but this necessitates a careful study of the patient's pelvis early in the pregnancy, in order that the time elected for the operation shall be most favorable to mother and child. The advantages of premature delivery to the mother are owing to the diminished head-pressure, hence, the rare occurrence of lesions of the genital canal. The disfavor with which the induction of premature labor has been heretofore regarded has probably been due to the large maternal mortality which attended its earlier performance, and which resulted, doubtless, from the employment of intra-uterine manipulations for its accomplishment and lack of antisepsis. The large fœtal mortality was due to insufficient knowledge of the needs of the premature infant and lack of care in its nursing. Spiegelberg gives the maternal mortality as 18.8 per cent., and the fœtal as 66 per cent. Among 30 cases in which I induced labor last year, there was no maternal or fœtal mortality. It is rarely necessary in this country to perform this operation before the thirty-fourth week for pelvic contraction. The only way of testing the value of induced labor is to compare the results of the latter with those of full-term labors in the same patient. With this view Dohrn reported 19 cases, with 41 children at term —37 of whom died. In 25 subsequent pregnancies in the same cases premature labor was induced, with 15 living children. Milne, in the *Edinburgh Med. Jour.*, vol. xix., reports six women as giving birth at term to 12 children, of which 11 were dead. In the succeeding 38 pregnancies of the same parents premature labor was induced, and 35 children were born living.

The aid of the couveuse—or hatching-cradle for infants—was very appreciable in the management of the premature infants born in our Maternity; and when, as in France, the use of the apparatus becomes more general, the induction of premature labor will, I believe, stand in higher favor in our own country.

The performance of version and extraction in contracted pelves exposes both mother and child to perils of no insignifi-

cant character. Borinski, collecting the statistics of version from the Breslau clinic, reports 58 cases in ordinary flattened pelves, with the result that just one-half the children were born dead. Three of the mothers died of results connected with the operation. In speaking of the high forceps operation, Professor William T. Lusk refers to the collected cases reported by Dr. Harold Williams. Among 119 cases, of the mothers nearly 40 per cent., and of the children over 60 per cent., perished. "So long as the head does not engage at the brim," says, Professor Lusk, "there is no rivalry between version and forceps. The latter should be placed under the ban as hardly less dangerous than the Cæsarean section." Version, however, is not applicable to the generally contracted pelvis; hence, in the revival of symphyseotomy we hope to find a method of procedure which will solve the difficult problem of non-fixation of the head in just such cases, and entirely do away with the barbarous practice of craniotomy on a living child. The operation is still in its probation in this country, but the brilliant results attained in Europe, as reported by Dr. Robert P. Harris, leads us to hope that we have in symphyseotomy an operation by which far less destruction to the maternal tissues shall result than can be claimed for either forceps or version, and by which, also, the injurious effects of pressure upon the fœtal head may be averted.

From the histories of reported cases, the chief objection to this operation, which lies in the possibility of non-union of the divided symphysis, would seem to be removed. In the only case of which I have any practical knowledge—that performed by Professor Anna E. Broomall, on Octo-10th, in our Maternity—the union is apparently perfect. Hubert, in a recent article in the *Archives de Tocologie*, warns us against the separation of the pelvic symphysis in mothers who are too old.

In cases of absolute pelvic contraction, where the congugata vera falls below 6.5 cm., and in the deformed pelves in which there is extreme narrowing, delivery by abdominal section is indicated. The two forms of operation usually resorted to are the Sänger modification of the classical Cæsarean section and the Porro-Müller amputation of the uterus. Two operations of this class have been performed in our Maternity wards during the past six years. The first was a Cæsarean section performed by Dr. Anna E. Broomall, on a patient with a generally contracted rhachitic pelvis, the congugata vera of which measured but 6.5 cm., or a little over two inches. The patient's childbearing history was as follows: Three children had been prematurely born, all of whom died. Her first labor at term was a forceps delivery; the second, a decapitation; the third, a craniotomy; the fourth, a forceps delivery, the child being lost; the fifth, a Cæsarean section. Both mother and child doing well after the section.

The second case of abdominal delivery was one performed by myself a little more than six weeks ago. The patient was a primipara, aged twenty-four years; four feet eleven inches in height; rhachitic, with marked kypho-scoliosis. Due to an old, unreduced dislocation of the left hip-joint, there was ankylosis with marked lateral obliquity of the pelvis and a beak-shaped pubic symphysis. The congugata vera was estimated at 7 cm. The patient was admitted to the Maternity wards of the hospital suffering with an acute bronchitis superimposed upon an attack of rheumatism. She was then in the latter part of the eighth month of pregnancy. When she had recovered from her illness, a consultation was held, and it was decided to deliver by abdominal section when the patient was nearer full term.

On September 26th I performed the operation assisted by Dr. Broomall, several other physicians being present by invitation. The nature of the operation had been explained to the patient's friends as well as to herself, and it was left to them to decide as to whether the uterus should be removed or not after delivery. My own feeling was strongly in favor of the uterine amputation, as it seemed to me totally unnecessary to preserve the childbearing function in a woman incapable probably of bearing healthy children, and bearing them, at any rate, at such risk. The parties concerned agreed with me in the matter, and the Porro operation was done. The uterus was lifted out of the abdomen before the uterine incision was made, and the rubber cord applied, as usual, for the control of hæmorrhage. Very little blood was lost. No fluid entered the peritoneal cavity. The child gasped as soon as delivered and

was soon crying quite vigorously. The uterus contracted firmly as soon as emptied. Before the delivery of the child, hæmorrhage was controlled by Dr. Broomall grasping her hands around the neck of of the uterus; after the delivery the rubber cord which had been placed was tightened. The placenta was delivered and the uterus cut away, after the application of a wire ligature. The stump was secured in the lower angle of the abdominal wound. I strongly desired to follow the method suggested by Dr. Baer, of ligating the uterine arteries and dropping the stump, but not having the same familiarity with this method as with the original one of clamping it, I refrained from running any risk. The mother made an excellent recovery and is perfectly well to-day. The child, a girl weighing six and and a half pounds at birth, now weighing nearly nine pounds, and in good condition. The operation was done about a week before full term.

I am indebted to Dr. Harris for some data concerning the Porro operation which I append to this paper.

"The Porro-Cæsarean operation has been performed over four hundred times, since its introduction in 1876, sixteen years ago; and its fatality has gradually decreased up to the present time. If all of the cases were operated upon in good season, and by men of known skill, their fatality of result would no doubt be reduced to a very small precentage. As an evidence of this reduction, I have to state that there were in the year 1888, 29 operations, with 16 deaths, or 55 per cent.; and in 1890, 45, with only 7 deaths—a mortality of 15⅗ per cent.

"There are three modes of treating the stump, viz: 1st, the original one of clamping it and securing it in the lower angle of the abdominal wound; 2nd, of dropping in the stump, as in many cases of hysterectomy, after ligating the uterine arteries and suturing the peritoneum over the cut cervix; and, 3rd, of securing the stump prepared the same way, by stitching it into lower angle of the wound, peritoneum to peritoneum. The original method has the least risk, particularly when the subject is not in labor, or has been for a very short time. Many women were lost in the early days of dropping in the stump, as many as 13 having died out of the first 18; but in the perfecting of the method, 17 have been saved out of 20, a mortality of 15 per cent. This is the ideal operation with several skillful men who have had very good results, and it leaves the woman with a free abdominal wall and abundant space for bladder expansion after her recovery.

"The Porro operations of our own country have been largely confined to cases of obstruction by tumors, as operators have usually preferred the improved Cæsarean section in those of pelvic deformity for two reasons: 1st, the fatality has been much less here; and, 2nd, almost all of the patients are married women, and operators do not think proper to destroy their internal organs of generation. In the last six years there have been 18 Porro operations with 12 recoveries in the United States (against 63 improved Cæsarean operations with 43 recoveries), 1 only having died out of the last 12, and this woman had been seven days in labor; and had a placenta prævia. Of the last 12 Porro cases, 2 died: 1 was in a favorable condition prior to the operation, and the other was already septic. both operations appear to be reaching a much lower measure of fatality, their result depending more upon the condition of the woman at the time of the operation than on the choice of method. In European maternities in a large number of operations, that of Sänger has the advantage in their final results."

Dr. Mary Putnam Jacobi, of New York City, read a paper on "Urethral Irritation."

The causes of vesical and urethral irritation in women are both numerous and diverse. Gynæcologists constantly refer to the irritation which accompanies uterine lesions—either inflammations or displacements. Dr. Howard A. Kelly has called attention to the tenesmus and frequent micturition which may be excited by lesions of the ureters, and such tenesmus may, for a certain time, be the most salient symptom of a renal calculus. On the other hand, the distinguished Philadelphian gynæcologist, Dr. Wm. Goodell, has truly said, that "A nervous bladder is one of the earliest symptoms of a nervous brain; for nervousness means a deficient control of the higher nerve centers over the lower ones; the vesical irritability indicates a lack of brain-control." The following case excellently illustrates this remark:

It was that of an unmarried woman, about twenty-five years old, of a highly

nervous temperament. A year previous to consultation she had, together with a sister, opened an office for type-writing. The business responsibility was unfamiliar, the work often heavy, and the patient had become anxious, worried and excited over it. She did not, however, complain of but one symptom, namely, a frequent vesical tenesmus, recurring night and day. The passage of urine was free, but preceded and followed by an unbearable distress, apparently situated in the neck of the bladder. The urine was entirely normal in every respect, free from albumin, sugar, oxalates, or other sediment, inorganic or organic. The urethra was normal, and the bladder could be explored by the sound without causing any pain. There was no uterine disease. I should add that there were no definite hysterical symptoms, unless the irritability of the bladder be reckoned as hysterical. The patient was entirely cured by local faradization—one electrode being placed over the lumbar spine, the other over the bladder. A few applications were first made at my office, and immediately followed by diminution in the irritability of the bladder, and in the tenesmus. Then the patient procured a faradic battery for herself, and applied the current for about twenty minutes every night. Relief was speedily obtained, and a complete cure effected in a few weeks.

My recollection of the details of this case is incomplete, as it was observed by me a good many years ago, and I have not full notes. If the frequent and spasmodic contraction of the bladder be due to an over-excitation of the nerve centers of the lumbar spinal cord, and if this over-excitation be due to loss of cerebral inhibition, it is difficult to understand why the local application of the stimulating form of the electric current should have had so positively curative an effect. The explanation may be approximately referred to the general action of faradic electricity on hysterical peripheric neuroses—action which may almost be called specific—since it is exerted with success in all three forms, namely, hysterical paralysis, hysterical cramps, and hysterical paræsthesias.

Another case was that of a markedly hysterical woman, aged fifty years, and who had passed the menopause, but who was subject to profound analgesia of the lower extremities, so that a pin could be plunged into the flesh and buried to its head without causing the least pain. This patient was subject occasionally to acute attacks of vesical irritability, associated with great general nervousness and depression of spirits. Such an attack was promptly dissipated by the injection into the bladder of two grains of cocaine dissolved in an ounce of water.

A third case was chiefly remarkable for the long duration of a single symptom, for the limited extent of its causal lesion, and for the final success of the treatment. The patient was a West Indian creole lady, between fifty and sixty years old, a widow, who had never had any children, and had never suffered any uterine disease. She was remarkably short, had an old-standing lumbar scoliosis, and suffered often from the muscular pains of lithæmic indigestion. She consulted me for an annoying and constant sense of pressure at the bladder, or rather more externally, at the urethra, attended with a moderate frequency of micturition, but no alteration of the urine. Just before and after micturition the sense of pressure increased and became more painful. Fifteen years previous, to relieve this same symptom, the urethra had been forcibly dilated by Dr. Marion Sims, but the patient insisted that she had not been at all benefited by the operation.

No spasm and but little pain was caused by the introduction of the catheter; and dilatation of the urethra with an ordinary urethral speculum failed to reveal anything abnormal. I tried several plans of treatment upon the case, which were all quite unsuccessful, and the patient finally ceased attendance. About five years later, very much to my surprise, she returned with exactly the same complaint. On this occasion, thinking that this peculiar and limited morbid sensation might be a pure neurosis, I applied faradic electricity by means of a double electrode inserted into the urethra and just within the bladder. This treatment at once greatly relieved the patient, and the relief persisted for twenty-four hours, when the distress returned. Repetition of the local electrization had the same effect, and the patient was so much more improved by this treatment than by any other which had been tried, that she persisted in it for several weeks. By that time she considered her-

self very decidedly improved, but not yet well. I had then an endoscopic examination made, and it was found that the mucous membrane of the bladder immediately surrounding the urethral orifice was swollen into a ring. The surface of the ring was moderately reddened. It seemed as if this protruding localized hypertrophy of the vesical mucosa had formed during efforts at bladder expulsion made in former years against some obstruction—very possibly a spasmodic contraction of the neck of the bladder in consequence of a fissure. The faradic electricity had relieved by determining retraction of the submucous cellular tissue. It seemed probable that the local application of a strong astringent would effect a more permanent shrinkage of the swollen mucosa. Accordingly, applications were made of solution of nitrate of silver—five grains to the ounce—by means of an instrument that permitted the application to be made exclusively to the affected locality. The result was immediately beneficial, and a few similar applications, made twice a week, succeeded in entirely curing this troublesome symptom, which had been annoying the patient for twenty years.

My fourth case seems to me of unusual interest, both on account of its medical history and of the physiological doctrine it illustrates. The patient is a woman of thirty-five years of age, who for many years had been overworked and underpaid in responsible business employments. Eight years ago her health began to fail, and in particular she began to suffer from two symptoms—severe spasmodic dysmenorrhœa and a distressing, burning sensation at the urethra. This was at first said to be constant, but inquiry showed that the patient suffered little from it while lying in bed, but intolerably if she attempted to walk, so that she soon became unable to walk a block or two. She consulted a prominent gynecologist, who treated her locally for three months, then advised her to enter the Woman's Hospital. She remained for some time in one service, and at length the surgeon declared that he could do nothing more for her unsess she would submit to the operation of lan artificial vesico-vaginal fistula. Refusing this, she entered another service in the same hospital, and here Emmet's button hole operation on the urethra was proposed and performed. The patient, however, did not benefit in the least from these various manipulations, but rather grew steadily worse. According to her statement the most careful exploration was repeatedly made for any pelvic lesion adjacent to the bladder which could explain the persistent distress, but nothing definite was ever found.

After ten months' of residence at the hospital the patient left it, rather worse than when she entered. She then went to England and consulted Dr. Keith, who, after a careful examination, advised her to desist from all further treatment. She followed this advice, and attempted to resume work, but her strength continued to deteriorate, and she finally was compelled to give up her work again, and remained a wretched invalid.

When the patient consulted me she was a thin, pale, anæmic woman, quiet and rather slow of speech—rather unusually free from the excitability and mobility which so often characterizes hysterical patients. Examination of her blood found 70 per cent. of hæmoglobin, and 1,960,000 blood corpuscles to the cubic millimetre. There was a continuous hum at the jugular.

The patellar tendon reflexes were normal. The subjective symptoms were: a constant sense of fatigue, mental and physical, rendering all exertion impossible; this associated with a sense of mental confusion and imperfect memory; distress, rather than pain, in the back of the head; profuse sweating at night; tenderness on pressure on Charcot's point, but on the right side; the skin over the hypogastrium and thighs moderately hyperæsthetic to touch, and extremely so to faradic electricity. There was a constant burning pain at the urethra, not at all aggravated by micturition, but greatly by walking. A distance of one or two blocks could be traversed with comparative ease, but then the burning pain became intense, a bearing-down sensation in hips and hypogastrium was added, and a heaviness extending down the thighs.

At menstruation the patient suffered intensely for several days, but during the pre-menstrual week she usually felt pretty well, at all events much better than at any other time. This fact contrasted emphatically with the pre-menstrual pains which almost invariably characterize ovarian disease. Again, micturition was neither

painful nor frequent, and was unaccompanied by tenesmus. A local examination found the uterus perfectly healthy; nothing abnormal discoverable in the pelvis except tenderness upon pressure in the region of the left ovary. The latter, however, was not sufficiently accessible to be exactly defined.

The urethra remained deformed by the partial failure of the union attempted after the button-hole operation. A catheter passed into the bladder caused no pain until it reached the neck of the bladder, then a spasm occurred, moderate in intensity but causing great pain. The spasm was easily overcome, and within the bladder the instrument caused no pain. The urine was normal in every respect. The patient had discovered for herself that the ingestion of large quantities of hot water —increasing the quantity of urine— diminished somewhat the urethral paræsthesia. If for any reason the urine became scanty, the burning became intense. The negative result of the local examination was entirely in accordance with that of the repeated explorations which had already been made by distinguished surgeons. In view of it, and of all the circumstances of the case, I myself made the diagnosis of a severe cerebro-spinal neurasthenia, of which the urethral burning, the ovaralgia, and the dysmenorrhœa were concomitant symptoms. They were, so I argued, symptoms projected on the periphery from a brain so badly nourished as to be the prey of sensory hallucinations, generated in its lower visceral centres. The history of the case seemed to indicate that local manipulation of the bladder tended to increase, rather than diminish, the subjective hyperæsthesia. The aggravation of the paræsthesia by walking, the relief afforded by recumbency, seemed to me to depend on the facile exhaustion of the centres in the lumbar cord, with their double relations to the innervation of locomotion, and to that of the pelvic viscera. It did not, as evidently had been supposed, argue a coarse lesion of these viscera, which might be aggravated by pressure; rather a vasomoter neurosis due to loss of spinal control when the lumbar cord centres became exhausted.

In a very large number of cases of cerebro-spinal neurasthenias, with irritative symptoms, depend upon lithæmia, or, more precisely, upon defects in the hepatic digestion of albuminous foods.

Reasoning most plausibly, though from too few experimental data, Haig has argued that many irritative or explosive symptoms in lithæmic cases depend on a saturation of the nervous tissues with uric acid; that the nerve explosions of migraine, and also of epilepsy, are correlated with a uric acid wave, as uræmic eclampsia is believed to depend on the surcharge of the brain tissues with excrementitious substances.

Herter, of New York (*N. Y. Med. Journal*, 1892), in a recent essay, calls attention to the numerous putrefactive products of nitrogenous foods, which form in the intestine when digestion of such foods is imperfect. Estimating these putrefactive products by the ethereal sulphates which appear in the urine, Herter has studied their relation to epileptic attacks, and believes to have found some degree of correlation between the formation of such substances and the convulsive seizures, and at any rate an abnormal degree of intestinal putrefaction in epileptic neurotics. These recent researches tend to focus and accentuate the conviction which many observant physicians must have formed, that the irritative phenomena of neurasthenic conditions are probably traceable to the immediate action on nerve centres of toxic substances circulating in the blood.

It is known that the forms of neurasthenia which are characterized by mere simple debility, are often wonderfully benefited by an excessive meat diet. This determines an excess of nitrogenous metabolism which, when well borne, is a most powerful stimulant to the nutritive processes of nerve centres. In irritative neurasthenias, however, the milk diet is often far better tolerated, and the explanation is probably to be found in the fact that on such diet the various perversions of nitrogenous metabolism are reduced to a minimum.

In the case in question I resolved to experiment with both diets, and began with the meat, intending to administer a pound and a half a day. However, in the first two days the patient only succeeded in in taking three-quarters of a pound a day, and on the third came to me in a very curious condition. Her habitual air of quiet depression had changed to great restlessness. Her respirations were 28, somewhat panting; her pulse 120, feeble, the

sphygmograph showing a marked respiratory curve. Her mouth was parched, she felt feverish, but, though she had continued to drink a great deal of hot water, the urine had become scanty and high-colored, and the urethral burning was intense. She had been unable to sleep the previous night, was nauseated, and had contracted an intense repugnance to even the thought of animal food. In spite of the restlessness the patient was drowsy. This condition, produced as promptly and distinctly as if in a laboratory experiment, suggested several explanations, and, unfortunately, there was no opportunity to analyze the urine in such a way as might aid in the choice between them. Thus there was the possibility of a uric acid saturation of the nerve centres, an improbable theory, as the symptoms were quite different from those habitually associated with uric acid excess or retention.

The drowsiness especially suggested that peptones, sufficiently modified in the liver, had passed almost unchanged into the circulation, as in Lauder Brunton's experiment.

From a third point of view, the imperfect digestion of the meat had resulted in abnormal putrefaction in the intestine with generation of toxic substances, which, passing into the blood, had occasioned the entire cortége of pseudo-febrile symptons. This, on the whole, seemed the most plausible hypothesis.

The most important practical fact was the great aggravation of the urethral burning or paræsthesia under these circumstances, which certainly tended to confirm my hypothesis of its origin in constitutional conditions. The diet was changed to one exclusively of milk, three quarts a day. Two days later the patient returned, seeming a different person. The restlessness, hurried respiration, and nausea were gone; the pulse dropped to 84, the urethral burning and ovaralgia disappeared, the patient feeling for the time quite comfortable.

The case is still under observation and the symptoms oscillate, although with, on the whole, a steady improvement in the condition of the patient. She is kept in bed the greater part of the day, on a diet of milk, baked apples, and a little rice; takes a steam leg-bath followed by cold sponging, minute doses of iron with maltine. Sleep is greatly improved, the mental depression lessened, the urethral burning reduced to a minimum, only occasionally aggravated; such an aggravation occurred on a cold, damp day, but on the next, a bright and clear day, the patient again felt a great deal better. Nevertheless, she was suffering rather more than usual from the occipital pain. This latter was entirely dissipated by an application of static electricity below the occiput. The same application was then made along the spinal column, and although for two minutes the patient was greatly fatigued, she then experienced an agreeable warm glow and sensation of prickling all over her body; and coincidently, what degree of urethral distress and ovaralgia was for the moment persisting, entirely disappeared.

Throughout that day and the next these two symptoms remained entirely absent, but the occipital headache returned on the second day, to again disappear on the third.

The absence of local pelvic lesions in this case might seem to render it inappropriate for presentation at this meeting. But I have thought it interesting because the existence of local symptoms seems to have been sufficient to convince so many distinguished physicians that such lesions must exist, even though they failed to discover them. Yet it is a general law for sensory symptoms that any one may be due to one of three conditions: There may be a structural lesion at the point to which the sensation is referred. There may be a lesion at a distant or adjacent point from which nerve irritation is irradiated to the point of sensation. Finally, there may be a functional disturbance of the brain nowise representing the part, which disturbance is expressed by the morbid sensation referred to the periphery. On this account there should not have been any difficulty in regarding this urethral symptom as an expression of central nervous disturbance, from the moment that careful examination had failed to detect any local lesion of the bladder, urethra, or adjacent pelvic organs. Yet the presumption in regard to such lesions was so great, that when they were not found, they were almost invented; and when prolonged surgical treatment only left the patient in a worse condition than at first, she was given up as incurable, because her parts refused to adjust themselves to a preconceived erroneous theory.

Medical and Surgical Reporter

ISSUED EVERY SATURDAY

ADDRESS:
Care P. O. Box 843, Philadelphia

PENFIELD BROS., Publishers.

Terms. Five dollars a year, strictly in advance, unless otherwise specifically agreed upon. Sent three months on trial for $1.00.

Remittances should be made payable only to the publishers, and when in sums of five dollars or less should be made by Postal Note, Money Order or Registered Letter.

NOTICE TO CONTRIBUTORS.

We are always glad to receive articles of value to the profession, and when used they will be paid for, or reprints supplied, as the author may elect. Where reprints are desired, writers are requested to make a note of that fact on the first page of the MS. It is well for contributors to enclose stamps for postage, that the articles may be returned if not found available.

THE MEDICAL AND SURGICAL REPORTER.

SATURDAY NOVEMBER, 26TH, 1892.

THE FUNCTIONS OF THE PERITONEUM.

Evidently the medical profession does not appreciate the importance of the peritoneum as a physiological factor in the human economy.

The idea prevails generally that this membrane serves merely as a lining for the abdominal cavity and an external covering for the vital organs within it; and that its complex folds and attachments are merely ingenious mechanical arrangements for supporting the various organs it covers. This is the anatomical view. Physiologists have failed to study its functions as thoroughly as those of other organs of the body, apparently satisfied with the anatomical view of the membrane and regarding its peculiar formation and arrangement, otherwise inexplicable, as the remains of something useful in lower forms of life, but of which the evolution of man has not as yet removed all traces. This, in spite of the persistent and invariable occurrence of these "traces" in the entire human race, and it was not until modern abdominal surgery forced an explanation of phenomena, that the peritoneum was recognized as being glandular in structure and function. This was some advance but does not explain all things.

Pathologically speaking, the entire profession is well aware of the enormous fatality of the diseases of the peritoneum, and it is only very recently that abdominal surgery has shown that peritonitis is not necessarily death. Ignorance on the subject certainly obtains when a prominent physician states before the Royal College of Physicians of London, that "the peritoneal structure has functions no doubt, but they are so unimportant or so obscure, that, however much they are disordered or suspended, no signs peculiar to the consequent disease can be discovered." Holding these views he is right in saying he cannot say "anything new to such an audience." If the views of his hearers are no further advanced that his own, it would seem a waste of time to recall to them facts, forgetting of which was a benefit. Doubtless his views can be considered conservative, as most of his study on the subject was evidently done in the mortuary.

His methods of study differ in every respect from those of an abdominal surgeon who has done as much as any to dissipate the unreasonable fear of touching the peritoneum and its contents. As a physiologist, Mr. Lawson Tait, does not have the pre-eminence he does as a surgeon, but the same characteristics that placed him at the head of abdominal surgery in Great Britain —the utter lack of reverence for professional idols; the prompt discarding of theories that would not fit conditions; the determination to exercise common sense in the study of his own material and to arrange and formulate his observations and draw con-

clusions in accord with facts; his frankness in acknowledging and correcting his own errors as he discovers them; and the enormous field of observation he has enjoyed —these characteristics require at least thoughtful consideration of any subject for which he is willing to be responsible.

Whether the deductions Mr. Tait has drawn from his own observation and experience—and his observations are made upon the living subject, not the cadaver, shall eventually be established wholly or in part, or whether further investigation shall show them utterly false, matters little. In furnishing a tenable, concrete working theory, he has done more than all that have gone before to advance the knowledge of what is, as he claims, an organ whose vital importance is second only to that of the brain. In a paper read before the Harveian Society of London, Mr. Tait re-presents in a collated form the observations published from time to time during a number of years preceding. The conclusions he arrives at are that the peritoneum has a glandular function "as all the great organs which are regarded as having functions preparatory to and essential to the general nutrition of the body, and most of these regarded as excretory, have this curiously-involved relation to this mysterious and complex membrane, with the doubtful exception of the pancreas. Further, the membrane itself has a series of strange and invariable plications and redundancies of surfaces, the omenta, mesenteries, and various appendices which, should its function be that of active secretion or absorption, clearly must be of great service. Then, finally, its surface everywhere is excessively vascular, hyperæmic, as it were; its minute anatomy shows abundant arrangement of stomata, like those on the leaves of a tree, eminently suggestive of active work of some kind. It is most profusely supplied by nerves which are not derived from the motor tract. Normally these nerves convey no sensation, and therefore it may be assumed that they are nerves for controlling or directing some special function."

In addition he said, "I have to point out that one great anatomical fact concerning the peritoneum has had, so far as I can discover, no kind of importance attached to it in its pathological consideration; in fact, it is not alluded to at all save in the anatomical text-books. It is that all the organs actively engaged in the primary preparation of the systemic nutrients are not only enclosed in the peritoneum, but all the blood gathered from these great organs is collected by a series of minute venous radicles exposed voluminously and immediately under the peritoneal epithelium to any influences which may arise in it. In addition to this, the whole of the blood prepared in or by these organs is mixed together in the portal vein and carried into the liver, where it undergoes its final change previous to the oxidation which seems essential for tissue nutrition everywhere.

In regard to the omentum he suggests "that it is the arbiter of the intra-peritoneal currents, there being an ebb and flow in the peritoneum. The great serous sac holds in it, like a dressing bag, a great mass of serous covered organs which may, any and all of them, secrete into its cavity, or absorb from it. Possibly they may carry out one process at one time and the other at another. The omentum, I think, does so certainly."

He believes that the cause of death in peritonitis is a "disturbance of the ebb and flow of the serum stream of the peritoneum and the disturbance of the function of the liver. In fact, the liver is the lethal organ in peritonitis." This is a very brief and incomplete statement of Mr. Tait's theory of the principal functions of the peritoneum and it furnishes a starting point for thorough investigation.

MARIE B. WERNER, M. D.

PHILADELPHIA, PA.

A. Bier, (*Archiv. f. Klinisch. Chirurg, bd.,* 43) describes an operation for the removal of bony sequestræ under the name of Osteoplastic Nekrotomie. This operation is, in the author's mind, especially adapted to necrosis of the tibia. His method of operation is as follows: He makes a transverse incision through skin down to and through the periosteum corresponding to the tuberosities of the tibia, beginning in the middle and extending to its inner surface. As soon as he has reached the crest of the tibia he leaves the periosteum, but extending the incision one finger's-breatdh beyond the crest through the soft parts only. A similar transverse incision is made two fingers above the ankle-joint. The inner ends of these incisions are united by a long incision, which extends down to the bone; at the point where the transverse incisions leave the crest, he splits the fascia transversely, the soft parts of the inner surface are pushed aside and half the thickness of the bone and periosteum of the inner tibial surface is split; a small saw is introduced through this cut and the bone sawed half through at the transverse incisions, the bone is then split in its long diameter with a chisel and lifted back—thus the tiba resembles a coffin with its lid thrown back, the sequestræ are of easy access the granulations and degenerated bone tissue can be removed with a sharp spoon; the various bone fistulæ treated (rividirt). After careful disinfection the flap is replaced, the soft parts united with sutures; or the cavity may be tamponed temporarily the wound being sutured secondarily.

The cavity remaining in the bone always fills with blood, especially if the tampons are not used—subsequent history usually shows that moderate suppuration is unavoidable. An attempt to use *Senn's* decalcified bone plates proved unsuccessful since they were usually discharged, often months after the operation.

Osteoplastic Necrotomie was performed thirteen times—eight on the tibia—one on the pelvis—one on the ulna, three on femur. The author, however, has concluded not to perform the operation on the femur again since he has found those bones nearer the surface more adapted for it.

In comparing results with the *Esmarch-Riedel* method in which more of the bony tissue is removed, leaving but a shallow cavity, into which the soft parts and skin are readily caught, or that of *Neuber*, which fastens the soft parts and skin into the bony cavity by means of sutures and nails; B. feels that these can only be used in cases where the disease is some distance from the epiphyses, and since they destroy so much of the bony tissue that they are less conservative and physiological than Osteoplastic Nekrotomie, this latter preserving more of the original bony contour, and at the time of operation permitting a radical removal of all diseased tissues. The time of healing also compares favorably with other radical operations—two—three months.

H. Kümmel *Centralb. f. Chirurg., No.* 42, 1892) reports three cases of retroflexed uterus which he corrected by operation in the following manner: He passes three sutures through the fundus, one of which he also passed through the periosteum of the symphysis the two lateral fortifying this in being placed so as to keep the uterus in immediate contact with the symphysis. K. regards this as an improvement on ventro-fixation, since union to the periosteum will be less apt to give than that to abdominal walls; but he also cautions that there may be some danger of the point of the needle breaking in the bone in taking the periosteal stitch.

One case upon whom he had performed this operation was confined 1½ years later. Labor was normal, six weeks after an examination showed the uterus still occupying its anterior position.

The other cases seemed to be doing well, respectively, 1½ and two years after operation.

Messner, of Wiesbaden, (*Centralb. f. Chir.*, 1892, No. 44) presents an interesting study in Asymmetry of the Thorax and contractions of the vertebral column following infantile paralysis. As an incentive to his studies he cites the case of a girl of 12 years, presenting marked scoliosis in the dorsal region and pronounced lordosis of the lumbar region;

* Translated for MED. AND SURG. REPORTER.

there is also a lack of development of the entire right side of the thorax, the defective condition extending upward to the right half of face and head; the arm and leg of same side are slightly atrophied. No absolute paralysis is present, though response to electrical stimulus is slow on the affected side. By extension the vertebral column can be entirely straightened. The early history of the child is interesting. She was well developed and healthy at birth; at nine months had convulsions, followed by some paralysis of the entire right side—this was, however, transient since she learned to walk at 18 months; there was no history of rachitis; and it was not until she was 7 years old that the parents noticed any deformity. A systematic course of treatment was not taken, and the disease was allowed to gain considerable headway. This case induced the author to study the early symptoms of scoliosis, especially in relation to infantile paralysis. An analysis of 156 cases of scoliosis showed that 8 had an unmistakable history of infantile paralysis. This group of cases is designated by Messner as Paralytic Scoliosis, and is distinguished from the rachitic form by the late or entire absence of fixation, whereas in the rachitic form fixation takes place early. This was ably demonstrated in the case reported, in that, there was no anchylosis or torsion of the vertebræ. Another noteworthy point was that the convexity of the cervix was always in the direction of the healthy side, while the paralyzed or paretic muscles were found on the concave side; this was of uniform occurrence in 7 of the 8 cases studied; the eighth being somewhat further advanced in paralysis. The electrical muscular tests were found to be of value in diagnosis, and sensation was not markedly impaired. The prognosis of this form of scoliosis is more favorable than that of rachitic origin. The author does not deny that there may be some advanced cases in which a cure would be out of the question.

Treatment consists in the use of electricity, cold sponge baths, and moderate massage.

In addition two indications must be met: 1. Support for the spinal column, this is accomplished by a properly adjusted corset. 2. Development of the muscles of the back, by gymnastics, massage, electricity, douches and out-door exercises. Of the 8 cases, 3 recovered completely, 4 were markedly improved; and although the 8th case was too far advanced to promise much, the author succeeded in placing the child on its feet after adjusting a plaster jacket, and extending from this a support for the hip joint.

Terillon, reports,in his eighth series, ovariotomies with one death 16 days after operation, due to chronic uræmia—both kidneys atrophic and sclerosed. He prefers asepsis to antisepsis. His experience after dropping the pedicle in cases where more than one ligature is necessary, in a thick pedicle, has been that up to the 25th or 30th day after operation convalescence progressed normally, after this time, however, there was fever accompanied by pain in the location of the stump, and examination showed a diffuse, painful swelling in the pelvis extending upward into the abdomen; the appetite was poor, and the patient became emaciated. After 2 or 3 months these symptoms gradually subsided and complete recovery took place. Suppuration or discharge of the ligature was never noticed. Terillon had this experience with 4 cases of this series, but is unable to explain the cause of evident inflammation. He feels that he can rule out infection, and thinks it may possibly be due to mortification (?) of the pedicle.

A. Brenner, contributes to the technique of gastro-enterostomy (*Wein. Klin. Woch.* 1892) two cases of inoperable carcinoma of the pylorus, in which he found it necessary to perform gastro-enterostomy. His method was the following: After making the incision he passed the right hand behind the colon in the region of the flexura-duodeno-jejunalis, pushing forward the great curvature of the meso-colon, and with this the ligamentum gastro-colicum; he then sutured these together with silk sutures, selecting a point in which there were present blood vessels. Making a vertical incision, between sutures he drew through it the upper loop of the jejunum. He united this loop of the jejunum with the anterior wall of the stomach, immediately above its greater curvation. The intestinal loops lay in their normal position while the transverse colon with its ligamentum gastro colicum was freely movable since the latter was situated close to the greater curvature.

One patient survived the operation, but died two months later, of carcinomatous cachexia, the second died 20 hours after the operation. This method recommends itself by the ease by which it can be performed.

Periscope.

THERAPEUTICS.

EFFECTS OF MEDICATED INHALATIONS.

Dr. A. Irsai, of Buda-Pesth, (*Lancet*), has made some instructive laboratory observations on the effects of the inhalations of various substances on the lungs and air-passages. Inhalation of air impregnated with the vapor of oleum terebinthinæ produced distinct pallor of the lung tissue, due, doubtless, to spasmodic contraction of the pulmonary capillaries. Oleum juniperi and oleum pini sylvestris produced similar results, but less in degree. Oleum eucalypti, oleum anisi, oleum menthæ and menthol, similarly inhaled, produced scarcely any change in the color of the lung-tissue. Creosote, thymol, and in a still greater degree guaiacol, produced redness, with great hyperæmia of the lungs. From these observations Dr. Irsai concludes that in acute catarrhal affections, with swelling, hyperæmia, and profuse secretions, those substances which produce anæmia of the lungs should be chosen, while in chronic torpid conditions, or in phthisis, where the supply of blood and the nutrition of portions of the lung are defective, substances which induce hyperæmia should be used. With any tendency to hæmorrhage creosote or guaiacol may prove dangerous.—*International Medical Magazine.*

SOMNAL.

Dr. Memmo (*La Riforma Medica*, No. 100, 1892) has given somnal in fifty-three cases seventy-five times, administering it in a syrup of oranges or peppermint:

℞ Syrup of peppermint, q. s.
Aquæ destillatæ..... gms. 100
(℥iijss).
Somnal..... gms. 2–5
gtts. xxx–℥jss).

Given to patients in the morning it produces a calm and restful day. When administered towards evening it quiets mental over-excitement (as in mania), alcoholic excitement and other psychoses, producing on an average a sleep of four to six hours' duration. No disturbance either of the digestive, circulatory or respiratory systems were observed, hence the remedy may be considered as innocuous. In many cases it was better tolerated than chloral, and in some better than sulfonal or tetranal. In women it exerts the same action, contrary to the assertions of Umpfenbach. It is very useful in insomnia due to hysteria, tuberculosis, and heart diseases in which there are no contra-indications It was also of service where all the hypnotics, as chloral, sulfonal and morphine, had been given without success. Only in rare cases was there observed, in the morning, a headache or vomiting—a very rare circumstance.—*Cincinnati Lancet-Clinic.*

POPULAR DELUSIONS ABOUT TONICS.

The Boston *Journal of Health* sounds the following warning on this subject which it would be well to heed:

Probably for no other class of remedies is there so great a demand as for those tonics that are commonly called appetizers. These are all more or less bitter, and are considered incapable of harm. As generally used, however, they do far more harm than good. They excite a feeling of hunger, it is true, but unless the doses are smaller than the layman unadvised is likely to take, they are sure not only to retard digestion, but to irritate the stomach and more or less upset the organs intimately associated with it.

He who feels that he needs an appetizer in the form of medicine, instead of buying tinctures, extracts, or other prepared solutions, will do well to obtain of a druggist one ounce of the dried herb, thoroughwort. This should be put in a pint of boiling water, allowed to stand for two hours, and then strained. After which it should be stored in an ice chest, or other cool place. The dose is two tablespoonfuls three or four times a day. Thoroughwort is one of the best of the simple bitters. and has a mild tonic effect, especially in dyspepsia and general debility.

The prepared drugs that are most often used as appetizers are the tinctures of gentian and colombo. These are generally combined, and to them is frequently added the syrup of ginger. Such preparations

are almost always taken in much too large doses, and instead of improving digestion they really impair its powers. Compared with thoroughwort their cost is very much greater; yet the herb tea has a better effect and when taken as advised is incapable of harm.

Of so-called strengthening tonics, quinine or some form of iron is generally resorted to by laymen. In certain conditions of the system these agents act well; but, without doubt, in nine cases out of ten in which they are used they are not needed; and not infrequently they do harm. It is a positive fact that there is not a single tonic in the way of medicines that a person could safely and wisely take unadvised, did he seek to recover lost strength.

Nor is there a tonic known to physicians that is likely to prove strengthening in a very large proportion of cases of debility. There are a variety of drugs that will stimulate and give a healthier tone to certain parts of the system, and, perhaps to the entire system, but as a rule they are very powerful, and a person who has not an intimate knowledge of them, their nature and effects, would be sure to injure, if not kill himself, were he to trifle with them. These agents only do in selected cases. Strychnia, for instance, might do one patient good, while another, presenting to the uninformed much the same symptoms, would be made much worse by it. The simplest of all the strengthening tonics is iron, and yet, contrary to the popular idea, this can only be used in a small proportion of cases of debility.

In a word, those persons who seek to regain lost strength by means of tonics, and without medical advice, must rely upon good, wholesome food, pure air, and judicious exercise; because, were they to trifle with drugs, not only would they gain nothing by it, but would be sure to do themselves very great harm, although by the way, they might not at the time recognize the harmful effects of the experiments.—*American Analyst.*

TREATMENT OF DIPHTHERIA.

Kohts and Asch report a large number of cures from the use of papoid in diphtheria. The former has treated several hundred cases with great success by the following method: Ten grains of the papoid are dissolved in half an ounce of water. This solution is painted on the diphtheritic membrane every fifteen or twenty minutes with a soft brush. The membrane disappears rapidly.—*National Med. Review.*

ANTIDOTES FOR POISONS.

USEFUL HINTS TO GIVE PATIENTS FOR EMERGENCIES.

In cases where the other articles to be used as antidotes are not in the house, give two tablespoonfuls made mustard in a pint of warm water. Also give large draughts of warm milk or water mixed with oil, butter, or lard. If possible, give as follows:

For Bed-Bug Poison Corrosive Sublimate, Blue Vitriol, Lead Water, Saltpetre, Sugar of Lead, Sulphate of Zinc Red Precipitate, Vermillion,	Give milk or white of eggs, large quantities.
For Fowler's Solution, White Precipitate, Arsenic,	Give prompt emetic of mustard and salt, tablespoon of each; follow with sweet oil, butter, or milk.
For Antimonial Wine, Tartar Emetic,	Drink warm water to encourage vomiting. If vomiting does not stop, give a grain of opium in water.
For Oil Vitriol, Aqua Fortis, Bi-carbonate Potassa Muriatic Acid, Oxalic Acid.	Magnesia or soap dissolved in water, every two minutes.
For Caustic Soda, Caustic Potash, Volatile Alkali,	Drink freely of water with vinegar or lemon juice in it.
For Carbolic Acid,	Give flour and water or glutinous drinks.
For Chloral Hydrate, Chloroform,	Pour cold water over the head and face, with artificial respiration, galvanic battery.
For Carbonate of Soda, Copperas, Cobalt,	Prompt emetics; soap or mucilaginous drinks.
For Laudanum, Morphine, Opium,	Strong coffee followed by ground mustard or grease in warm water to produce vomiting. Keep in motion
For Nitrate of Silver,	Give common salt in water.
For Strichnine, Tinct. Nux Vomica,	Emetic of mustard or sulphate of zinc, aided by warm water.

BEEF JUICE.

Where it is necessary to give an invalid just the juice of beef, broil say a half pound for just a moment over a quick fire, then score it thoroughly, put it in a lemon squeezer, and press the juice into a cup, add a grain of salt, stand the cup in hot water for a moment until the juice is warm and use it immediately. This is more tasty and appetizing than beef tea.—*Col. Med. Jour.*

MEDICINE.

HÆMORRHAGE FOLLOWING THE EXTRACTION OF TEETH.

A. A. Burns (*Amer. Jour. Dental. Sci.*) says:

After a tooth has been extracted, the blood comes spontaneously and flows for an unlimited time in a degree such as will not cause any alarm. Usually after five minutes flowing there is a process of clotting taking place. This stage in the flow of blood is called primary hæmorrhage, and is usually all that the surgeon has to deal with, as the blood generally stops flowing as soon as the clot is formed; but sometimes after the clot has formed, even eight or ten hours after, there appears a flow of blood more rapid than the preceding and in a somewhat pulsating manner. This is known as secondary hæmorrhage. When this occurs, it is first advisable to remove the clot which has formed in order that a more definite application may be made.

Take a strong solution of alum, formed by dissolving alum in warm water, and first applying with a syringe; after a few applications in this manner, pellets of cotton may be saturated with the solution and forced into the socket. Some think that a greater effect is produced by applying powdered alum to the pellet after saturation. This may make the action more powerful. However, if this is not effectual, it is well to repeat the treatment; or should we prefer another treatment of this, the wound may be syringed with peroxide of hydrogen, which is said to have an immediate action causing a clot which is not soluble in the blood. Pellets may also be saturated and inserted into wound.

If these methods are not successful, stronger styptics must be resorted to. The following are classed among the more powerful for local application: Nitrate of silver, tannic acid, subsulphate of iron, perchloride of iron, persulphate of iron, gallic acid, tincture of ergot. Care must be taken that no agent is employed as a styptic which will in any way destroy tissue.

Nitrate of silver may prove successful in some cases, but it causes destruction of the tissues with which it comes in contact, and also forms a clot which is soluble in blood. Perchloride of iron acts in much the same manner.

Persulphate of iron is the best of the iron compounds. It acts readily, does not destroy tissue, and after action presents a clean looking wound.

Tannic acid is an excellent styptic, and answers well in connection with a compress of lint or cotton. Also gallic acid. The clot formed by these is not soluble in blood.

TOOTHACHE.

Charles C. Crittenden (*Dental Review*) says: Toothache results from many different causes:

From irritation of living pulp due to sensitive dentine or full exposure; from congested pulp; from dead and putrescent pulp; from involvement of surrounding tissue from continuity and contiguity when poisonous gases in confinement force their way out of the roots.

Having located the trouble, it must be reached and fully discovered, to know its true character. It may prove a mere surface of inflamed dentine, with no real pulp involvement, in which case simply cleansing, stimulating with eugenol or creosote and then perfectly covering with cement, will command the situation until you are ready to make a permanent filling—always first having allayed the pain. It may transpire that a cavity reaches very nearly to the pulp chamber—so near that a turn of an excavator would expose the pulp. Then comes in play your best judgment as to what to do. The age, health, etc., of patient, general conditions of mouth and teeth are all to be considered. It is always best to make haste slowly though and do nothing you cannot undo. The first thing to accomplish is relief from pain. In this case, as in that of full exposure with hæmorrhage from pulp, a careful removal of débris, cleansing and drying of the cavity and application of a pledget of cotton dipped in eugenol and then touched in iodoform crystals and acetate of morphia powder, the whole placed in actual contact and sealed with bibulous paper saturated with sandaric varnish or chloropercha without pressure, will bring your patient back next day happy and relieved, ready for what you may deem best to do further. Quick thermal changes are excellent helps in finding out "what's the

matter." If colder temperature produces quick pain, the pulp is surely in full life, and the above mentioned conditions and course of treatment are indicated.

If, on the other hand, cold produces relief, and heat a welling-up or paroxysmal pain, you will diagnose at once a congested pulp, that is, one where the application of heat induces an increased flow of arterial blood into the pulp tissue which the capillaries are unable to handle and return promptly. This pressure of engorgement produces paroxysmal pain, which will be relieved by quick wounding and bleeding of pulp, followed by the same dressing mentioned above. A stage further on, you will find—especially in teeth of more than one root—a portion of the pulp converted into pus, which, on uncovering and venting, will often enable you to *see* the heart pulsation welling through the opening of chamber, thus showing that a portion of the pulp further up the canals is still living. Depletion, cleansing and the same dressing before mentioned means relief to your patient. By the term *cleansing*, I mean the free use of $H_2 O_2$ with the Dunn syringe.

NEURALGIA.

For six months a lady, at frequent intervals, had terrible neuralgia of the shoulder, going down to the forearm. I asked her if her teeth had been examined, and she said that they had never been suspected by her physician as the cause of the trouble. I found under the free margin of the gum, on the buccal side of the wisdom-tooth, a cavity that penetrated to the pulp chamber. It was such a difficult place to get at, and she had suffered so long, I advised her to have it out, and after the extraction of the tooth the neuralgia disappeared from the shoulder.

I have seen other cases of neuralgia where, apparently, a very slight thing caused it all. I remember one case of a patient suffering with intense neuralgia, where there were no cavities in the teeth, except what had been well filled, but there was a noticeable recession of the gums, which I decided was the cause, from their hyper-sensitiveness. The exposed parts of the teeth were treated with a little nitrate of silver, which removed the sensitiveness and also the neuralgia.—*Dr. Smith, in Int. Dent. Jour.*

THE BEST NUTRITIVE ENEMA.

Ewald, as a result of experiments, found that eggs, even though not peptonized, were to a considerable extent, absorbed by the rectal mucous membrane. According to the *Mercredi Medical* for April 1st, Huber, of Zurich, has recently repeated Ewald's experiments in Professor Eichorst's clinic, and announces that the absorption of raw eggs is greatly aided by the addition of common salt.

The salt is well borne, and causes, as a rule, no irritation of the bowel. He considers that eggs beaten up with salt, in the proportion of fifteen grains to each egg, are the best for nutritive enema. His method of procedure is as follows: Two or three eggs are taken, and thirty to forty-five grains of salt are added. They are slowly injected by means of a soft rubber tube, carried as high up the bowel as possible. Three such enemata are given daily. An hour before each enema the rectum is cleaned out by means of a large injection of warm water.—*N. Y. Med. Times.* October, 1892.

ORIGIN OF INSANITY.

The following are the conclusions of Dr. M. M. Buck (*Canad. Pract.*) on this subject:

1. All mental faculties arose each in its time, and they are of all ages, many of them being quite modern.

2. The date of birth of a faculty in the race may be judged by the age at which it appears in the individual, and its more or less universality in the race.

3. The stability of a faculty in the individual depends upon its age in the race; the older the faculty the more stable it is, and the less old the less stable.

4. Consequently the race whose evolution is the most rapid will be the most subject to breakdowns.

5. Those functions, in any given race whose evolution is the most rapid will be the most subject to breakdowns.

6. In the more progressive families of the Aryan race, the mental faculties have for some millenniums last past developed with great rapidity.

7. In this race the large number of mental breakdowns, commonly called insanity, are due to the rapid and recent evolution of those mental faculties.—*West. Med. Reporter.*

GYNECOLOGY.

ON PLUGGING THE CERVIX UTERI INSTEAD OF VAGINA IN UTERINE HÆMORRHAGE.

Plugging the cervical canal in cases of severe uterine hæmorrhage (other than postpartum) will be found more effectual and much more comfortable to the patient than the older method of plugging the vagina. The want of a simple means for completely filling the cervical canal has long been felt, but I think it will be found a simple matter by the use of an instrument constructed as follows: It is simply an improved form of sliding depositor, the difference being that, instead of the canula being pushed forward on the rod, the latter is made to retreat into the canula by the pressure of the fingers on projecting side-bars, and so the cotton plug dressing on the top of the rod is pushed home with certainty into the cervix. It may be urged that in cases of metrorrhagia or very early abortion a sponge-tent or sea-tangle would be an easier mode of treatment, and quite as effectual. But besides the inconvenience of having to place a tampon in the vagina as well, to insure retention of the tangle or sponge, we have also the great liability to sepsis, and I certainly prefer being on the safe side. The size of the os being determined by digital examination, a piece of absorbent cotton is to be neatly wound round the projecting point of the instrument for about two inches of its length, and thickly enough to fully fill the canal.

The cotton plug is then to be saturated with whatever antiseptic styptic the operator prefers—saturated solution of alum in glycerin, iodine tincture or turpentine; but I have a strong dislike for iron. A large-sized cylindrical speculum is then introduced and the os and cervix syringed with hot water, so as to wash away all clots. The cervix is then to be steadied with a tenaculum, held in the left hand, while the plug is passed into the cervix, with the depositor held in the right, as far as possible, and, on pressure being made on the side-bars while the thumb supports the base of the instrument, the plug is pushed off the rod and the depositor withdrawn. The whole operation can thus be done without assistance. If the plug has been made of the proper dimensions, which, of course, must depend on the judgment of the operator, and inserted fully into the cervical canal, there need be no anxiety as to the result, and the antiseptic and astringent action of turpentine, which I generally use myself, leaves nothing to be desired. The plug may be safely left till expelled by uterine action, when, if the hæmorrhage continue, the practitioner will be prepared to adopt other measures—washing out or curetting the uterus, or both. With a sponge-tent or sea-tangle in the womb it is always an anxious time for the practitioner, but with the plug properly in position he can take his own time about further interference. —Dr. Alex. Duke in *Satellite*.

PERIODIÇAL INTERMENSTRUAL PAIN.

In an article upon this subject (*Amer. Jour. Obstetrics*, October), Dr. Chauncey D. Palmer, of Cincinnati, Ohio, draws the following conclusions:

1. Periodical intermenstrual pain is a comparatively rare disease.
2. The disease is ovarian, not uterine.
3. This ovarian disease is an oöphoritis or peri-oöphoritis, or both.
4. The chief underlying exciting cause of these attacks of pain is the morbid obstruction to the extrusion of the contents of the Graafian follicles.
5. Many other morbid conditions, uterine, peri-uterine, or ovarian, may be associated with the oöphoritis or peri-oöphoritis, but their presence is not the cause of the essential symptoms.
6. Cure is effected only by overcoming the disease of the ovary or by its extirpation.

In regard to treatment he has found most benefit during the attack from the tincture of cannabis indica. Opiates he considers as objectionable here as in other forms of dysmenorrhœa. During the intervals reliance is to be placed on the most active so-called "alterative remedies;" mercuric bichloride, potassium iodide, ammonium chloride, and gold and sodium chloride, administered for a long time. The bromides are not to be ignored.

Local galvanization, with the anode to the vaginal vault, behind and to either side of the uterus, according to the ovary especially affected, occasionally changing to the secondary faradic current—the current of tension—has been of signal service to him.

Of course all manifest local disease, as well as errors of the general health, require attention, according to the kind and degree of the morbid complication. I have seen

good results following topical applications of ichthyolated boroglyceride. Counter-irritation before and during the periodical attacks of pain is sometimes efficacious.

Kreuznach waters, in Germany, so efficacious in the cure of some female pelvic diseases, would appear especially useful in this disease. We all recognize that a change of climate and scenery, with rest and its diversion, and massage, do as much in many of these conditions as the mineral waters themselves.

Finally, after a failure of medicinal and hygienic measures, faithfully tried, oöphorectomy is clearly indicated in bad cases. While oöphorectomy has been a greatly abused operation, particularly for many seeming reflex nervous diseases and for dysmenorrhœa, we are forced to accept the operation at times for this disease, but only as a last resort.

HYGIENE.

LIGHT IN THE SICK ROOM.

Dr. B. W. Richardson, in the course of a lecture on "Disease and How to Combat it," remarks:

A custom still prevails, despite all our sanitary teachings, that the occupants of a sick-room in the private house should be kept at all times in a darkened room. Not one time in ten do we enter a sick-room in the daytime to find it blessed with the light of the sun.

Almost invariably, before we can get a look at the face of the patient, we are obliged to request that the blinds be drawn up, in order than the rays of a much greater healer than the most able physician can over hope to be, may be admitted. Too often the compliance with this request reveals a condition of the room which, in the state of darkness, is almost inevitably one of disorder everywhere; foods, medicines, furniture, bedding, misplaced; dust, stray leavings in all directions.

In brief, there is nothing so bad as a dark sick-room. It is as if the attendants were expecting the death of the patient. And if the reason for it is asked, the answer is as inconsistent as the act. The reason usually offered is that the patient cannot bear the light; as though the light could not be cut off from the patient by a curtain or screen, and as though to darken one part of the room it were necessary to darken the whole of it. The real reason is an old superstitious practice, which once prevailed so intensely that the sick, suffering from the most terrible disease—smallpox, for instance—were shut up in darkness, their beds surrounded with red curtains during the whole of their illness. The red curtains are now pretty nearly given up, but the darkness is still credited with some mysterious curative virtue.

A more injurious practice really could not be maintained than that of darkness in a sick-room. It is not only that dirt and disorder are results of darkness—a great remedy is lost. Sunlight is the remedy lost, and the loss is momentous. Sunlight diffused through a room warms and clarifies the air; it has a direct influence on the minute organic poisons—a distinctive influence which is most precious—and it has a cheerful effect on the mind. The sick should never be gloomy, and in the presence of the light the shadows of gloom fly away. Happily, the hospital ward, notwithstanding its many defects—and it has many—is so far favored that it is blessed with the light of the sun whenever the sun shines. In private practice, the same remedy ought to be extended to the patients of the households, and the first words of the physician or surgeon on entering the dark sick-room should be the dying words of Goethe: "More light! more light!"—*The Druggist and Chemists' Gazette.*

DIGESTIBILITY OF BEEF AND FISH.

Popoff's researches on the digestibility of beef and fish after different methods of preparation show that both are more digestible in the raw state than when cooked. The longer beef is cooked, the more indigestible it becomes. After the same manner of preparations, except smoking, beef will, in general, be better digested than fish. Smoked fish is more digestible than raw or cooked. On the other hand, smoked beef is peptonized with more difficulty than if in some other condition, perhaps because the indigestion is impaired by the strong salting which precedes the smoking.—*Med. Review.*

THE SANITARY CONDITION OF CHICAGO.

"It is now well known abroad that Chicago is a pest-hole, and unless something is done mighty quick to improve matters, the expected millions at the World's Fair will fail to materialize, for, as the *Medi-*

cal Record puts it, 'people can find other and more pleasant means of suicide nearer home.'"

From the *Pacific Medical Journal* for August of this year, we take the above quotation. So many similar statements have appeared in different medical journals, that we feel it important to ascertain the exact state of affairs. With this end in view, we have requested the present, and the late, Secretaries of the Illinois State Board of Health to give us a statement, for publication, of the present sanitary condition of Chicago and of the sanitary measures proposed in view of the World's Fair.

We regret that both of these gentlemen found themselves too busy and too unwell to comply with our request.

We have, therefore, no reliable information on the subject, but, personally, we feel confident that the unparalleled energy, industry, good sense and intelligence of Chicago, will leave nothing undone that ought to be done to put the city in first-class sanitary condition.—*The Annals of Hygiene.*

OBSTETRICS.

QUININE AS A PARTURIFACIENT.

To strengthen uterine pains there is nothing comparable to the quinine sulphate in ten or fifteen grain doses which is always accessible and easily administered. In suitably chosen cases it never disappoints. Its characteristic effects may be observed an hour after administration, pain recurring more frequently and with progressively increasing power; fretfulness and despondency yielding to confidence and earnestness of effort on the part of the woman. Where the labor was complicated by placenta previa, dilatation of cervix was promptly achieved by a dose of quinine, permitting entrance of hand, and thus promoting speedy delivery. In other cases, after controlling convulsions occurring before term, where prior to eight months there is apt to be a lack of energy, quinine has taken the place of forceps, terminating labor without accident. In short, whenever in the second stage of labor the natural effort seems inefficient, pains weak and frequent, or moderate and infrequent, give without delay ten or fifteen grains of the salt, and nineteen times in twenty labor will be speedily brought to a close. In a practice of twenty years I have not had occasion to give a single dose of ergot before the expulsion of the after-birth, though for many years it has been my habit to administer a half drachm or a drachm afterward.

EFFECT OF ERGOT.

Dr. Meigs says: If an ergotic pain is produced to last thirty minutes, in a case where the placenta is on the fundus uteri, and to be jammed for thirty minutes against the child's breech, without an instant of relaxation, who can doubt that its circulation is either wholly or nearly abolished, and that when the child emerges at last from the mother's womb, it will emerge quite dead, or in a profound asphyxia from the long supression of its placental circulation? Multitudes of children are born dead from this very cause, by the imprudent exhibition of a medicine, *which as certainly excites spasm of the womb as nux vomica does of the other muscles of the body.*

THE IMPORTANCE OF EXAMINATION OF THE GENITAL TRACT DIRECTLY AFTER LABOR.

In a short paper sometime since I endeavored to point out the obvious advantage of flushing the uterine cavity with hot water directly after delivery, and my reason for adopting such a proceeding.

I now wish to draw attention to the still more important point of making a close examination of the genital tract for any injury which may occur (more especially in the primiparæ during the process of parturition) by both visual and tactile examination. The cervix uteri is frequently torn, the edges of the os lacerated, and the vaginal walls injured, leaving, perhaps, the perineum intact, and so the conclusion is oftentimes come to that "all is well," while considerable mischief may have taken place unobserved.

By the hot water flushing we get rid of several sources of danger, and, if a thorough examination is then made for vaginal or cervical injuries, it will be a comparatively easy matter, when such are found, to draw together the torn surfaces in severe lesions with catgut sutures, and cauterize the parts in minor ones with strong carbolic acid, thus leaving the parts concerned in a better condition for repair and less liable to absorb. It will be obvious that at no other time subsequent to

labor have we a better opportunity.

No objections will be raised by the patient, and acting on the proverb, "a stitch in time saves nine," may save her from septic absorption with all its train of untold misery.

The comfort to the conscientious practitioner's mind (when such lesions are found) by treating them at once is no small recommendation for the adoption of this proceeding, while the no less pleasurable disappointment of finding that none exist (and which could not have been determined without examination) will also commend itself. As a general rule, the uterus is not washed out directly after labor, nor any examination made, except of the perineum. The consequence is, that in many cases where septic symptoms develop, the true cause is never known, whether depending on a piece of membrane left to decompose in utero (which should have been removed by flushing before the binder was applied), or a lacerated cervix never discovered, or some tear in the vaginal surface, allowed, perhaps, for days subsequent to labor to absorb the morbid products of conception, and so, by permeating the patient's system, bid defiance to the best directed efforts of the practitioner. I am persuaded that in nine cases out of ten the septic symptoms in the lying-in patient are due to the causes I have pointed out in this paper. I may here allude to the danger (where no examination has been made of the genital canal) of endeavoring to combat the symptoms of septicæmia by syringing with corrosive sublimate solution, for should a torn or abraded surface exist (which, in my opinion, is almost a certainty) such surface, which, in the first instance, took up septic matter, is quite capable, as proved by some cases of severe burn treated with the corrosive solution, of absorbing it, and so contributing to, if not actually causing, the patient's death.—Duke, *Medical Press and Circular.*

VINUM IMPECACUANHÆ IN WEAK LABOR PAINS.

Stillmark (*St. Petersburger Medicinische Wochenschrift*, No. 10, 1892) contributes the notes of a case of uterine inertia in which the contractions were re-established by the administration of wine of ipecac. The patient was a IV-para, with a history of easy previous labors. Three weeks before the presumptive termination of her labor the membranes spontaneously ruptured, and one or two weak pains were experienced. The next morning Stillmark examined her and found head presenting in second position, os admitting two or three fingers. There were no pains. The patient was placed in a bath. Nine hours later, as the pains had not yet occurred, warm vaginal douches were applied without result. During the following night patient slept. Next morning, after a bath, warm vaginal irrigations were again used, and gentle massage to the uterus. As all this failed to establish the pains, wine of ipecac was administered in a fifteen-drop dose. Half an hour afterward the patient exclaimed that her abdomen felt hard. At 1.30 p. m., fifteen drops were again administered. In three quarters of an hour after the second dose strong normal pains began. In the evening the pains were weaker and about 10 o'clock had almost ceased. Five drops were now given, as some vomiting had occurred after the second dose. Energetic labor pains were soon established, and at 12 o'clock the child was delivered. The placenta followed.—*University Medical Magazine.*

NEWS AND MISCELLANY.

A SOURCE OF DANGER.

Confections of santonin, variously known as worm lozenges, worm troches, and worm confections, have been employed as domestic remedies for intestinal worms in children as far back as we can remember. It is a popular form of administering this well-known anthelmintic, and is resorted to by anxious mothers, without fear of untoward effects, just so soon as they have diagnosed "worms" to their own satisfaction. And when an accident happens, such as has been recorded recently, where a child two and a half years old is reported to have died from the effects of eating ten cents worth of the troches, it attracts but little attention, and the sale of the lethal confections goes on as briskly as before.

As found in the shops, the worm troche is a small cake of sugar, oval in shape, usually of a pinkish color and flavored with wintergreen. It cannot be easily distinguished from the ordinary confectioner's sweetmeat, and is altogether a very inviting-looking morsel. It is this inviting

appearance and the ease with which the troches may be procured by any person on demand which renders them such a source of danger. They are sold at the rate of ten cents per dozen, and when it is remembered that each troche contains exactly one-half grain of santonin, it will be readily understood how accidents may happen. Carelessness on the part of the child's guardians has been responsible for the majority of casualties reported from this source, and the child has in most instances been allowed to help itself to the toxic dose.

Some reform in the sale of domestic remedies of this description is evidently needed. The sale of santonin troches, in particular, should be restricted; and although a somewhat extreme measure, it would be in the interests of public safety to place santonin on the "poison schedule" and prohibit its *indiscriminate* sale in any form. In the meantime, it is to be hoped that druggists themselves will take sufficient interest in the matter to see to it that parcels of santonin troches are properly labeled before they are sent out.—*Pharmaceutical Record.*

RAILWAY SURGERY AT THE PAN-AMERICAN MEDICAL CONGRESS.

A Section of Railway Surgery of the Pan-American Medical Congress has been organized with Dr. C. W. P. Brock, of Richmond, Virginia, as Executive President. A full list of officers has been provided for each of the constituent countries. At the Eleventh Annual meeting of the Wabash Railway Surgical Association—the first organization of the kind—Dr. C. B. Stemen, of Fort Wayne, was by unanimous resolution requested to prepare a paper on "Organized Railway Surgery" and read the same before the Section on Railway Surgery of the Pan-American Medical Congress. At the same meeting Dr. Hal C. Wyman, of Detroit, offered the following which was unanimously adopted:

Resolved, That each member of this Association solicit his Congressman to interest himself in legislation in favor of the Pan-American Medical Congress.

EFFECT OF POSTURE ON HEALTH AND SYMMETRY,

In a paper devoted to this subject Dr. Eliza M. Mosher recapitulates as follows (Brooklyn *Med. Jour.*): There are three fundamental postures in which the body in the upright equilibrates. A certain amount of muscular force is required to retain it in any of these positions. The first posture is not practicable as an habitual one, because it does not admit of alternation in the use of the lower extremities. The second places the body in the most symmetrical attitude it can take, and at the same time permits the alternate use of its supports. This is a posture not naturally chosen, but easily acquired by training. The third, which is the favorite posture of mankind, is harmful in its tendencies, both as regards its influence upon the symmetry of the body, and the economic and healthful use of its complex machinery. Its adoption then should be deprecated, and especially so in our schools and stores. The shape of the body in the sitting posture is greatly dependent upon the position of the arms and head. The one which best maintains the symmetry of the trunk, and therefore is most healthful, is that in which the spinal column balances upon the pelvis, with the arms at the sides and the head upright. The posture is the one which the body should be trained to assume in the schoolroom, the workshop and the carriage.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY FROM NOVEMBER 13, 1892, TO NOVEMBER 19, 1892.

Leave of absence for one month, with permission to apply to the proper authority for an extension of one month, is granted Major Calvin DeWitt, Surgeon, U. S. Army.

The leave of absence for (7) seven days granted Captain W. W. R. Fisher, Assistant Surgeon, U. S. Army, is hereby extended fourteen days.

First Lieutenant, Henry R. Stiles, Assistant Surgeon, (recently appointed) is assigned to duty at Jefferson Barracks, Missouri.

First Lieutenant, Paul F. Straub, Assistant Surgeon (recently appointed) is assigned to duty at Fort Riley Kansas.

First Lieutenant, Francis A. Winter, Assistant Surgeon, is relieved from duty at Fort Riley, Kansas, and assigned to duty at Fort Wingate, New Mexico.

First Lieutenant, A. E. Bradley, Assistant Surgeon is relieved from duty as attending surgeon, Hd-qrs., Dept. of the Platte, Omaha, Nebraska, and is assigned to duty at Fort Sully, South Dakota.

Captain Benjamin Munday, Assistant Surgeon, is relieved from duty at Fort Sully, S. D., and is assigned to duty at Fort Nebraska, Nebraska, for duty.

First Lieutenant, Harry M. Hallock, Assistant Surgeon, (recently appointed) is assigned to duty at Fort McPherson, Georgia, for duty at that post.

First Lieutenant, Robert S. Woodson, Assistant Surgeon, is relieved from duty at Fort McPherson, Georgia, and is assigned to duty at Fort Barrances.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

MEDICAL USE OF ERGOT.*

By KATHARINE MILLER, M. D.,
LINCOLN, ILL.

Ergot, like many others of our valuable remedies, began its therapeutic career in the hands of those outside our profession. It was in somewhat common use among German midwives as early as 1688. Nothing further was heard of it in medical circles until 1774, when mere mention again occurs. In 1777 M. Desgranges, of Lyons, began using it, and published several articles on its use during the following years. Before its use became common in France, however, Dr. Stearns, of New York, introduced it to the profession in this country. In 1820, Dr. Merriam, and 1825, Dr. Davis published articles on it. Thereafter its use in obstetric practice became common. Of its use in other than obstetric cases no mention is found until much later, and its general effect on the system seems not to have been carefully studied. Early observers concluded that "it acts on the uterus entirely through the nervous system; that its influence is septic, confined principally to the uterine organs, and the pulse is only secondarily affected, in consequence of the increased action of the uterus. In many cases it has appeared to diminish the frequency of the pulse." Dr. Hardy, from accurate notice of a large number of cases in which ergot had been administered, came to the conclusion that it diminished the frequency not only of the mother's pulse but also of the child's. With the spread of its use in obstetric practice and for other uterine difficulties involving hæmorrhage or other profuse discharges, a natural curiosity led some to try it in other diseases until in 1877 the United States Dispensatory mentions its trial in hæmoptysis, gonorrhœa, dysentery, diarrhœa, paraplegia, vesical and rectal paralysis or paresis, spermatorrhœa, hysteria and intermittent fever, and Dr. George B. Wood inquires: "May it not have the power of producing contraction in capillaries in general, or of interfering in some other way with the circulation of blood in the vessels as by the exertion of a direct sedative or paralyzing effect?"

Meanwhile, Dr. Samuel Wright had found the oil valuable as an anodyne external application in rheumatism and toothache, and as a styptic in wounds.

Most therapeutic works of reference of that time, however, dismiss, with a mere mention, all except the uses dependent upon uterine action, even pronouncing ergot without influence on man.

As late as 1841 prominent physicians utterly denied its effects on the parturient uterus. With longer use and experiment, however, the value of the drug had become gradually understood, but I have found no evidence of careful scientific study of its physiological action, beyond the effects on the uterus, earlier than about 1871, except those of Wright in 1839, and Bonjean in 1845, which are largely studies of its poisonous action in large doses on animals. The complexity of the substance has made it more difficult of study. Different methods of preparation have secured different extracts varying in constituents and effect, so that the details of its action admit of large latitude of argument and controversy. Probably the preparations representing the drug most completely are a reliable fluid extract, and Bonjean's ergotine, a well-prepared aqueous extract entirely different from the active principle which the name suggests. There is no longer doubt that ergot ex-

* Read before Illinois State Medical Society, 1892.

cites the vaso-motors and certain other nerves of the ganglionic system. Upon its effects upon the vaso-motors, most of its usefulness in general practice depends; though doubtless the effects on other nerves or centers must be considered in its action on the bladder, and, to some extent, on the walls of the intestines. It seems, indeed, to affect the motor nerves of unstriated muscle in general, probably through action on the nerve centers rather than on the peripheral nerves, though there is evidence that certain elements, especially those not found in the aqueous extract, affect the peripheral nerves. The most prominent effect, aside from its uterine action, is on the caliber of the arteries or arterioles which become markedly contracted under its action. This results obviously in a great rise of blood pressure. Accompanying this, and probably in part due to it, is a slowing of the heart-beat. Several experiments have shown this effect to be mostly due to action on the peripheral cardiac pneumogastrics. This slowing may amount to ten to thirty-five beats per minute, but rarely, if ever, is the pulse reduced below sixty. The amount of contraction of the caliber of vessels under the influence of vaso-motor stimulation is very great, and as the drug is not very rapidly eliminated, it has a certain persistency, requiring some time to relax completely when under control of full physiological doses. Ergot in toxic doses, as would be expected, causes a paralysis of the nerves, and arterial dilatation follows. It is probably due to exhaustion of the nerve centers by over-stimulation, but of course the factor of muscular exhaustion with lack of irritability and failure to respond to nerve influence may well be also a factor.

That ergot influences other unstriated muscles than those of blood vessels and the uterus is beyond question. In large doses it excites in animals very active intestinal peristalsis. It is probable that decidedly large doses are needed to produce this effect and no data are given pointing to any usefulness from this section in the treatment of disease, though it would seem that in peritonitis or enteritis with congestion and threatened intestinal paralysis it might be indicated. Its effect on the muscular structure of the bladder is more available, and here, as in the uterus, it seems to stimulate the sphincter muscle even more than those of the fundus. It is therefore useful in paralysis of the bladder, but more especially in paralysis or imperfect development of the sphincter vesicæ with consequent imperfect control of urine, as in the incontinence of childhood with undeveloped sphincter, and of age with atrophy of the muscles or exhaustion of the spinal centers through disease. The weight of evidence showing that these results are in part due to peripheral action, the use of ergot in full doses is rational, if not otherwise contra-indicated, where there is paralysis vesicæ or paralysis of the sphincter vesicæ from spinal injury affecting the vesical centers in the cord. The possible contra-indication would lie in the effect of the treatment on the primary injury.

Ergot has been considerably employed with satisfactory results in various diseases of the spinal cord. Its use is recommended in spinal congestion by no less authorities than Brower, Hammond, Spitzka, etc. It is true that testimony is not unanimously favorable. So prominent a therapeutist as Bartholow says that ergot induces an anæmia of the arterial distribution, an ischæmia properly speaking, but the blood that is driven from the arterial side accumulates on the venous side, hence while the arterial supply may be reduced, the veins of the spinal canal are unduly distended. This statement, however, seems based on unusual conditions, since the increased arterial pressure could not result in venous distention unless it were sufficient to react through the pulmonary circulation and the right heart. This could only happen in cases of insufficiency in the left heart from lesion of the aortic valves permitting the increased blood pressure to be so transmitted backward. It appears evident, however, that so long as the heart continued fully competent for its work the lessened arterial supply must result in lessened venous supply, allowing over-distended veins an opportunity to recover themselves. The danger of regurgitation acting injuriously is lessened by the fact that the vaso-motors of the lesser circulation under normal conditions are less promptly acted on by ergot than those of the systemic circulation, so that the dosage of ergot sufficient to cause active contraction of the systemic arterioles with great increase of blood pressure there would have less effect on the pulmonary

circuit. It must be remembered too, that venous tone is increased by ergot, so that the veins are not entirely helpless in the face of the possible catastrophe. The complexity of these relations and the possibility of error in the use of this as of other powerful remedies, merely show that the physician who is a successful therapeutist must mix and apply his medicines as the artist Opie mixed his colors, "with brains."

Ergot has been used in spinal scleroses for relief of lightning pains with good success, but there is reason to fear that in such cases it merely operates by hastening that pathological destruction of elements which would otherwise after longer delay, have secured the same result, relieving nerve irritation by securing starvation and extinction of the nerve elements. In acute congestion and inflammation of the spinal cord, and of the brain as well, ergot has an undoubted value, restoring the tone of vessels dilated or overcharged with blood, relieving the nerve elements from pressure and assisting in the return to normal conditions. In this way congestive hemicrania as well as other forms of headache attended with active or passive hyperæmia may be relieved.

The effect of the active contraction of vessels in other regions is equally favorable. It has been utilized especially in pulmonic congestions, pneumonic and otherwise. It is true that the pulmonary vaso-motor system seems less easily affected than the systemic, yet when a condition of vaso-motor paresis or vaso-dilator irritation (as the case may be) exists, the response is prompt and not attended with unpleasant symptoms from increase of blood pressure throughout the body.

The usefulness of ergot in pulmonary hæmorrhage has been recognized for some time. Its use to prevent the onset of hæmorrhage and even the slight escape of blood accompanying pneumonic congestion would seem to follow naturally but appears not to have been appreciated. Early in my practice a case occurred which proved an effective object lesson to me. A four year old child of a friend of mine was ill with apparently a simple catarrhal fever; as I sat watching her, the quickening breathing attracted my attention. Physical examination showed pulmonary congestion beginning. Cardiac depressants were promptly used and counter-irritation applied to the chest. Two or three hours passed with steadily quickening respiration and harder laboring heart marking the progress of the disease. It seemed as if the vessels of the lungs were paralyzed and filling to distention with blood. I reflected that ergot ought to control that condition and began using it; ten drops of the fluid-extract every fifteen minutes; then as the effect began to appear a dose each hour. In two or three hours more the child was out of danger, the heart beat slower and fuller, the labored, quickened breathing passed away and the case resolved itself into its former simple catarrhal condition. In few cases has the physician had the opportunity to act so promptly, but in many a case I have seen excellent effect in limiting such trouble when too late to entirely prevent it.

In certain cases of severe irritating cough accompanying the influenza of the past winter, ergot has been very useful. The condition appears to be an intense congestion of the bronchial mucous membrane without exudation; indeed the membrane is abnormally dry. At a meeting of the Brainard District Medical Society, Dr. Hurst of Greenview, reported a fatal case where atelectasis apparently occurred, there being seemingly absolute adhesion of the dry inflamed surfaces of the smaller air passages. Expectorants utterly failed to relieve these cases. Sedatives gave at most temporary relief. The cough was most trying to the patient. Believing the condition to be as described, I prescribed ergot freely and in the several cases where I used it, the result was a prompt alleviation of the extreme annoyance and a reduction of the condition to that of an ordinary bronchitis. The cases were too few to make broad statements therefrom, but they certainly point to the possible relief of a condition most difficult to control and of a really serious nature.

The effect of ergot on hæmorrhage wherever occurring is excellent, though it cannot act quickly enough nor probably are the muscular fibres capable of sufficient contraction to check hæmorrhage from very large vessels. In pulmonary hæmorrhage as mentioned, in renal or vesical or intestinal hæmorrhage and in many cases of cerebral hæmorrhage its good effects, if used in efficient doses, will be manifest. Even in passive hæmorrhage from venous obstruction, its action may at times be

reasonably invoked, especially if a rapidly beating heart with a low blood pressure is forcing more blood upon the congested area. By slowing the heart and encouraging more complete filling of the ventricles, the pulmonic circulation may be relieved with relief, hence, to the right heart and systemic veins. Through this action also ergot proves an efficient adjuvant to digitalis or other heart stimulants even in cases where no oozing of blood under venous pressure has yet occurred. A condition frequently met with is that of the intestinal hyperæmia accompanying diarrhœa, dysentery and enteric fever. As might be expected, ergot is most successful in the cases where a chronic congestion and diarrhœa follow an acute attack, where, in fact, the continuance of the discharge is due to the increased secretion caused by relaxation of the vessels of the intestinal mucosa with over-nutrition and increased activity of the secreting epithelium. In cases where a poisonous ptomaine exists, or where the intestine has become a culture tube for pathogenic bacteria, ergot will prove useless until these are removed. It must therefore, be combined with other remedies in acute dysentery when its use is indicated by the hæmorrhage accompanying the disease.

The occurrence of hæmorrhage is so much dreaded, the destruction of tissues following intense hyperæmia of certain regions of the intestines so well recognized in enteric fever that the use of ergot as a preventive of these unfavorable symptoms can but be logical. To wait until intestinal hæmorrhage occurs, or to allow intense hyperæmia to persist for days or weeks, is to invite an unpleasant issue. The remedy which promises help in such a case is equally willing to act as a preventive. Ergot in such cases is not comparable to the direct astringents which may be given later, in the hope of their reaching the diseased spot and exercising a local effect, nor is it open to the objection to their prophylactic use that they lock up the bowels with possibly poisonous materials within, which should pass off, checking even normal secretions and coating the bowels with more or less irritating or, at best, useless foreign material. Ergot does not check peristalsis like opium, but rather strengthens it, probably, and acting through the blood supply there is little risk of reducing the nutrition, and hence the secreting capacity, of the epithelium below the normal, nor does its use interfere with the use of other remedies which may be indicated. It helps to prevent the hypostatic pneumonia so much feared, and in the moderate doses available as a prophylactic measure it may be continued for some weeks without derangement of digestion.

It would prolong this paper too much to dwell upon its use in splenic enlargement and leucocythæmia, night sweats, aneurism, galactorrhœa, diabetes insipidus, etc., to enumerate all the various forms of disease to which its ability to cause contraction of the unstriated muscle and to slow the heart's action render it adapted.

In conclusion, therefore, let me affirm that ergot used in free doses within physiological limits has a wide field of usefulness in general practice, and to emphasize the value of its use as a preventive of hæmorrhage and other accidents due to vascular distention or rupture and liable to occur in a large number of diseases. That its efficient dose is often large, and that the long continued use of such doses or their use at all under some conditions where increased blood pressure is dangerous, has certain risks, should not be to a rational physician a reason for omitting from his armamentarium a valuable remedy.

DEAFNESS OF LONG STANDING CURED IN A FEW DAYS.*

DR. HOVENT,
BRUSSELS.

Chance often does wonderful things. More than one instance could be cited where it has powerfully assisted Nature in rendering futile the efforts that Art has made against her. In the remarks set down here, Nature, the *vis medicatrix*, was not opposed in her healing action, but

**Revue de Laryn. de Otol. et de Rhinol*, Nos. 17, 18, 1892. Translated for the MEDICAL AND SURGICAL REPORTER by M. B. Werner, M. D.

alone she was impotent, and Art had only lent her questionable aid. Chance intervened, and, "did wonders."

In the beginning of last January, Prof. Verriest (de Louvain) recommended compressed air baths to one of his patients who had some affection of the respiratory organs. The patient was a young boy, and was usually brought for treatment by a friend. On the 8th of January his companion Rachel P., who was deaf, shared his air bath. After being shut up for two hours, on coming out, the girl told me joyously that under the bell she had heard perfectly well, and that at that very moment she could hear better than usual. After having found that she heard the ticking of a watch at the distance of seven cm. only, with both ears, I begged her to send her parents to me, in order to find out more about her affliction. On the 10th of January the mother came to my office, she had tried everything she told me, which might cure her daughter, she could could do nothing more. She had consulted specialists who had told her that compressed air might be beneficial; one had just procured for her a little apparatus, by which the drum could be massaged; this was the only remedy she still intended trying. These details were very important for me, since the last specialist consulted had advised massage of the drum, he evidently thought it was affected. I blindly accepted this diagnosis and also advised massage, not however by a portable apparatus, but soft, continuous, uniform and progressive, such as only compressed air baths can produce. The treatment was begun on the 10th of January and after sixteen seances given in the course of eight to ten days, the cure was complete.

Jan. 8th. After the first ordinary seance *aëro-therapique* Miss P. hears the ticking of a watch at a distance of 7 cm.

Jan. 10—	After	1	special	seance	9	cm.	r. ear,	8	cm. l. ear

" 20—	"	2	"	"	46	"	"	46	" "

On the 20th of January the little girl could hear as distinctly as her mother, and as the other people about her. A remarkable incident was that on the 13th of January the mother refused to have her child treated any longer, because the little girl had said she could not only hear when people talked, but also heard all sorts of strange sounds that she had never heard before. Dr. Bribosia had observed something similar in one of his patients a girl of 15 years, who, "really could not believe her own ears, when she heard sounds she had never before heard, but which to us sound quite natural. She thought she was a victim of hallucinations. By inspection of the numbers written down in reference to Miss P.'s case, one can readily see how the treatment was followed by regular progressive improvement from the beginning. The gain obtained after each seance was at first only 1 to 2 cm. and reached a limit that can be considered normal on the 14th of January. Before a cure had been reached, Miss P. had been obliged to suspend treatment for three days, and in consequence her hearing diminished two inches in each ear. This was a peremptory reason to continue the treatment a few days after the cure was considered complete. The little girl left us on the 24th of January. During the month following we had excellent reports of her, when suddenly she contracted a heavy cold and became as deaf as she had been before the cure. Experience told me that one seance like the former ones, would be sufficient to give her back what she lost, but I prescribed for the cold only inhalations and a gargle based on *Acidi Phenique*. Eight days after this treatment her cold as well as her deafness had disappeared.

On the 23rd of April I again saw Miss P. , her hearing was perfectly normal; but was the cure permanent? Would deafness not return after a severe cold through which the respiratory organs would be affected? I felt sure that the cure was complete, and this proved to be the case, since during the month of May she was quite ill, accompanied with high fever; this latter disappeared after a single air bath, and antiseptic treatment for three days completed the cure.

The facts can be summoned up as follows: Under the influence of a few air-baths, the sense of hearing has been rapidly established in a person who had given up all hopes of ever being able to hear. All buzzing in the ears had disappeared, the nasal canals being unob-

structed, the heavy breathing by mouth is no longer necessary. The exaggerated susceptibility to inflammation of the mucous membrane is done away with. I imagined that by massage I had given to the tympani their elasticity, but Mrs. P. thought otherwise. "No," said she, "the drums were not attacked, the massage of the drums had nothing to do with the cure. You must find another reason for it." I later found she was right. The little girl in question who is now over thirteen years old enjoys very good health though she still is subject to an attack of sore throat every two weeks, and this tendency has existed since her earliest infancy, and was the cause of her deafness. Many specialists were consulted but only the treatment of one of them, Mr. Bager, of Brussels, proved of value. He removed by operation the obstruction in the nasal passage thus making breathing easier. This was followed by catheterization of the eustachian tubes, the results were admirable, but Dr. Bager admitted that a complete cure was impossible without resorting to more energetic measures. After a year of continuous care the patient left Dr. Bager to go abroad. Catheterization was practiced by an awkward hand, disastrous results followed, she became worse; she came to me and was cured.

The natural sequence of catarrh is obstruction of the Eustachian tube. Dalby tells us this is quite a common occurrence in people of all ages, but principally in children. Prof. Moure considers it as a frequent complication following syphilis of the nose, or of polypus, etc., etc.

Politzer, Bergold, and more recently Loewenberg, have made the following statements: "The membrane tympani sometimes retracts *ad maximum*; this is a constant phenomenon in catarrh of the ear and we conclude that deafness is an indirect consequence of the obstruction of the eustachian tube. The treatment directed against this obstruction as practiced to-day seeks to reestablish free passage and at the same time to relieve the congested mucous membrane."

The air-bath alone can produce these desired results, its action can be compared to a soft, continuous, progressve, powerful, *air catheterism*, which penetrates the cavity of the ear, and does away with any foreign body. The compressed air bath has a powerful effect on the capillaries of the mucous membrane, it acts as a tonic, and Paul Bert remarks that the augmentation of the *barometrique* pressure increases the tension of the oxygen in the blood.

In 1820 Dr. Hamel, physician to the Court of Russia, wrote, that the diving bell could serve as a remedy in the case of deafness produced by the obstruction of the eustachian tube. Dr. Colladon, 1826, in his remarks on compressed air, states, that a diver never becomes deaf, but on the contrary it seems that in certain cases the action of the diving bell might serve as a remedy for deafness. Since 1836 when Tabarie introduced the compressed air bath as a treatment for deafness, thousands have obtained cures by it. It has been chiefly used in treating phthisis, bronchitis, anæmia, and diabetes. It is generally admitted at the present time that compressed air-baths administered prudently and systematically can do no harm in any case. The fever which follows is not a bad indication. Prof. Germain Seé of the Paris Académié de Medecine says he has known the temperature to be 37° C., in the morning and 37.5° C. in the afternoon, but generally becoming normal after a short time.

Prof. Lazarus of the Society of Medicine in Berlin, remarked that the care exercised at present in the administration of compressed air baths makes it permissible to use them in cardiac affections. *La Sclirose Arterielle* even in advanced degrees does not contraindicate its use. The action of these baths has been compared to that of digitalis.

M. Mœller states that the question of treating heart disease with the aid of the compressed air bell, has not yet been solved, but that it has been demonstrated that during the time the patient receives the treatment, there is a marked change in the blood pressure, decreased arterial and increased venous, the respiratory movements are diminished and the respiratory murmur is prolonged; this seems to indicate some difficulty in the pulmonary circulation; in the case of extreme weakness this treatment could but hasten the end.

On the other hand others say that in *every* case compressed air baths can only be beneficial, and as they invariably augment the appetite, an increase in vitality could not fail.

Conclusions: 1.—Catarrhal affections of the digestive or respiratory organs often result in an inflammation of the pharyngeal orifice of the eustachian tube causing deafness; the symptoms are often misleading, and may produce the supposition that the origin of the defect is in the internal or external ear.

2. The obstruction of the eustachian tube may be benefited or cured by compressed air baths.

3. The compressed air bath is the most efficacious massage treatment for the tympanum.

4. A cure by air baths will prevent the return of intermittent attacks, due to coryza, anginæ, laryngitis, bronchitis, catarrh of the drums, otorrhœa, etc.

When the patient is quite young a complete cure can be obtained by air baths, even in the most desperate cases; in adults they will produce the same results as long as the acoustic nerves are not completely degenerated.

6. This treatment for deafness differs entirely from that applied to other affections.

7. Cardiac affections as well as a state of low vitality, which have been considered contra-indications, will on the contrary be markedly benefited by a systematic prudent administration of compressed air baths.

A CASE OF EXTENSIVE HEMATOCELE RESULTING FROM TUBAL PREGNANCY RUPTURING INTO THE BROAD LIGAMENT.

By W. D. HAGGARD, M. D.,
NASHVILLE, TENN.

Miss K. C., house-girl, age 24, jumped from an express wagon, July 4th. Her menses were past due. Shortly afterward she was seized with pain in lower abdominal region, which grew worse during the night. Next morning a slight flow from the vagina was apparent which she regarded as a return of her menses. For several days the discharge increased and the pain gradually grew worse. One week after the accident the family physician was called. He proposed vaginal examination but was refused. Opium and ergot administered without effect.

One week later another physician was called, who likewise asked for a vaginal examination, but without avail. At the expiration of the third week, there was no improvement and the patient was taken to the Catholic Hospital. Dr. Coyle, the physician-in-charge, found an ovoidal tumor as large as a cocoanut above the symphysis pubis. It was very tender, non-fluctuating, and occupying almost a central position. As a vaginal examination was denied, he supposed the tumefaction to be a gravid uterus. The patient became dissatisfied at the hospital and returned home. On the 29th day I was called to see her, to meet Dr. Coyle in consultation, to whom I am indebted for the foregoing history.

THE EXAMINATION: Patient was found anxious, restless and impatient, suffering greatly from pain in lower abdominal and pelvic region. Temperature, 103°; pulse, 120; skin, hot and dry; tongue, heavily coated; intense headache; globular tumor above pelvic brim, so tender as not to permit of palpation. Bowels, tympanitic and tender throughout. Vaginal examination revealed left lateral pelvic space completely occupied by a non-fluctuating tumor, so exquisitely tender as to preclude a thorough examination.

The tumor in the hypogastric region was supposed to be an extension of the enlargement. The womb was closely hugging the symphysis, the external os, patulous and on a level with the arch of the pubes.

Her condition was most critical, her position as a house-girl anything but consoling. The possible rupture of the escapsulating peritoneal membrane with escape of contents into the general peritoneal cavity and the inevitable peritonitis was feared. Vaginal puncture and drainage were discussed and discarded. Section was urged as the only hope. Dr. Duncan Eve, who was added to the consultation, concurred. The patient, after a day's hesitation, consented to operation and was removed to St. Margaret's Hospital.

THE OPERATION: Twelve M., Sunday, August 7th, 1892. Took ether badly. Median incision. Anterior wall of tumor was adherent to parietal peritoneum, hence, they were incised together. The operation was practically extra-peritoneal. About three pints of dark, clotted blood turned out. Care was taken

not to break down the partition wall which so effectually walled off the hematic tumor from the abdominal viscera. The sac was quickly and thoroughly irrigated, sponged dry and the operation hurriedly completed. She rallied badly. The intense pain and restlessness which had been partially controlled by morphia for the last thirty-six hours became uncontrollable. She died at 12 P. M., twelve hours after operation.

POST-MORTEM. Two hours after death, under great disadvantages, incisions reopened, adhesions between sac and abdominal wall broken. The entire abdominal viscera of deep modena color, matted together in places from peritoneal inflammation. No blood found in abdominal cavity. Pelvis carefully examined, viscera fused together in a conglomerate mass. Uterus sought for and found enlarged, tubes not recognizable. The pelvic viscera removed *en masse*. The rectum adherent and perfectly black. Uterus measured antero-posteriorly, 1½ inches. Transversely, 2⅝; longitudinally, 5½ inches. After removal the mass was spread upon a plane surface and photographed, from which a drawing was made. The distended broad ligament, forming the sack, was greatly thickened.

MICROSCOPIST'S REPORT: "The specimen (endometrium) given me for examination was submitted to the usual procedures and found to consist of large embryonal cells completely filling the spaces of a myomatous reticulum. The cells were clearly the so-called 'decidual cells' having a round or oval shape and containing one or more nuclei; they varied in size, having a general average of about one-four-hundredths of an inch in diameter, or eight times the diameter of a red blood corpuscle.

"Remnants of utricular glands were present, but not numerous. Groups of connective tissue corpuscles were scattered here and there. The specimen showed clearly that decidual formation had taken place." HUGH R. MILLER.

Although the fœtus was not found, that it was a case of tubal pregnancy with rupture into the broad ligament is clearly established by the clinical history and post-mortem appearances, which may be summarized as follows:

1. She confessed having had intra-pelvic trouble previously (presumably gonorrhœa) for which she was treated locally.

2. At the time of the accident, caused by jumping from a wagon, her menses were past due. As to how long, her statements were misleading.

3. There was a fitful yet persistent bloody flow from the uterus during her entire illness.

4. Paroxysmal, colicky pains in lower abdominal and pelvic regions of frequent occurrence.

5. Existence of a tumor above the pubes, which she probably mistook for a gravid uterus.

6. Persistent refusal to submit to a digital examination, probably fearing the detection of her pregnant state.

POST-MORTEM APPEARANCES.

1. Enlarged and softened condition of the uterus with a patulous os showing escape of a sero-sanguinal, stringy fluid.

2. Enlargement of the left tube with a well-defined cavity from which the fruit sac escaped.

3. Existence of a deciduous membrane, as revealed by the microscope.

4. Discoloration of rectum, produced by blood dissecting around it, causing constriction and partial death.

Clinical Lectures.

OSTEOCLASIS.*

BY NICHOLAS GRATTAN, F. R. S. C., ED.

SENIOR SURGEON COUNTY AND CITY OF CORK HOSPITAL FOR WOMEN AND CHILDREN. GIVEN AT DR. LEWIS A. SAYRE'S OPENING CLINIC AT BELLEVUE HOSPITAL, NEW YORK CITY.

DR. SAYRE'S INTRODUCTION.

Gentlemen:—One year ago to-day I had the pleasure of introducing to you Sir William McCormac, of London, who gave a clinic on resection of the elbow joint, performing the operation upon an arm condemned to amputation. Now the patient writes the House Surgeon that he has a good, useful arm, though not perfect motion of the resected joint. To-day I am glad to have the pleasure of introducing to you Dr. Nicholas Grattan, a distinguished surgeon, of Cork, Ireland,

* Reported by B. F. Parrish, M. D.

[A resume of this lecture was given in the last issue. It is now given in full with a cut of the instrument.—ED.]

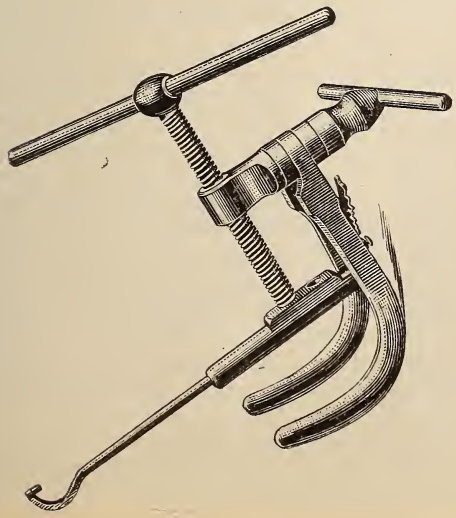
who will give you a lecture upon Osteoclasis.

Mr. Grattan said:

Gentlemen:—Dr. Sayre has honored me by permitting me to detail to you an account of my work with an osteoclast.

You are aware that, there are two methods of performing osteoclasis—1st, manual; 2nd, instrumental. It is the latter mode of procedure with which I will deal. The instrument which I use consists of two curved bars which can be approximated or separated as may be desired. These bars are connected together by means of a strong pivot, to one end of which is attached a cross-bar for the purpose of preventing the instrument overturning when in use.

Through the other end of the pivot the screw works, to the end of which is attached the handle. The other end of the screw is fitted into the pressure bar. The pressure bar is straight. The part through which pressure is applied to the limb is oval in shape in order to prevent its cutting the skin. A long rod is inserted into the end of the pressure bar to prevent its rotating on the limb when the screw is turned. The three bars are sufficiently long to prevent their *entering* and cutting the skin. The curved bars which oppose the pressure bar are cylindrical in shape. A rachet, each division of which corresponds to openings in the curved bars half an inch each, is placed underneath the pressure bars, the use of which is to prevent the curved bars from being forced together when the pressure is applied.



From time to time I have had the pressure bars covered with felt or india rubber, but I find that this is unnecessary and that the best results are obtained by having them highly polished. In my practice my endeavor has been to fracture the bones with the curved bars as near each other as possible. By so doing I obtain more accurate results. In my first case I had them at a distance of from 2 1-2 to 7 inches apart, varying with the age of the patient. Now I use them from 1 1-2 to 4 1-2 inches apart,—just half the distance of two years ago. I have had some slight skin wounds, and in cases of knock-knee I regard this of little importance. I prefer in such cases to make my fracture as close to the knee joint as possible. In cases of bow-legs I do not apply so great pressure and avoid, if possible, having skin wounds.

In operating on a femur for genu-valgum one curved bar of the osteoclast is placed on the outside of the femur just above the condyle, the other curved bar is placed from 1 1-2 to 4 1-2 inches higher up the limb according to the age of the patient. The oval bar, in which the end of the screw works, is applied to the femur on its inner side *transversely*, midway between the other bars. The three bars are held in position on the limb by an assistant, who must prevent the pressure bar from rotating by grasping the long bar, which is inserted into it. The assistant must also take care that the pressure bar does not compress the femoral vessel, and that *the skin* under the pressure bar is *quite loose*; otherwise it will be more apt to tear.

All being ready, the operator turns the screw quickly and forcibly, until the bone is felt or heard to break. The screw is then rapidly reversed to relieve pressure. After the bone has been broken and the osteoclast removed, the operator takes the limb in his hands, feels that all the fibres of the bone have been torn across, and sets the ends together in their new position. I usually employ a long splint, curved like a cask stave, to retain the limb in its new position.

I always *over-correct* my cases of *knock-knee*, and invariably use some method of extension in treating such cases, usually the weight and pulley. On the 9th or 10th day I examine my cases and if not sufficiently corrected readjust them into

any desired position. In some cases I have found it necessary to fracture the bone of the leg quite close to the knee joint in order to correct the deformity of knock-knee. Owing to the complicated anatomical arrangement of this part of the limb I regard this as a serious procedure and to be performed with the greatest caution.

Bow-legs are easily corrected by means of this instrument. In these cases the pressure bar is applied on the outside of the limb. In cases of anterior curvature of the tibia the pressure bar is also applied at the outer side of the tibia, and not on the front of the shin. In cases of osteoclasis of the lower extremity I lay down this rule: Always apply the pressure bar where you are least likely to do mischief. An anæsthetic is always to be administered during any operation, or any painful manipulation.

You are aware that in many cases the deformity of clubfoot is in part owing to defective fœtal unwinding of the lower extremity. In many of these cases the entire extremity is involved in the deformity. After correcting the foot I have several times fractured the tibia and fibula quite close to the ankle joint, and again in the middle third of the limb. I have by this means been able to correct the inversion of the foot which is so common in those cases, and the fracture close to the ankle joint has enabled me to get the foot more flat on the ground than I otherwise would have done. I have also crushed the tarsus and corrected many cases of flat foot with this instrument with the best results.

N. B.—During the hour Dr. Grattan operated upon four children. Three of them were children about three years of age. All of these had double genu-valgum. The fourth patient was a girl, 19 years old, with single knock-knee. All seven legs were easily broken just above the condyles of the femur. Some of them were put up with Buck's extension and the long side splint. The others were put up in plaster of Paris. In the case of the 19-year-old girl the skin was broken for a short distance by the pressure bar. The Doctor claimed that this is the only injury ever done when the operation is properly performed and that it was of no consequence.

During the lecture the Doctor passed around a knee joint which he had taken from a little girl 3½ years old. The child died ef tubercular meningitis 3½ months after he had performed osteoclasis upon both femurs for double knock-knee. The specimen was a very perfect and instructive one. It showed the bone perfectly healed without callous. There had been no injury to the softer tissues. The motion of the joint was perfect.

Since this lecture was delivered the cases operated upon have been observed in the wards of Bellevue Hospital. The patients have all made good recoveries with excellent results. The one patient with Buck's extension and Liston's long splint had a temperature of 101° with pain for several days. The legs were then redressed in plaster of Paris and elevated. After this the temperature fell and the patient had no more trouble. All the other patients were dressed in plaster of Paris and had their legs suspended from the first. None of these patients had the slightest trouble.

The accompanying cut shows Dr. Grattan's instrument as made by Mr. Robert Linder, of New York City.

SULPHONAL.

CHARLES. M. BUCHANAN, M. D.
WASHINGTON, D. C.
PROF. CHEM. TOX., AND METALLURGY, NATIONAL UNIVERSITY.

Modern bibliography is particularly poor in information as to the special toxic properties of this new hypnotic and soporific. Here we are, most of us, sadly deficient in a knowledge of the toxicology of the drug. Such a condition of affairs behooves the profession at large to report in full any case throwing additional light upon the nature, action, properties and toxicity of not only sulphonal but of every new and untried aspirant for professional favor. It is only in such manner that we can hope to learn much of practical value concerning them—*per aspera ad astra.*

There have been published of late twenty-nine or thirty cases of poisoning attributed to sulphonal. It is stated that the chief symptoms were "dullness and stupidity of mind; prostration; more or less paralysis of body, and chills, vomiting

and diarrhœa. Death occurs from heart failure and œdema of the lungs." Here we have, as it were, a word picture of a person rendered moribund by sulphonal. One case, I remember, reported death from a half-ounce dose, that is, 240 grains. Another writer says "The harmlessness of sulphonal is not established by facts, although it may be by fancy." My experience with the *toxicity* of the drug is not sufficiently large to either affirm or deny, being limited to one case followed by recovery.

On the afternoon of the seventh day of May, was called in great haste to see Mrs. X., a most talented and accomplished person and a lady of great social prominence. Found her sitting up in bed, talking and fussing away at her nurse and trying to rise. She could not keep still; when she eluded the nurse, she paced up and down the room with unsteady gait muttering to herself all the while; while restrained in bed, she wrung her hands and cried, with thick speech, for "something to help her." This appeal seemed to be more mechanical than from any realization of her condition. Skin of darkish, bluish tinge, lips purple, pulse increased slightly in frequency but somewhat deficient in strength. Respiration only slightly embarrassed. Mental receptivity exceedingly impaired, bordering on almost total mental inhibition; physical excitation, causing movement of limbs and body. No prostration, paralysis, chills, diarrhœa or vomiting. Apparently there was a condition of weakness and depression of the cardiac apparatus, with almost complete loss of the mental faculties coupled with great muscular excitation.

On inquiry found that the patient was addicted to the use of liquor at times and also probably of morphine. Of late had been using sulphonal, buying it in bulk by the ounce. She had taken half the contents of an ounce box when the nurse, alarmed at the large doses which she took, hid the remaining half-ounce in a room adjoining. During the temporary absence of the nurse, she sought, found and took the half-ounce which had been secreted. Then ensued the condition above described.

This happened about three hours before I had been called, emetic draughts of hot water and mustard having been ineffectually administered in the meantime. Inasmuch as three hours had elapsed I deemed it useless to attempt emesis. Administered about an ounce of whiskey, and twenty grains each of chloral hydrate and ammonium bromide in tinctures of cinnamon and cardamon and elixir of orange. Left directions to repeat the dose in four hours if she did not sleep. I gave the whiskey for its stimulating effect and the chloral to calm the muscular excitation and produce physical rest. I preferred chloral to opiates on account of the condition of the patient's heart and her probable addiction to opium in some form.

She slept well, and awoke the next day practically in prime condition. Here is a "lady and the tiger" case—which cured, Nature or the medicine?

BOWEL OCCLUSION—AN EMERGENCY CASE.

By GEORGE R. DEAN, M. D.,
SPARTANBURG, S. C.

Surgeons are often puzzled over the diagnosis of acute abdominal troubles, and when suddenly called to a case where there is extreme urgency, and it is of the utmost importance that no mistake be made, this lack of knowledge is very keenly felt. All who have an experience in such cases can testify to the anxiety and worry they cause—and where a life is at stake the conscientious man will not be satisfied with guess-work.

Cases so often occur with symptoms that are not described in the books, that the surgeon must, in a great measure, depend upon his own surgical knowlege to unravel the thread of symptoms presented, and out of mystery to arrive at a correct diagnosis. It is easy to prescribe when the true pathological conditions are known. Cases involving the peritoneal cavity and viscera within, are often of such urgency and so marked, that a knowledge of the real trouble is hard to attain. Here, to be of service to our patients, we must decide our course of treatment early and fearlessly put it into operation, or we are doomed to see our efforts utterly ineffectual.

Having recently passed through an experience of this nature, and feeling how much experience, in such cases, would be of service to one suddenly confronted by a problem of this kind, in which a human life is involved, I have concluded to report

the following case: I was called eight miles from home on Friday, July 10, to see a young man, E. F., suffering with some intestinal trouble.

I found him in bed, with a good, full pulse, 102; temperature, 102.5°; respiration, 24; there was pain in the hypochondriac region, with some tenderness; the muscles of the abdomen were tense and hard; no pain except that now referred to the lower border of the liver and running back to the spine, but which, a short while before my arrival, extended down the right inguinal region. The countenance was dull and sodden; bowels had moved three times the day before, and once this morning—before I had arrived,—with frequent vomitings. These discharges I suspected were from the lower bowel, and not from the entire canal. I believed on my first visit, that I had some trouble to contend with that would involve the peritoneum, and not being willing to risk the story of the bowels moving freely, I gave calomel, gr. one-half, sodii bicarbonate, gr. ii; 4 doses at intervals of two hours, to be followed with a saline three hours after the last dose, and the use of the syringe to aid, if necessary, by enema. If these were ineffective I was to be notified early the next morning.
